American Law.—In this as in so many other departments the American law scarcely if at all differs from that of England. In so far indeed as the common law is concerned, they may be said to be substantially identical. The principal statutes which have altered the English criminal law, such as Mr Fox's Act, and 6 & 7 Vict. c. 95, are also represented by equivalent legislation in most American States. (A. G.)

LIBER AND LIBERA, among the Romans, were a pair of deities, male and female, in whose worship two very different phases exist side by side. In the country feast of the vintage, and the city festival of March 17th called

Liberia, we find purely Italian ceremonial unaffected by Greek religion. The country festival was a great merry-making, where the first-fruits of the new must were offered to the gods. It was full of unbridled rejoicing, and characterized by the grossest symbolism, in honour of the fertility of nature. It is usual to refer the name Liber to the free unrestrained character of his worship. In the city festival, growing civilization had impressed a new character on the primitive religion, and connected it with the framework of society. At this time the youths laid aside the boy's *toga pretexta* and assumed the man's *toga libera* or *virilis*. Calces of *far*, honey, and oil (*liba*) were offered to the two gods at this festival. Liber is often invoked as *Liber Pater*, and we find even the expression *Jupiter Liber*, taking us back to the primitive stage of religion when no divine hierarchy of gods had been elaborated, and when Liber and Libera were in the spheres of their cultus the sole god and goddess. Originally Liber is probably only an epithet of Jupiter.

At an early period the Hellenic religion of Demeter, common to all the Greek colonies of Italy and Sicily, spread to Rome, then Liber and Libera were identified with Dionysus and Persephone, and associated with another Italian goddess Ceres, who was identified with Demeter. At the order of the Sibylline books, a temple was built to these three deities near the Circus Flaminius; the whole cultus was borrowed from the Greeks, down even to the terminology, and priestesses were brought from the Greek cities. The temple, *Aedes Ceres*, was founded by Aulus Postumius, 495 B.C., and dedicated by Spurius Cassius, 493 B.C. The chief festival of this cultus lasted eight days, from the 12th to the 19th of April; it was accompanied by games, called *Ludi Ceresiales* or *Liberales*. The plebeian ediles, appointed about the time when the temple was founded, were closely attached to it, and from that time plebeian liberty continued in intimate relation to the *Aedes Ceres* and the gods there worshipped.

LIBERIA, a Negro republic on the Grain Coast of West Africa. Founded in 1822 by American philanthropists for the settlement of freedmen who wished to return to their native land, or to enjoy political and social privileges then denied them in the United States, it remained for twenty-five years under the tutelage of the mother country, but on the 26th July 1847 it was declared independent. In 1848 it was recognized as a sovereign state by Great Britain, which aided it in various ways, and by other Continental powers, and finally in 1861 by the United States. Its nominal boundaries are from the river Jong, a tributary of the Sherbar, in 7° 35' N. lat., 12° 20' W. long., and the river San Pedro, in 4° 45' N. lat., 6° 40' W. long., a distance of 380 miles, the limits of the state in the interior being usually stated at from 80 to 100 miles eastward, though this is unsettled, and the entire area of the country at 24,000 square miles, or 1000 miles less than Holland and Belgium combined. Like that of northern Guinea generally, the Liberian shore is low, but the country rises towards the interior, and is well-wooded and watered by numerous streams. The climate is, however, hot and unhealthy for Europeans, though of late years it has been improved by drainage, and is considered superior to that of any part of the neighbouring coast. The soil is fertile and well suited for the growth of tropical crops, such as cotton, rice, sugar, indigo, yams, ground-nuts, bananas, ginger, cassava, pine-apples, coconuts, limes, oranges, tamarinds, and the Liberian variety of coffee¹ held in such high esteem. These products, in addition to palm oil, form the main subsistence of the inhabitants, who in

return import arms, ammunition, tobacco, salt provisions, implements of husbandry, cutlery, British cottons, and other manufactured goods. Coffee, palm oil, palm-kernels, rubber, ivory, dye woods, hides, ivory, arrowroot, sugar, cocoa, ginger, and rice form the principal articles of its commerce, which is carried on chiefly with Great Britain, Holland, Hamburg, and America. Copper, gold, iron, and deposits of gum-copal exist, but they are not worked, and all the large wild animals have long since been killed or driven out of the woods. Stock can be kept in the higher lands. The government is modelled on that of the United States, and consists of a president, and a congress composed of a senate of eight members elected for four years, and of a house of representatives of thirteen members elected for three years, in addition to a supreme court, and a cabinet of the American type. One additional representative is given for each additional 10,000 inhabitants by which the population may increase. Military service in the militia is obligatory on every male citizen between the ages of sixteen and fifty, but there is no standing army. There is no established church, and all faiths are equally tolerated. The state is divided into four counties (Mezurado, Grand Bassa, Sinoe, and Maryland), and these again into townships, each 64 square miles in area. There are a number of little villages, but the only place of any consequence is Monrovia, the capital, containing 13,000 inhabitants, and in appearance very like a town in the southern United States, but in no way remarkable except for the large number of churches within its bounds. Besides Monrovia the chief ports are Robertsport, Marshall, Edina or Buchanan, Greenville, Sesters River, Sasstown, and Harper, and in 1881 foreigners were further permitted to trade at any point to the north of Robertsport. The present population of the republic (1882) comprises 18,000 civilized negroes, chiefly of American origin, and 1,050,000 half-wild natives, some of whom are adopting a settled life, and conforming to the habits of their tamed countrymen. Among the more interesting tribes are the Vei, the Bassas, the Krus, and the Mandingoes. The American Methodist Episcopal mission dates from 1833, the American Episcopal from 1834, and that of the American Baptists from 1835. The revenue of the state was returned at September 30, 1875, as 111,457 dollars, chiefly derived from customs, the national debt being 500,000 dollars, contracted in England in 1871. Of this neither principal nor interest has been paid. Socially and politically the state cannot be pronounced a marked success. The negroes in America display little desire to throw in their fortunes with it, now that they are free to go whither they list, nor do the barbarous tribes on the border of the republic seem to admire the black parody on a white man's government, which for sixty years has been presented to them. There is now and again a small immigration from the United States, but the Liberian civilization, cut off from the benefit of intercourse with a higher and broader culture, is apt to deteriorate, while neither the climate nor the laws and social surroundings are ever likely to attract many white men to its shores. It is, however, only fair to add that, though internal disorder is too often the rule, the state shows an appreciation of education and religion, and a keen desire to stand well in the good opinion of the powers with which it has relations by accredited representatives. It has formed treaties with most of the European countries, and with Hayti and the United States; and, though it has not paid its debts, successive Governments are in the habit of registering vows to meet this first obligation of a nation towards its neighbours. British coin and an irredeemable

¹ Liberian coffee (see *Coffea*, vol. vi. p. 110) has been introduced into Brazil, Ceylon, the Dutch Indies, &c. The quantity actually exported from Liberia is comparatively small.

² Maryland was originally a separate colony, founded in 1681; it became an independent republic in 1788, and about 1800 was incorporated with its older neighbour.

paper currency are the money chiefly in circulation, but all accounts are kept in United States dollars and cents. The weights employed are also British, except that gold from the interior is bought and sold by the *usano* = 16 *akis* = 16,000 cowries = 314.76 grains Troy. The *gondar-ardeb* (7.74 imperial pints), the *massah-ardeb* (2.32 imp. gals), and the *kuba* (1.788 imp. pints) are also in common use.

See Guiley's *Life of Jehu's Ashmun*, 1836, Stockwell, *The Republic of Liberia*, 1848, Wilson, *West Africa*, 1866, Hutchinson, *Impressos of West Africa*, 1868, Ritter, in *Zeitschrift für allgemeine Ethnologie*, vol. i, 1853, Brown, *Countries of the World*, vol. vi, pp. 123-127, 1881, Bowen, *Central Africa*, 1887, Thomas, *West Coast of Africa*, 1880, "Die Negersrepublik Liberia," in *Unsere Zeit*, vol. iii, 1868, U.S. Consular Reports, 1881.

LIBERIUS, pope from 352 to 366, the successor of Julius I, was consecrated according to the *Catalogus Liberianus* on May 22. His first recorded act was, after a synod had been held at Rome, to write to Constantius, then in quarters at Arles (353-54), asking that a council might be called at Aquileia with reference to the affairs of Athanasius, but his messenger Vincentius of Capua, so far from being successful in his mission, was himself compelled by the emperor at a conciliabulum held in Arles to subscribe against his will a condemnation of the orthodox patriarch of Alexandria. In 355 Liberius was one of the few who, along with Eusebius of Vercelli, Dionysius of Milan, and Lucifer of Cagliari, refused to sign the condemnation of Athanasius, which had anew been imposed at Milan by imperial command upon all the Western bishops, the consequence was his relegation to Beroea in Thracia, Felix II. (antipope) at the same time being consecrated his successor by three "catacompi haud episcopi," as Athanasius called them. At the end of an exile of more than two years he yielded so far as to subscribe the third Sirmian formula giving up the "homoeousion,"—an act which procured his immediate and triumphant return to Rome, but has ever since caused considerable embarrassment to maintainers of the indefectibility of Roman orthodoxy. The remainder of his pontificate was uneventful. He died on September 24, 366, and was succeeded by Damasus I. With the rest of the first sixty popes he shares the title of "Saint." His biographers used to be perplexed by a letter purporting to be from Liberius, in the works of Hilary, in which he seems to write, in 352, that he had excommunicated Athanasius at the instance of the Oriental

bishops; but the document is now held to be spurious. See Hefele, *Conciliengesch.*, i. p. 648 *sq.*

LIBOURNE, the chief town of an *arrondissement*, and in point of population the second town of the department of Gironde, France, is situated at the confluence of the Isle with the Dordogne, 537 miles by rail south-west from Paris, and 22 miles east from Bordeaux. The sea is 56 miles off, but the tide affects the river so as to admit of vessels of 300 tone burden reaching the town. The Dordogne is here crossed by a stone bridge 492 feet long, and a suspension bridge across the Isle connects Libourne with the adjoining Fronsac, the citadel of which, 235 feet above the sea, was at one time occupied by a palace of Charlemagne, and subsequently became an important fortress. Libourne is regularly built, but has no monuments of much architectural or historical interest, the (restored) Gothic church has a stone spire 233 feet high. On the quay there is a maculated clock-tower which is a remnant of the ramparts of the 14th century, and the town-house, containing a small museum, is a quaint relic of the 18th century. There is a statue of the Duc Dezaux, who was born in the neighbourhood. The principal articles of commerce are the wines and brandies of the district, the growths of chief repute being those of St Emilion, a short distance above Libourne, on the right bank of the Dordogne, and of Canon, a little below Fronsac. There is also some trade in yarn, grain, and wood for cooperage. Woollen stuffs and some articles of army outfit are manufactured, and nailing, tanning, shoemaking, and shipbuilding are also carried on. The harbor is used exclusively by small vessels for the export of wines; the shipping owned in the place does not exceed 2500 tons. The population of Libourne in 1870 was 15,231.

Like other sites at the confluence of important rivers, that of Libourne was appropriated at an early period. Under the Romans *Condat* stood rather more than a mile to the south of the present Libourne, where the old Gothic chapel of *Condat novus* was destroyed during the troubles of the 5th century. Reconstructed by Charlemagne, it was rebuilt, under its present name, and on the site and plan it still retains, by Edward, prince of Wales, in 1276. It suffered considerably in the struggles of the French and English for the possession of Guienne in the 14th century, and again during the religious wars, and finally in the war of the Fronde in the minority of Louis XIV. Nevertheless it ultimately outgrew both its powerful neighbours Fronsac and Saint Emilion, the latter of which is archeologically one of the most curious spots in France.

LIBRARIES

HISTORY AND DESCRIPTION.

ANCIENT PERIOD.

LIBRARIES, in our modern sense of collections of printed or written literature, imply an advanced and elaborate civilization. If the term be extended to any considerable collection of written documents, they must be nearly as old as civilization itself. The earliest use to which the invention of inscribed or written signs was put was probably to record important religious and political transactions. These records would naturally be preserved in sacred places, and accordingly the earliest libraries of the world were probably temples, and the earliest librarians priests. And indeed before the extension of the arts of writing and reading the priests were the only persons who could perform such work as, e.g., the compilation of the *Annales Maximæ*, which was the duty of the pontifices in ancient Rome. The beginnings of literature proper in the shape of ballads and songs may have continued to be conveyed orally only from one generation to another, long after the record of important religious or civil events was regularly committed to writing. The earliest collections of which we know anything therefore were collections of

archives. Of this character appear to have been such famous collections as that of the Medians at Ecbatana or the Persians at Susa. It is not until the development of arts and sciences, and the growth of a considerable written literature, and even of a distinct literary class, that we find collections of books which can be called libraries in our modern sense. It is of libraries in the modern sense, and not, except incidentally, of archives that we are to speak.

The researches which have followed the discoveries of Botta and Layard have thrown unexpected light not only upon the history but upon the arts, the sciences, and the literatures of the ancient civilizations of Babylonia and Assyria. In all these wondrous revelations no facts are more interesting than those which show the existence of extensive libraries so many ages ago, and none are more eloquent of the elaborateness of these forgotten civilizations.

In the course of his excavations at Nineveh in 1850, Assyria Layard came upon some chambers in the south-west palace, the floor of which, as well as of the adjoining rooms, was covered to the depth of a foot with tablets of clay, covered with cuneiform characters, in many cases so small as to require a magnifying glass. These varied in size

from an inch to a foot square. A great number of them were broken, as Layard supposed by the falling in of the roof, but as the late Mr. George Smith thought by having fallen from the upper story, upon which he believed the collection to have been placed. These tablets formed the library of the great monarch Assur-bani-pal—the Sardanapalus of the Greeks—the greatest patron of literature amongst the Assyrians. It is estimated that this library consisted of some ten thousand distinct works and documents, some of the works extending over several tablets. The tablets appear to have been methodically arranged and catalogued, and the library seems to have been thrown open for the general use of the king's subjects.¹ A great portion of this library has already been brought to England and deposited in the British Museum, but it is calculated that there still remain some 20,000 fragments to be gathered up. For further details as to Assyrian libraries, and the still earlier Babylonian libraries from which the Assyrians drew their science and literature, see *BABYLONIA*, vol. iii. p. 191.

Egypt.

Of the libraries of ancient Egypt our knowledge is much less full and precise. It seems to be ascertained that the oldest hieroglyphic writings now extant run some centuries farther back than 2000 B.C. We possess a papyrus manuscript which is assigned to the age of Amenophis I. of the 18th dynasty, perhaps about 1800 B.C., and the fabric is so perfect as to point to a much earlier invention.² With the invention of papyrus came the age of books. The temples were the centres of literary activity, and to each of them were attached professional scribes who occupied a very respectable position. Their function was regarded as a religious one, for the distinction between religion and science had not yet been made. The sacred books of Thoth—forty-two in number—constituted as it were a complete encyclopædia of religion and science. But they did not forbid speculation, or a wider development of the principles contained in them. So there arose a great mass of literature in the shape of exposition and commentary. To such an extent did this increase that at the time of the Greek conquest of Egypt the Thoth literature is said to have amounted to 36,826 books.³ Books were collected not only in the temples but also at the tombs of kings. The most famous of these libraries dates from the 14th century B.C., and was the so-called library of King Osmendias, described by Diodorus Siculus, who relates that it bore an inscription which he renders by the Greek words ΨΥΧΗΣ ΙΑΤΡΕΙΟΝ, "the dispensary of the soul." Osmendias has been identified with the great king Ramses I., and the seat of the library is supposed by Wilkinson to have been the Ramesseum, the magnificent palace temple near Thebes.⁴ Lepsius thinks he has found the tombs of two of the librarians of Osmendias.⁵ According to Eusebius there was also a great collection in a temple at Memphis. A heavy blow was dealt to the old Egyptian literature by the Persian invasion, and many of their books were carried away by the conquerors. They were only delivered from the yoke of Persia to succumb to that of Greece, and henceforward their civilization was dominated by foreign influences. Of the libraries of Greece under the Ptolemies we shall therefore speak a little further on.

Greece.

Of the libraries of ancient Greece we have very little knowledge, and such knowledge as we possess comes to us for the most part from late compilers. Amongst those who are known to have collected books are Ptolemy, Polyarchus of Samos, Euclid the Athenian, Nicocrates of

Cyprus, Euripides and Aristotle (Athenæus, i. 4). At Cnidus there is said to have been a special collection of works upon medicine. Ptolemy is said to have been the first of the Greeks who collected books on a large scale.

Aulus Gellius, indeed, tells us in language perhaps "not well suited to the 6th century A.D.,"⁶ that he was the first to establish a public library. The authority of Aulus Gellius is hardly sufficient to secure credit for the story that this library was carried away into Persia by Xerxes and subsequently restored to the Athenians by Seleucus Nicator. Plato is known to have been a collector, and Xenophon tells us of the library of Euthydemus. The library of Aristotle was bequeathed by him to his disciple Theophrastus, and by Theophrastus to Neleus, who carried it to Scepsis, where it is said to have been concealed underground to avoid the literary cupidity of the kings of Pergamum. Its subsequent fate has given rise to much controversy, but, according to Strabo (xii. pp. 608, 609), it was sold to Apollonius of Teos, who carried it to Athens, where after Apollonius' death it fell a prey to the conspirator Sulla, and was transported by him to Rome. The story told by Athenæus (i. 4) is that the library of Neleus was purchased by Ptolemy Philadelphus. The names of a few other libraries in Greece are barely known to us from inscriptions, of their character and contents we know nothing. If indeed we are to trust Strabo entirely, we must believe that Aristotle was the first person who collected a library, and that he communicated the taste for collecting to the sovereigns of Egypt.

It is at all events certain that the libraries of Alexandria were the most important as they were the most celebrated of the ancient world. Under the enlightened rule of the Ptolemies a society of scholars and men of science was attracted to their capital. It seems pretty certain that Ptolemy Soter had already begun to collect books, but it was in the reign of Ptolemy Philadelphus that the libraries were properly organized and established in separate buildings. Ptolemy Philadelphus sent into every part of Greece and Asia to secure the most valuable works, and no exertions or expense were spared in enriching the collections. Ptolemy Euergetes, his successor, is said to have caused all books brought into Egypt by foreigners to be seized for the benefit of the library, while the owners had to be content with receiving copies of them in exchange. Nor did the Alexandrian scholars exhibit the usual Hellenic exclusiveness, and many of the treasures of Egyptian and even of Hebrew literature were by their means translated into Greek. There were two libraries at Alexandria; the larger, in the Bruchium quarter, was in connexion with the Museum, a sort of academy, while the smaller was placed in the Serapeum. The number of volumes in these libraries was very large, although it is difficult to attain any certainty as to the real numbers amongst the widely varying accounts. According to a scholium of Theophrastus, who appears to draw his information from the authority of Callimachus and Eratosthenes, who had been librarians at Alexandria, there were 42,800 volumes or rolls in the Serapeum and 490,000 in the Bruchium.⁷ This enumeration seems to refer to the librarianship of Callimachus himself under Ptolemy Euergetes. In any case the figures agree tolerably well with those given by Aulus Gellius⁸ (700,000) and Seneca⁹ (400,000). It should be observed that, as the ancient roll or volume usually contained a much smaller quantity of matter than a modern book—so that, e.g., the history of Herodotus might form nine "books" or volumes, and the *Iliad* of Homer twenty-four—these numbers must be dis-

counted for the purposes of comparison with modern collections.¹ The series of the first five librarians at Alexandria appears to be pretty well established as follows—Zenodotus, Callimachus, Eratosthenes, Apollonius, and Aristophanes; and their activity covers a period of about a century.² The first experiments in bibliography appear to have been made in producing catalogues of the Alexandrian libraries. Amongst other lists, two catalogues were prepared by order of Ptolemy Philadelphus, one of the tragedies, the other of the comedies contained in the collections. The *Mouseion* of Callimachus formed a catalogue of all the principal books arranged in 120 classes. When Caesar set fire to the fleet in the harbour of Alexandria, the flames accidentally extended to the larger library of the Bruchium, and it was destroyed.³ Antony endeavoured to repair the loss by presenting to Cleopatra the library from Pergamus. This was very probably placed in the Bruchium, as thus continued to be the literary quarter of Alexandria until the time of Aurelian. Thenceforward the Serapeum became the principal library. The usual statement that from the date of the restoration of the Bruchium under Cleopatra the libraries continued in a flourishing condition until they were destroyed after the conquest of Alexandria by the Saracens in 640 A.D. can hardly be supported. It is very possible that one of the libraries perished when the Bruchium quarter was destroyed by Aurelian, 273 A.D. In 389 or 391 an edict of Theodosius ordered the destruction of the Serapeum, and its books were pillaged by the Christians. When we take into account the disordered condition of the times, and the neglect into which literature and science had fallen, there can be little difficulty in believing that there were but few books left to be destroyed by the soldiers of 'Amr. The familiar anecdote of the caliph's message to his general (vol. i. p. 494) rests mainly upon the evidence of Abulfargius, so that we may be tempted to agree with Gibbon that the report of a stranger who wrote at the end of six hundred years is overbalanced by the silence of earlier and native annalists. It is, however, so far from easy to settle the question that a cloud of names could easily be cited upon either side, while some of the most careful inquirers confess the difficulty of a decision.⁴

779-
as The magnificence and renown of the libraries of the Ptolemies excited the rivalry of the kings of Pergamus, who vied with the Egyptian rulers in their encouragement of literature. Despite the obstacles presented by the embargo placed by the Ptolemies upon the export of papyrus, the library of the Attali attained considerable importance, and, as we have seen, when it was transported to Egypt numbered 300,000 volumes. We learn from a notice in Suidas that in 221 A.C. Antiochus the Great summoned the poet and grammarian Euphorion of Chalcis to be his librarian.

1000. The early Romans were far too warlike and practical a people to devote much attention to literature, and it is not until the last century of the republic that we hear of libraries in Rome. The collections of Carthage, which fell into their hands when Scipio sacked that city (149 A.C.), had no attractions for them; and with the exception of the writings of Mago upon agriculture, which the senate reserved for translation into Latin, they bestowed all the

books upon the kinglets of Africa.⁵ It is in accordance with the military character of the Romans that the first considerable collections of which we hear in Rome were brought there as the spoils of war. The first of these was that brought by Æmilius Paulus from Macedonia after the conquest of Perseus (167 A.C.). The library of the conquered monarch was all that he reserved from the prizes of victory for himself and his sons, who were fond of letters. Next came the library of Apellion the Teian, brought from Athens by Sulla (86 B.C.). This passed at his death into the hands of his son, but of its later history nothing is known. The rich stores of literature brought home by Lucullus from his eastern conquests (about 67 B.C.) were freely thrown open to his friends and to men of letters. Accordingly his library and the neighbouring walks were much resorted to, especially by Greeks. It was now becoming fashionable for rich men to furnish their libraries well, and the fashion prevailed until it became the subject of Seneca's scorn and Lucian's wit. The zeal of Cicero and Atticus in adding to their collections is well known to every reader of the classics. Tyrannius is said to have had 30,000 volumes of his own; and that M. Terentius Varro had large collections we may infer from Cicero's writing to him: "Si hortum in bibliotheca habes, nihil deerit." Not to prolong the list of private collectors, Sereus Sammonicus is said to have left to his pupil the younger Gordian no less than 62,000 volumes. Amongst the numerous projects entertained by Caesar was that of presenting Rome with public libraries, though it is doubtful whether any steps were actually taken towards its execution. The task of collecting and arranging the books was entrusted to Varro. This commission, as well as his own fondness for books, may have led Varro to write the book upon libraries of which a few words only have come down to us, preserved by a grammarian. Varro also appears to have been the first to ornament a library with the statues and busts of learned men, though the idea is sometimes attributed to Asinius Pollio. The greater honour of being the first actually to dedicate a library to the public is said by Pliny and Ovid to have fallen to Pollio, who erected a library in the Atrium Libertatis on Mount Aventine, defraying the cost from the spoils of his Illyrian campaign. The library of Pollio was followed by the public libraries established by Augustus. That emperor, who did so much for the embellishment of the city, erected two libraries, the Octavian and the Palatine. The former was founded (33 A.C.) in honour of his ancestor, and was placed in the Porticus Octaviae, the lower part of which served as a promenade, while the upper part contained the library. The charge of the books was committed to C. Melissus. The other library formed by Augustus was attached to the temple of Apollo on the Palatine hill, and appears from inscriptions to have consisted of two departments, a Greek and a Latin one, which seem to have been separately administered. The charge of the Palatine collections was given to Pompeius Macer, who was succeeded by Julius Hyginus, the grammarian and friend of Ovid. The Octavian library perished in the fire which raged at Rome for three days in the reign of Titus. The Palatine was, at all events in great part, destroyed by fire in the reign of Commodus. The story that its collections were destroyed by order of Pope Gregory the Great in the 6th century is now generally rejected. The successors of Augustus, though they did not equal him in their patronage of learning, maintained the tradition of forming libraries. Tiberius, his immediate successor, established one in his splendid house on the Palatine, to which Gellius refers as the "Tiberian library," and

¹ This view as to the smallness of the ancient book before Callimachus has been pushed perhaps a little too far. See Theodor Birt's ingenious suggestions in *Das antike Buchwesen*, Berlin, 1893, p. 439 ff. Dr. Birt, indeed, agrees that these large numbers must be discounted, but only on the ground of the very considerable number of duplicates in the Alexandrian libraries.

² Reisch, *loc. cit.*, 19.

³ Parthey (*Alexandrinisches Museum*) assigns topographical reasons for doubting this story.

⁴ Some of the authorities have been collected by Parthey, *op. cit.*

⁵ Pliny, *H. N.*, xviii. 5.

Suetonius relates that he caused the writings and images of his favourite Greek poets to be placed in the public libraries. Vespasian established a library in the Temple of Peace erected after the burning of the city under Nero. Domitian restored the libraries which had been destroyed in the same conflagration, procuring books from every quarter, and even sending to Alexandria to have copies made. He is also said to have founded the Capitoline library, though others give the credit to Hadrian. The most famous and important of the imperial libraries, however, was that created by Ulpian Trajanus, known as the Ulpian library, which was first established in the Forum of Trajan, but was afterwards removed to the baths of Diocletian. In this library were deposited by Trajan the "libri iurisi" and "libri elephantini," upon which the senatus consulta and other transactions relating to the emperors were written. The library of Domitian, which had been destroyed by fire in the reign of Commodus, was restored by Gordian, who added to it the books bequeathed to him by Surrentus Summoecus. Altogether in the 4th century there are said to have been twenty-eight public libraries in Rome.

Nor were public libraries confined to Rome. Besides a library at Tiber, which is twice mentioned by Gellius, and was probably founded by Hadrian, the younger Pliny mentions that he had himself dedicated a library to his fellow-townsmen at Comum; and an inscription discovered at Milan proves that he also contributed a large sum to the support of a library there. Hadrian established a library at Athens; and Strabo mentions the library of Smyrna. Gellius also mentions a library at Patra. From one of his references (xix. 5) to the Tiburtine library we may infer that it was not unusual for books to be lent out from these libraries. Considerable care was bestowed by the Romans upon the placing of their libraries. The room or building generally had an eastern aspect. The books or rolls were arranged upon the shelves of presses running round the walls, with additional presses placed in the middle of the room. Thus the library discovered at Herculaneum contained 1756 MSS. placed on shelves running round the room to a height of some 6 feet, with a detached central press. These presses in large libraries were numbered. They were often made of precious woods and richly ornamented, while the room was adorned with portraits and statues.

As the number of libraries in Rome increased, the librarian, who was generally a slave or freedman, became a recognized public functionary. The names of several librarians are preserved to us in inscriptions, including that of C. Hyemenus, who appears to have fulfilled the double function of physician and librarian to Augustus. The general superintendence of the public libraries was committed to a special official. Thus from Nero to Trajan Dionysius, an Alexandrian rhetorician, discharged this function. Under Hadrian it was entrusted to his former tutor C. Julius Vestinus, who afterwards became administrator of the Museum at Alexandria.

When the seat of empire was removed by Constantine to his new capital upon the Bosphorus, the emperor established a collection there, in which Christian literature was probably admitted for the first time into an imperial library. Diligent search was made after the Christian books which had been doomed to destruction by Diocletian. Even at the death of Constantine, however, the number of books which had been brought together amounted only to 6900. The smallness of the number, it has been suggested, seems to show that Constantine's library was mainly intended as a repository of Christian literature. However this may be, the collection was greatly enlarged by some of Constantine's successors, especially by Julian and Theodosius, at whose

death it is said to have increased to 100,000 volumes. Julian, himself a close student and voluminous writer, though he did his best to discourage learning among the Christians, and to destroy their libraries, not only augmented the library at Constantinople, but founded others, including one at Nisibis, which was soon afterwards destroyed by fire. From the Theodosian code we learn that in the time of that emperor a staff of seven copyists was attached to the library at Constantinople under the direction of the librarian. The library was burnt under the emperor Zeno in 477, but was again restored.

Meanwhile, as Christianity made its way and a distinctively Christian literature grew up, the institution of libraries became part of the organization of the church. When the church of Jerusalem was founded in the 3d century a library was added to it, and it became the rule to attach to every church a collection of the books necessary for the inculcation of Christian doctrine. The largest of these libraries, that founded by Pamphilus at Caesarea, and said to have been increased by Eusebius, the historian of the church, to 30,000 volumes, is frequently mentioned by St Jerome. St Augustine bequeathed his collection to the library of the church at Hippo, which was fortunate enough to escape destruction at the hands of the Vandals.

The removal of the capital to Byzantium was in its result a serious blow to literature. Henceforward the science and learning of the East and West were divorced. The libraries of Rome ceased to collect the writings of the Greeks, while the Greek libraries had never cared much to collect Latin literature. The influence of the church became increasingly hostile to the study of pagan letters. The repeated irruptions of the barbarians soon swept the old learning and libraries alike from the soil of Italy. With the close of the Western empire in 476 the ancient history of libraries may be said to cease.

MEDIEVAL PERIOD.

During the first few centuries after the fall of the Western empire, literary activity at Constantinople had fallen to its lowest ebb. In the West, amidst the general neglect of learning and literature, the collecting of books, though not wholly forgotten, was cared for by few. Sidonius Apollinaris tells us of the libraries of several private collectors in Gaul. Publius Consentius possessed a library at his villa near Narbonne which was due to the labour of three generations. The most notable of these appears to have been the prefect Tonantius Ferreolus, who had formed in his villa of Prusiana, near Nîmes, a collection which his friend playfully compares to that of Alexandria. The Goths, who had been introduced to the Scriptures in their own language by Ulfilas in the 4th century, began to pay some attention to Latin literature. Cassiodorus, the favourite minister of Theodoric, was a collector as well as an author, and on giving up the care of government retired to a monastery which he founded in Calabria, where he employed his monks in the transcription of books.

Henceforward the charge of books as well as of education fell more and more exclusively into the hands of the church. While the old schools of the rhetoricians died out new monasteries arose everywhere. Knowledge was no longer pursued for its own sake, but became subsidiary to religious and theological teaching. The prescription of the old classical literature, which is symbolized in the fable of the destruction of the Palatine library by Gregory the Great, was only too effectual. The Gregorian tradition of opposition to pagan learning long continued to dominate the literary pursuits of the monastic orders and the labours of the scriptorium.

During the 6th and 7th centuries the learning which had been driven from the Continent took refuge in the British Islands, where it was removed from the political disturbances of the mainland. In the Irish monasteries during this period there appear to have been many books, and the Venerable Bede was superior to any scholar of his age. Theodore of Tarsus brought a considerable number of books to Canterbury from Rome in the 7th century, including several Greek authors. The library of York, which was founded by Archbishop Egbert, was almost more famous than that of Canterbury. The verses are well known in which Alcuin describes the extensive library under his charge, and the long list of authors whom he enumerates is superior to that of any other library possessed by either England or France in the 12th century, when it was unhappily burnt. The incursions of the Northmen in the 9th and 10th centuries had been fatal to the monastic libraries on both sides of the channel. It was from York that Alcuin came to Charlemagne to superintend the school attached to his palace; and it was doubtless inspired by Alcuin that Charles issued the memorable document which enjoined that in the bishoprics and monasteries which had been founded in 774, and which all through the Middle Ages stood in great respect. Lupus Servatus, a pupil of Hrabanus Maurus at Fulda, and afterwards abbot of Ferrières, was a devoted student of the classics and a great collector of books. His correspondence illustrates the difficulties which then attended the study of literature through the paucity and dearth of books, the declining care for learning and the increasing troubles of the time. Nor were private collections of books altogether wanting during the period in which Charlemagne and his successors laboured to restore the lost traditions of liberal education and literature. Pepin le Bref had indeed met with scarcely response to the request for books which he addressed to the pontiff Paul I. Charlemagne, however, collected a considerable number of choice books for his private use in two places. Although these collections were dispersed at his death, his son Louis formed a library which continued to exist under Charles the Bald. About the same time Eberard, count of Friuli, formed a considerable collection which he bequeathed to a monastery. But the greatest private collector of the Middle Ages was doubtless Gerbert, Pope Sylvester II, who showed the truest zeal and spent large sums in collecting books, not only in Rome and Italy, but from Germany, Belgium, and even from Spain.

The hopes of a revival of secular literature fell with the decline of the schools established by Charles and his successors. The knowledge of letters remained the prerogative of the church, and for the next four or five centuries the collecting and multiplication of books were almost entirely confined to the monasteries. Several of the greater orders made these an express duty; this was especially the case with the Benedictines. It was the first care of St. Benedict, we are told, that in each newly founded monastery there should be a library, "at vult curia quædam illustrium auctorum." Monte Cassino became the starting point of a long line of institutions which were destined to be the centres of religion and of literature. It must indeed be remembered that literature in the sense of St. Benedict meant Biblical and theological works, the lives of the saints and martyrs, and the lives and writings of

the fathers. Of the reformed Benedictine orders the Carthusians and the Cistercians were those most devoted to literary pursuits. The abbots of Fleury, of Malm, and of St. Gall were remarkable for the splendour of their libraries. In a later age the labours of the congregation of St. Maur form one of the most striking chapters in the history of learning. The Augustinians and the Dominicans rank next to the Benedictines in their care for literature. The libraries of St. Geneviève and St. Victor, belonging to the former, were amongst the largest of the monastic collections. Although their poverty might seem to put them at a disadvantage as collectors, the mendicant orders cultivated literature with much assiduity, and were closely connected with the intellectual movement to which the universities owed their rise. In England Richard of Bury presses them for their extraordinary diligence in collecting books. Sir Richard Whittington built a large library for the Grey Friars in London, and they possessed considerable libraries at Oxford.

It would be impossible to attempt here an account of all the libraries established by the monastic orders. We must be content to enumerate a few of the most eminent.

In Italy Monte Cassino is a striking example of the dangers and vicissitudes to which monastic collections were exposed. Ruined by the Lombards in the 6th century, the monastery was rebuilt and a library established to fall a prey to Saracens and to fire in the 9th. The collection then reformed survived many other chances and changes, and still exists. It affords a conspicuous example of monastic industry in the transcription not only of theological but also of classical works. The library of Bobbio was famous for its palimpsests. The collection, of which a catalogue of the 10th century is given by Muratori,¹ was finally transferred to the Ambrosian library at Milan. Of the library of Pomposio, near Ravenna, Montauson has printed a catalogue dating from the 11th century.

Of the monastic libraries of France the principal were those of Fleury, of Cluny, of St. Riquier, and of Corbie. At Fleury Abbot Macharius in 1146 imposed a contribution for library purposes upon the officers of the community and its dependences, an example which was followed elsewhere. After many vicissitudes, its MSS., numbering 233, were deposited in 1753 in the town library of Orléans. The library of St. Riquier in the time of Louis the Pious contained 256 MSS., with over 500 works.² Of the collection at Corbie in Picardy we have also catalogues dating from the 12th and from the 17th centuries. Corbie was famous for the industry of its transcribers, and appears to have stood in active literary intercourse with other monasteries. In 1638, 490 of its choicest manuscripts were removed to St. Germain-des-Prés. The remainder were removed after 1794, partly to the national library at Paris, partly to the town library of Amiens.³

The chief monastic libraries of Germany were at Fulda, Corvey, Reichenau, and Speinheim. The library at Fulda owed much to Charlemagne and to its abbot Hrabanus Maurus. Under Abbot Sturmus four hundred monks were hired as copyists. In 1561 the collection numbered 774 volumes. The library of Corvey on the Weser, after being despoiled of some of its treasures in the Reformation age, was presented to the university of Marburg in 1811. It then contained 109 volumes, with 400 or 500 titles. The library of Reichenau, of which several catalogues are extant, fell a prey to fire and neglect, and its ruin was consummated by the Thirty Years' War. The library

² *Diatribæ Bibliocæ*, chap. xxii.

³ Catalogue printed in Edwards, *Memoirs of Libraries*, i. 397-401.

of Sponheim owes its great renown to John Trithemius, who was abbot at the close of the 15th century. He found it reduced to 10 volumes, and left it with upwards of 2000 at his retirement. The library at St Gall, formed as early as 816 by Goxbert, its second abbot, still exists.

England. In England the principal collections were those of Canterbury, York, Wearmouth, Whitby, Glastonbury, Croyland, Peterborough, and Durham. Of the library of the monastery of Christ Church, Canterbury, originally founded by Augustine and Theodore, and restored by Lanfranc and Anselm, a catalogue has been preserved dating from the 13th or 14th century, and containing 698 volumes, with about 3000 works. Bennet Biscop, the first abbot of Wearmouth, made five journeys to Rome, and on each occasion returned with a store of books for the library. It was destroyed by the Danes about 867. Of the library at Whitby there is a catalogue dating from the 12th century. The catalogue of Glastonbury has also been printed.¹ When the library of Croyland perished by fire in 1091 it contained about 700 volumes. The library at Peterborough was also rich; from a catalogue of about the end of the 14th century it had 344 volumes, with nearly 1700 titles. The catalogues of the library at the monastery of Durham have been printed by the Surtees Society, and form an interesting series.

These catalogues with many others² afford abundant evidence of the limited character of the monkish collections, whether we look at the number of their volumes or at the nature of their contents. We must remember that the beliefs and discipline imposed upon the monk hardly allowed of his caring for literature for its own sake; we must also remember that the transcription of manuscripts so industriously pursued in the monasteries was a mechanical employment. The scriptoria were manufactories of books and not centres of learning. Indeed the very pains bestowed upon carefulness and neatness of transcription, and especially upon the illustrating and ornamenting of the more beautiful manuscripts, were little calculated to divert the attention of the monks from the vehicle to the thought which it expressed. The pride taken by so many communities in the richness and splendour of their libraries was often doubtless the pride of the collector and not of the scholar. That in spite of the labours of so many transcribers the costliness and scarcity of books remained so great may have been partly, but cannot have been wholly, due to the scarcity of writing materials. It may be suspected that indolence and carelessness were the rule in most monasteries, and that but few of the monks keenly realized the whole force of the sentiment expressed by one of their number in the 12th century—"Cianstrum sine armario quasi castrum sine armamento." Nevertheless it must be admitted that to the labours of the monkish transcribers we are indebted for the preservation of Latin literature.

Arabians. The first conquests of the Arabians, as we have already seen, threatened hostility to literature. But, as soon as their conquests were secured, the caliphs became the patrons of learning and science. Greek manuscripts were eagerly sought for and translated into Arabic, and colleges and libraries everywhere arose. Baghdad in the East and Cordova in the West became the seats of a rich development of letters and science during the ages when the civilisation

of Europe was most obscured. Cairo and Tripoli were also distinguished for their libraries. The royal library of the Fatimies in Africa is said to have numbered 100,000 manuscripts, while that collected by the Omayyads of Spain is reported to have contained six times as many. It is said that there were no less than seventy libraries opened in the cities of Andalusia. Whether these figures be exaggerated or not—and they are much below those given by some Arabian writers, which are undoubtedly so—it is certain that the libraries of the Arabians and the Moors of Spain offer a very remarkable contrast to those of the Christian nations during the same period.³

The literary and scientific activity of the Arabians appears to have been the cause of a revival of letters amongst the Greeks of the Byzantine empire in the 9th century. Under Leo the Philosopher and Constantine Porphyrogenitus the libraries of Constantinople awoke into renewed life. The compilations of such writers as Stobaeus, Photius, and Suidas, as well as the labours of innumerable critics and commentators, bear witness to the activity, if not to the lofty character of the pursuits, of the Byzantine scholars. The labours of transcription were industriously pursued in the libraries and in the monasteries of Mount Athos and the Aegean, and it was from these quarters that the restorers of learning brought into Italy so many Greek *Recens.* manuscripts. In this way many of the treasures of ancient literature had been already conveyed to the West before the fate which overtook the libraries of Constantinople on the fall of the city in 1453.

Meanwhile in the West, with the reviving interest in literature which already marks the 14th century, we find arising outside the monasteries a taste for collecting books. St Louis of France and his successors had formed small collections, none of which survived its possessor. It was reserved for Charles V. to form a considerable library which he intended to be permanent. In 1375 he had amassed 910 volumes, and had a catalogue of them prepared, from which we see that it included a good deal of the new literature. In our own country Guy, earl of Warwick, formed a curious collection of French romances, which he bequeathed toordesley Abbey on his death in 1315. Richard d'Angervyle of Bury, the author of the *Philobiblon*, amassed a noble collection of books, and had special opportunities of doing so as Edward III.'s chancellor and ambassador. He founded Durham College at Oxford, and equipped it with a library a hundred years before Humphrey, duke of Gloucester, made his benefaction of books to the university. The taste for secular literature, and the enthusiasm for the ancient classics, gave a fresh direction to the researches of collectors. A disposition to encourage literature began to show itself amongst the great. This was most notable amongst the Italian princes. Cosimo de' Medici formed a library at Venice while living there in exile in 1433, and on his return to Florence laid the foundation of the great Medicean library. The honour of establishing the first modern public library in Italy had been already secured by Niccolò Niccoli, who left his library of over 800 volumes for the use of the public on his death in 1436. Frederick, duke of Urbino, collected all the writings in Greek and Latin which he could procure, and we have an interesting account of his collection written by his first librarian, Vespasiano. The ardour for classical studies led to those active researches for the Latin writers who were buried in the monastic libraries which are especially identified with the name of Poggio. For some time before the fall of that capital, the perilous state

¹ By Heame in his edition of John of Glastonbury.

² Many such catalogues may be found in the collections of D'Achery, Martene and Durand, and Pex, and in the bibliographical periodicals of Nazarian and Fethallah. The Rev. Joseph Hunter has collected some particulars as to the contents of the English monastic libraries, and Mr Edwards has printed a list of the catalogues known to exist (*Libraries and Founders of Libraries*, 1865, pp. 448-54). There are said to be over six hundred such catalogues in the Royal Library at Munich.

³ Among the Arabs, however, as among the Christians, theological bigotry did not always approve of non-theological literature, and the great library of Cordova was sacrificed by Almanzor to his reputation

of the Eastern empire had driven many Greek scholars from Constantinople into western Europe, where they had directed the studies and formed the taste of the zealous students of the Greek language and literature. The enthusiasm of the Italian princes extended itself beyond the Alps. Matthias Corvinus, king of Hungary, amassed a collection of splendidly executed and magnificently bound manuscripts, which at his death are said to have reached the almost incredible number of 50,000 volumes. The library was not destined long to survive its founder. There is reason to believe that it had been very seriously despoiled even before it perished at the hands of the Turks on the fall of Buda in 1527. A few of its treasures are still preserved in some of the libraries of Europe. While these munificent patrons of learning were thus taking pains to recover and multiply the treasures of ancient literature by the patient labour of transcribers and calligraphers, an art was being elaborated which was destined to revolutionize the whole condition of literature and libraries. With the invention of printing, so happily coinciding with the revival of true learning and sound science, the modern history of libraries may be said to begin.

MODERN LIBRARIES.

These are most conveniently described in geographical order, and a general survey on this method will be found in the tables at the end of this article. The following sketch supplies additional details.

The United Kingdom.

^{British Museum.} The British Museum ranks in importance before all the great libraries of the world, with the single exception of the Bibliothèque Nationale at Paris, and far exceeds the latter institution in the systematic arrangement and accessibility of its contents. Recent changes have somewhat limited its former universality of character, but it still remains the grand national repository of literature and archaeology. The library consists of over 1,550,000 printed volumes and 50,000 manuscripts. This extraordinary opulence is principally due to the enlightened energy of the late Sir Antonio Panizzi. The number of volumes in the printed book department, when he took the keepership in 1837, was only 240,000; and during the nineteen years he held that office about 400,000 were added, mostly by purchase, under his advice and direction. It was Panizzi likewise who first seriously set to work to see that the national library reaped all the benefits bestowed upon it by the Copyright Act.

The foundation of the British Museum dates from 1753, when effect was given to the bequest (in exchange for £30,000 to be paid to his executors) by Sir Hans Sloane, of his books, manuscripts, curiosities, &c., to be held by trustees for the use of the nation. A bill was passed through parliament for the purchase of the Sloane collections and of the Harleyan MSS., costing £10,000. To these, with the Cottonian MSS., acquired by the country in 1700, was added by George II., in 1757, the royal library of the former kings of England, coupled with the privilege, which that library had for many years enjoyed, of obtaining a copy of every publication entered at Stationers' Hall. This addition was of the highest importance, as it enriched the museum with the old collections of Archbishop Cranmer, Henry prince of Wales, and other patrons of literature, while the transfer of the privilege with regard to the acquisition of new books, a right which has been maintained by successive Copyright Acts, secured a large and continuous augmentation, the yearly average of which has now reached 8000 or 9000 volumes. A lottery having

been authorized to defray the expenses of purchases, as well as for providing suitable accommodation, the museum and library were established in Montagu House, and opened to the public 16th January 1759. In 1763 George III. presented the well-known Thomason collection (in 2320 volumes) of books and pamphlets issued in England between 1640 and 1662, embracing all the controversial literature which appeared during that period. The Rev. C. M. Cracherode, one of the trustees, bequeathed his collection of choice books in 1798, and in 1820 Sir Joseph Banks left to the nation his important library of 16,000 volumes. Many other libraries have since then been incorporated in the museum, the most valuable being George III.'s royal collection (18,000 volumes of tracts, and 65,259 volumes of printed books, including many of the utmost rarity, which had cost the king about £130,000), which was presented (for a pecuniary consideration, it has been said) by George IV. in 1823, and that of the Right Honourable Thomas Grenville (20,240 volumes of rare books, all in fine condition and binding), which was acquired under bequest in 1846. The Cracherode, Banksian, King's, and Grenville libraries are still preserved as separate collections. Other libraries of minor note have also been absorbed in a similar way, while, at least since the time of Panizzi, no opportunity has been neglected of making useful purchases at all the British and Continental book auctions.

The collection of English books is far from approaching completeness, but, apart from the enormous number of volumes, the library contains an extraordinary quantity of rarities. Few libraries in the United States equal either in number or value the American books in the museum. The collection of Slavonic literature, due to the initiative of the late Mr Watts, is a remarkable feature; after that of the St Petersburg Imperial Library it is believed to be the largest in existence. Indeed, in cosmopolitan interest the museum is without a rival in the world, possessing as it does the best Hungarian collection out of that country, the best Dutch library out of Holland, and in short the best library in any European language out of the territory in which the language is vernacular. The Hebrew books number over 12,000, the Chinese nearly 27,000, and the printed books in other Oriental languages about 13,000 volumes. Periodical literature has not been forgotten, and the series of newspapers is of great extent and interest. Great pains are taken by the authorities to obtain the copies of the newspapers published in the United Kingdom to which they are entitled by the provisions of the Copyright Act, and upwards of 1900 are annually collected, filed, and bound. Under the English Copyright Act there were received, in 1881, not counting single pieces, such as broadsides, songs, &c., 8567 volumes and pamphlets, and 31,792 parts of volumes, and through the international copyright treaties 941 volumes and 433 parts.

The department of MSS. is at least equal in importance to that of the printed books. The collection of MSS. in European languages ranges from the 2d century before Christ down to our own times, and includes the *ALEXANDRIAN MS. (g.a.)*. The old historical chronicles of England, the charters of the Anglo-Saxon kings, and the celebrated series of Arthurian romances are well represented; and care has been taken to acquire on every available opportunity the unprinted works of English writers. The famous collections of MSS. made by Sir Robert Cotton, and Harley and of Oxford, have already been mentioned, and from these and other sources the museum has become rich in early Anglo-Saxon and Latin codices, some of them exhibiting marvels of skill in calligraphy and ornamentation, such as the charters of King Edgar and Henry I. to Hyde Abbey, which are written in gold letters, others interesting for different reasons, such as the book of Durham, in Latin and Anglo-

Saxon, reputed to have been Bede's own copy. The Burney collection of classical MSS. furnished important additions, so that from this source and from the collection of Arundel MSS. (transferred from the Royal Society in 1831), the museum can boast of an early copy of the *Iliad*, and one of the earliest known codices of the *Odyssey*. There is likewise an extensive series of ancient Irish texts, with many modern transcripts, the Bridgewater MSS. on French history, and Lord Guilford's similar collection to illustrate the history of Italy. Special references may be made to the celebrated Bedford Missal, illuminated by the duke of Bedford, regent of France, and to Henry VI.'s copy of Hardyng's chronicle. The Oriental collection is also extremely rich and ample, including the library formed by Mr Rich (consul at Baghdad in the early part of this century), and a vast quantity of Arabic, Persian, and Turkish MSS.; the Chambers collection of Sanskrit MSS.; several other collections of Indian MSS.; and a copious library of Hebrew MSS. (including that of the great scholar Michaelis, and codices of great age, recently brought from Yemen). The collection of Syriac MSS., embracing the relics of the famous library of the convent of St Mary Deipara in the Nitrian desert, formed by the abbot Moses of Nisibis, in the 10th century, is the most important in existence; of the large store of Abyssinian volumes many were amassed after the campaign against King Theodore. The number of genealogical rolls and documents relating to the local and family history of Great Britain is very large. Altogether there are now over 50,000 MSS. (of which 8500 are Oriental), besides 45,000 charters and rolls.

The musical works comprise upwards of 11,000 volumes of vocal and nearly 6000 volumes of instrumental music, the number of separate pieces amounting to more than 70,000. The catalogue is in manuscript. The collection of maps, charts, plans, and topographical drawings is also a remarkable one. The maps are nearly 116,000 in number. Letter A of a printed catalogue of the maps is already in type.

The name of Furness is inseparably connected with his circular reading-room, opened in 1867. This is encompassed by the new library, with alcove-space for a million and a half volumes. The presses inside the reading-room, arranged in three tiers, contain upwards of 80,000 volumes, those on the ground floor (80,000) being books of reference to which readers have unlimited access. The comfortable accommodation for readers is briefly described below. Perhaps not the least convenient arrangement here is the presence of the superintendent, whose duty it is to help readers in their difficulties; the varied qualifications of the present holder of the office are well known. The electric light has been successfully used until 8 o'clock P.M. though the darker months from the earlier part of October. In order to enjoy the privilege of reading at the British Museum, the applicant (who must be over twenty-one years of age) must obtain a renewable ticket of admission through a recommendation from a householder addressed to the principal librarian. Formerly no person was admitted until the ticket had been presented at the entrance, but lately this rule has been considerably relaxed. During 1881 the number of readers was 198,842. In spite of the hostile criticism to which it has sometimes been subjected, it cannot be denied that the general catalogue of the printed books (which now runs to upwards of 2000 volumes in manuscript) is a marvellous work executed in a praiseworthy manner. Some slight notion of the extent of the catalogue may be derived from the fact that it contains the works of over 2400 authors of the name of Smith. But the rapidly increasing size of the catalogue has impelled the trustees to resort to print in order to diminish the bulk. Since 1880 the titles of all accessions have been printed, and as it becomes necessary to break the manuscript volumes, the titles contained in them are also printed, in course of time, therefore, the whole of the titles will have been put into type. The sheets are published at regular intervals, and can be purchased. It is proposed to issue separately headings of special interest, whether of subjects or of authors, e.g., Shakespeare, Bible, Liturgies, &c. Considerable progress has been made in the preparation for the press of a catalogue of English books printed before the year 1640.

The printed catalogues of books commence with one published in 2 vols. folio, 1787, followed by that of 1818-19 in 7 vols. 8vo; the next is that of the library of George III. in 2 vols. folio with

2 vols. 8vo, 1884, describing the geographical and topographical collections; and then the *Bibliotheca Grenvilliana*, 1845-74, 4 vols. 8vo. The first vol. (letter A) of a general catalogue appeared in 1841 in a folio volume which has never been added to. The octavo catalogue of the Hebrew books came out in 1867; that of the Sanskrit and Pali literature is in 4to, 1878, and the Chinese catalogue is also in 4to, 1877. There are also printed lists of the books of reference (1871) and bibliographies (1881) in the reading-room. Private enterprise has done a great deal towards cataloguing the American books (by Mr H. Stevens, 4 vols. 8vo), and the British topographical literature has recently been the subject of a similar publication by Mr J. P. Anderson, 8vo, 1881.

The printed catalogues of the MSS. are—that of the old Royal Library, 1794, 4to, the Sloane and others hitherto undescribed, 1782, 2 vols. 4to, the Cottonian, 1802, folio; the Harleian, 1808, 4 vols. folio, the Hargrave, 1813, 4to; the Lansdowne, 1813, folio; the Arundel, 1840, folio; the Burney, 1840, folio; the Oriental (Arabic and Ethiopic), 6 pts., folio, 1858-71; the Syriac, 1870-73, 3 pts., 4to, the Ethiopic, 1877, 4to, the Persian, 1879-80, 2 vols. 4to, and the Spanish, 1875-80, 3 vols. 8vo. There are also catalogues of the Greek and Egyptian papyri, 1859-48, 5 pts., folio. The additional MSS. from 1831-75 are described in 10 vols. 8vo, 1856-77, with indexes (1758-1835) in folio and (1864-76) in 8vo. A catalogue of the MS. museum was produced in 1842, 8vo; and one of the MS. maps in 1844, 2 vols. 8vo.

The binding is done upon the premises, and the sum expended each year is £2000. The average sum annually spent upon the purchase of books is about £10,000, and upon MSS. £2500. Since the catalogue ceased to be transcribed £5000 is annually spent on printing.

London is very badly off as regards public libraries, and other the largest general collection which is available without any tedious preliminary forms is that of the corporation of the city of London at the Guildhall. A library was established here by Sir Richard Whittington between 1421-26, and several notices in the civic records show how well in those times the citizens cared for their books. But it did not remain without accident; in 1522 the Lord Protector Somerset carried off three cart-loads of books, and during the great fire of 1666 the remainder was destroyed together with the library buildings. Nothing was done to repair the loss until 1824, when a committee was appointed, and rooms set apart for library purposes. In 1840 a catalogue of 10,000 volumes was printed, and in 1859 a second was prepared of 40,000 volumes. In consequence of the large and increasing number of the readers, the present fine building was commenced about ten years later, and, after having cost £90,000, was opened in 1873 as a free public library. There are now upwards of 80,000 printed volumes and 300 MSS. The contents are of a general character, and include a special collection of books about London, the Solomonian Hebrew and rabbinical library, and the libraries of the Clockmakers' Company and the old Dutch church in Austin Friars. The only rate-supported library in the metropolis is that of the united parishes of St Margaret and St John at Westminster (13,527 volumes), founded in 1837, principally by the influence of the late Lord Hathley, with a small branch at Knightsbridge. The Notting Hill Free Public Library (5000 volumes) is supported by Mr James Heywood, and the Bethnal Green Free Library and South London Free Library by voluntary subscriptions.

Of libraries of a more special character, those principally devoted to theology have perhaps the first claim to notice. The archiepiscopal library at Lambeth was founded in 1610 by Archbishop Bancroft, and has been enriched by the gifts of Laud, Tenison, Manners Sutton, and others of his successors; it is now lodged in the noble hall built by Juxon. The treasures consist of the illuminated MSS., and a rich store of early printed books; of the latter two catalogues have been issued by S.R. Maitland. The MSS. are described in H. J. Todd's catalogue, 1812. Stion College is a guild of the parochial clergy of the city and suburbs of London, and the library was founded in 1629 for their use; however, many also read (but not borrow) the

Of libraries of a more special character, those principally devoted to theology have perhaps the first claim to notice. The archiepiscopal library at Lambeth was founded in 1610 by Archbishop Bancroft, and has been enriched by the gifts of Laud, Tenison, Manners Sutton, and others of his successors; it is now lodged in the noble hall built by Juxon. The treasures consist of the illuminated MSS., and a rich store of early printed books; of the latter two catalogues have been issued by S.R. Maitland. The MSS. are described in H. J. Todd's catalogue, 1812. Stion College is a guild of the parochial clergy of the city and suburbs of London, and the library was founded in 1629 for their use; however, many also read (but not borrow) the

books when recommended by some benefited metropolitan clergyman. The library is especially rich in liturgies, Port-Royal authors, pamphlets, &c. The copyright privilege was commuted in 1835 for an annual sum of £363, 16s. 2d. The present building was erected immediately after the great fire. The chamber in the old cloisters, in which the library of the dean and chapter of Westminster is preserved, is well known from the charming description by Washington Irving in his *Sketch Book*. There are about 11,000 volumes, mostly of old theology and history, including many rare Bibles and other valuable books. The library of the dean and chapter of St Paul's was founded in very early times, and now numbers some 8700 volumes, mainly theological, besides over 10,300 pamphlets, with a good collection of early Bibles and Testaments, Paul's Cross Sermons, and works connected with the cathedral. Dr Williams's library was founded by the will of an eminent Presbyterian divine of that name; it was opened in 1729. The books (30,000 printed volumes and 1000 MSS.) are housed in a new building, completed in 1873. Theology of all schools of opinion is represented, and there are special collections of theosophical books and MSS., the works of Boehme, Law, and other mystical writers. The MSS. include the original minutes of the Westminster Assembly, letters and treatises of Richard Baxter, &c. The British and Foreign Bible Society has a remarkable collection of Bibles and Biblical literature, of which a printed catalogue was published in 1855. Perhaps the best library of Catholic theology in London is that of the Oratory at South Kensington, established in 1849.

Of the law libraries, that at Lincoln's Inn is the oldest and the largest. It dates from 1497, when John Netherleske, a member of the society, made a bequest of forty marks, part of which was to be devoted to the building of a library for the benefit of the students of the laws of England. A catalogue of the printed books was published in 1859, and the MSS. were catalogued by the Rev. Joseph Hunter in 1837. The library of the Inner Temple is known to have existed in 1540. In the middle of the 17th century it received a considerable benefaction from William Petyt, the well-known keeper of the Tower records. There are now about 36,000 volumes, including the pamphlets collected by John Adolphus for his *History of England*, books on crime and prisons brought together by Mr Crawford, and a selection of works on jurisprudence made by John Austin. A library in connexion with the Middle Temple was in existence during the reign of Henry VIII., but the date usually assigned to its foundation is 1641, when Robert Ashley left his books to the inn of which he had been a member. Gray's Inn Library was perhaps established before 1555. In 1669 was made the first catalogue of the books, and the next, still extant, in 1689. The Incorporated Law Society (1831) has a good law and general library (30,000 volumes), including the best collection of private Acts of Parliament in England, and a large number of pamphlets relating to Anglo-Catholic controversies brought together by the late Rev Joseph Mendham. The catalogue was printed in 1869.

The collegiate library at Dulwich dates from 1619, and a list of its earliest accessions, in the handwriting of the founder, may still be seen. There are now about 7000 volumes of miscellaneous works of the 17th and 18th centuries, with a few rare books. A catalogue of them was printed in 1880; and one describing the MSS. (567) and the muniments (606) was issued during the succeeding year. The last two classes are very important, and include the well-known "Alleyne Papers" and the theatrical diary of Philip Henslow. Soon after the foundation of the University of London in 1837, an endeavour was made to provide a library, but it has had to look to gifts rather

than to purchases for its accessions. In 1871 the university obtained, in this manner, the library of the historian Grote, and in the same year Lord Overstone purchased and presented the mathematical collection of De Morgan. A catalogue was printed in 1875. The books at University College (1828) are much more numerous, and here also a considerable proportion are donations, including the Morrison Chinese library of 10,000 volumes, the Daulby-Roscoe Icelandic books, the Graves mathematical and physical library, and the Barlow Dante bequest. A printed catalogue of the greater portion was brought out in 1879. The library at King's College includes a collection of works on Eastern subjects bequeathed by Dr Marsden, as well as the scientific books formerly belonging to Sir Charles Wheatstone. The medical library is distinct. The educational library at the South Kensington Museum numbers about 42,200 volumes, and may be consulted by teachers and students of the departmental schools, and by other persons on the same terms as the art library mentioned below. The ninth edition of the catalogue appeared in 1876.

The library of the Patent Office is the largest scientific and technical collection, indeed the only one which is readily open to the public. There are at present 80,000 volumes, including a very extensive series of the transactions and journals of learned bodies. A catalogue is now in the press. Transactions and proceedings of societies, with scientific periodicals, compose almost the whole library of the Royal Society, which extends to about 40,000 volumes. The diarist Evelyn induced the seventh duke of Norfolk to present to the Society the Arundel library, part of which had formerly belonged to Matthias Corvinus. The MSS., however, were sold to the British Museum in 1831 for £3559, and a quantity of rare printed books have also been disposed of. Scientific inquirers are freely admitted to the Museum of Practical Geology in Jermyn Street, where there are over 30,000 volumes on geology, mineralogy, mining, and metallurgy, including the former collections of De la Beche and Murchison. A printed catalogue was issued in 1878. For the libraries of other scientific institutions see the tables.

Medical and surgical libraries are attached to all the chief hospitals and medical societies (see the tables).

For the fine arts there is the National Art Library (1852) at the South Kensington Museum, which is now an excellent collection of 56,000 volumes, 66,000 photographs, 25,000 drawings, and 80,000 prints. Art students are admitted free, as are ordinary visitors on Museum pay days; otherwise a charge of 6d. per week is made to the latter. The library of the Royal Academy of Arts, after its journey from Somerset House to Trafalgar Square, has been lodged in the old ball-room of Burlington House since 1875. At the National Gallery is preserved for official use the library (3500 volumes) formerly belonging to Sir C. L. Eastlake, P.R.A., which is particularly rich in catalogues and descriptions of picture galleries. The Royal Institution of British Architects (1834) possesses over 6500 volumes on architectural and allied subjects, including an almost complete collection of editions of Vitruvius. The library of the Royal Academy of Music (1822) is almost exclusively musical, and, although numbering less than 1000 volumes, contains many rare and interesting works. The library of the Sacred Harmonic Society is said to be one of the best arranged and most valuable musical collections in England. A third edition of the printed catalogue appeared in 1872, when the library contained 4851 volumes.¹

¹ For a very complete account of the chief public and private musical collections both at home and abroad, see the article "Musical Libraries," in Grove's *Dictionary of Music*, v. 417.

The best library of archaeology and kindred subjects is that of the Society of Antiquaries, consisting of nearly 20,000 printed volumes and 500 MSS. It is rich in early printed books, topography, heraldry, and numismatics, and includes a curious collection of books on pageants presented by Mr Fairholt, and the remarkable assemblage of lexicographical works formerly belonging to the late Albert Way, given by his widow. There is a good muster of heraldic works at the Herald's College, and the library of Sir John Soane (15,000 volumes) is still preserved in the museum at his house in Lincoln's Inn Fields. The printed catalogue (1878) shows that it is a fairly good collection of books on architecture and antiquities.

Among subscription libraries, the London Library stands first in order of importance. It was founded in 1841 as a lending library for the use of scholars, and Dean Milman, Sir G. C. Lewis, Mr Gladstone, Thomas Carlyle, Henry Hallam, and other eminent men took part in its formation. By means of a moderate subscription, funds were raised for the purchase of books on general subjects, which now amount to about 90,000 volumes. The latest catalogue was printed in 1875, with a supplement in 1881. The London Institution (1808) is a proprietary library to which proprietor's nominees and yearly subscribers also have admission. For reference purposes reader's tickets are very liberally granted to other persons. The books now number about 70,000 volumes in general literature; the departments of history and topography are especially rich, and the number is rapidly growing. A complete catalogue was published in 1837-43; almost the whole collection, including reference and circulating libraries very minutely classified, is contained in one room. Porson filled the position of librarian here at the close of his life, but he proved no better a librarian than did Casanbon before him at Paris. The library of the Royal Institution of Great Britain was founded in 1803 by the subscriptions of the members, amounting, in 1806, to £3000. There are now 40,000 volumes in scientific and general literature; they are not lent out. There is an interesting series of 56 volumes of MS. correspondence relating to the American war.

The libraries of the two branches of the legislature may be named with those of the great public offices. The Foreign Office library contains about 70,000 volumes, including the old library of the Board of Trade (20,000 volumes); history, geography, and law are well represented, and the department of treaties and diplomacy is of course very complete. The India Office library was formed by a vote of the court of directors of the East India Company in 1801. The services in India were also invited to aid in the creation of an institution which should become a permanent repository of Oriental lore, and many munificent donations were received in consequence of the appeal. The printed books now number nearly 40,000, chiefly on Indian and Oriental subjects, with about 10,000 Sanskrit, Arabic, Persian, Farsi, and other Oriental manuscripts. Loth's excellent catalogue of the Arabic codices was published in 1877, and other catalogues are now ready for the press. At the Colonial Office there is a collection of about 12,000 works relating to colonial history and administration, and the Home Office possesses about 5000 volumes of parliamentary, historical, and legal works. The Admiralty library extends to about 25,000 volumes, chiefly voyages and travels; a printed catalogue was issued in 1875. At the War Office there are also 25,000 volumes, mainly topographical and military. The MS. records are estimated to extend to 100,000 volumes, but only those of the last twenty years are kept in Pall Mall, the remainder being at the Record Office. These records extend from the time of Queen Elizabeth, and there are some of earlier date. The older volumes belonged to the late Board of Ordnance,

and the series also includes the despatches from generals commanding armies on foreign service. All these libraries are for official use only, but at the India Office strangers are admitted upon proper introduction.

Many of the principal clubs possess libraries; that of the Athenæum is by far the most important. It now numbers about 48,000 volumes of books in all departments of literature, and is especially rich in well-bound and fine copies of works on the fine arts, archaeology, topography, and history. The pamphlets, of which there is a complete printed catalogue, as well as of the books, form a remarkable series, including those collected by Gibbon and Mackintosh. Next comes the Reform Club, with about 30,000 volumes, chiefly in belles-lettres, with a fair proportion of parliamentary and historical works. The Oxford and Cambridge Club has 20,000 volumes in general and classical literature. At the Garrick there is a small dramatic collection, and the United Service Club, besides a number of books on professional subjects, possesses the fine library which formerly belonged to Dugald Stewart.

A few libraries which could not be brought into any of the foregoing classes may now be spoken of. First comes the library of the Royal Geographical Society (1832), a valuable collection of 20,000 volumes of voyages and travels, and works on the sciences connected with geography, with many costly Government publications and geographical serials. The catalogue has been printed with supplements down to 1880. The maps and charts number 35,000, with 500 atlases and 240 large diagrams. Since 1864, in consideration of an annual grant of £500 from the treasury, the map room has been open for public reference. At the Royal United Service Institution there are also about 20,000 volumes, chiefly naval and military, with a printed catalogue, 1865. Besides the members, officers of both services are admitted. The Royal Asiatic Society has a library of nearly 8000 printed books, with 750 MSS. in Sanskrit, Persian, Turkish, &c, 5000 Chinese books, and 220 Japanese. Besides the art and educational libraries at South Kensington, there are also deposited at the museum, and open under the same regulations, the library of the Rev. Alexander Dyce, bequeathed in 1869, and the books of John Forster, left in 1876. The Dyce collection (15,000 volumes) is strong in the English drama and poetry, Italian literature, and classical authors. The Forster library (19,000 volumes) abounds in history, biography, travels, plays, and fiction, tracts, Americana, proclamations, ballads, &c; the manuscript includes three note-books of Leonardo da Vinci, and the Garrick correspondence in 39 volumes.

Notices of a considerable number of other metropolitan libraries, not mentioned in the preceding pages, may be found in the tables at the end of this article.

With one or two exceptions, libraries are attached to the cathedrals of England and Wales. Though they are of course intended for the use of the cathedral or diocesan clergy, they are in most cases open to any respectable person who may be properly introduced. They seldom contain very much modern literature, chiefly consisting of older theology, with more or less addition of classical and historical literature. They vary in extent from a few volumes, as at Llandaff or St David's, to 15,000 volumes, as at Durham. Together they possess nearly 150,000 printed and manuscript volumes. As a rule, very little is spent upon them, and they are very little used.

The library of Christ Church, Oxford, belongs alike to the college and the cathedral, but will be more properly described as a college library. The cathedral library of Durham dates from monastic times, and possesses many of the books which belonged to the monastery. These were added to by Dean Saurby, the second founder of the library, and Bishop Coeln. The collection has been considerably increased in more modern times, and now contains

15,000 volumes. It is especially rich in MSS., some of which are of great beauty and value; a catalogue of them was printed in 1825. The library has good topographical and entomological collections. The chapter spent £370 per annum in salaries and in books. The library at York numbers about 11,000 volumes, and has been very liberally thrown open to the public. It is kept in the former chapel of the archbishop's palace, and has many valuable MSS. and early printed books. The foundation of the library at Canterbury dates probably from the Roman mission to England, 598 A.D., although the library does not retain any of the books then brought over, or even of the books said to have been sent by Pope Gregory to the first archbishop in 601. It is recorded that among Leofric's buildings was a new library, and Becket is said to have collected books abroad to present to the library. The collection now numbers about 9000 printed books, with about 110 MS. volumes, and between 5000 and 7000 documents. A catalogue was printed in 1802. The present building was erected in 1367 on part of the site of the monastic dormitory. The library at Lincoln contains 7400 volumes, of which a catalogue was printed in 1859. It possesses a fine collection of political tracts of the age of Elizabeth, James, and Charles I. The present collection at Winchester dates from the Restoration only, that at Ely is rich in books and tracts relating to the non-union. The library at Exeter possesses many Saxon MSS. of extreme interest, one of them being the gift of Leofric, the first bishop. The treasure of Lichfield was destroyed by the Puritans during the civil war, and the existing library is of later formation. Frances, duchess of Somerset, bequeathed to it nearly 1000 volumes, including the famous *Evangelium* of St. Chad. The collection at Norwich is chiefly modern, and was presented by Dr. Sneyter. The earlier library at Peterborough having almost wholly perished in the civil war, Bishop White Kennett became the virtual founder of the present collection. Salisbury is rich in manuscripts, and a catalogue has recently been printed. Winchester Cathedral Library is mainly the bequest of Bishop Merley in the 17th century. The library at Bristol, then numbering 6000 or 7000 volumes, was burnt and pillaged by the mob in the riots of 1831. Only about 1000 volumes were saved, many of which were recovered, but few additions have been made to them. At Chester in 1691 Dean Aidenne bequeathed his books and part of his estate "as the beginning of a public library for the clergy and city." The library of Hereford is a good specimen of an old monastic library, the books are placed in the Lady Chapel, and about 230 choice MSS. are chained to oaken desks. The books are ranged with the edges outward upon open shelves to which they are attached by chains and bars. The four Welsh cathedrals were supplied with libraries by a deed of settlement in 1706. The largest of them, that of St. Asaph, has about 1750 volumes.

Oxford. The Bodleian Library, though it had been preceded by various efforts towards a university library, owed its origin to Sir Thomas Bodley. After a long and honourable career as a diplomatist he determined, as he says, to take his farewell of state employments, and concluded to set up his staff as the library door in Oxon. Contributing largely himself, and procuring contributions from others, he opened the library with upwards of 2000 volumes in 1602. In 1610 he obtained a grant from the Stationers' Company of a copy of every work printed in the country. The additions made to the library soon surpassed the capacity of the room, and the founder proceeded to enlarge it. By his will he left considerable property to the university for the maintenance and increase of the library. The example set by Bodley found many noble imitators. Amongst the chief benefactors have been Sir Henry Savile, Archbishop Laud, John Selden, Sir Kenelm Digby, Lord Fairfax, Richard Gough, Francis Douce, Richard Rawlinson, Rev. Robert Mason, and F. W. Hope. The library now contains almost 400,000 printed volumes, and about 30,000 manuscripts. The number of separate works exceeds a million. But the number of volumes conveys a very inadequate idea of the valuable character of the collection. In the department of Oriental manuscripts it is perhaps superior to any other European library; and it is exceedingly rich in other manuscript treasures. It possesses a splendid series of Greek and Latin *editiones principes*, and of the earliest productions of English presses. Its historical manuscripts contain most valuable materials for the general and literary history of the country.

The last general catalogue of the printed books was printed in 4 vols. folio, 1848-51. In 1859 it was decided to prepare a new

manuscript catalogue on the plan of the great catalogue at the British Museum, and this has recently been completed in duplicate. It extends to over 700 folio volumes, in which the books are entered on manifold slips. It is an alphabetical author-catalogue; and the Bodleian, like the British Museum, has no accessible subject index. A catalogue on subjects is now, however, in course of preparation. There are also printed catalogues of the books belonging to several of the separate collections. The MSS. are in general catalogued according to the collections to which they belong, and they are all indexed, although they are not all catalogued as yet. Five volumes have been published under the late Mr. Cooke's editorship of the "Catalogue Colmanianus. Bibliothecæ Bodleianæ," 1853-68, in quarto, and there is a folio catalogue of Oriental MSS.

In 1860 the beautiful building known as the "Radcliffe Library," now called the "Camera Bodleiana," was offered to the curators of the Bodleian by the Radcliffe trustees. It is used as a storeroom for the more modern books, including the new periodicals, which lie upon its tables, and it also serves as a reading-room. It is the only room open after the hour when the older building is closed owing to the rule as to the exclusion of artificial light. The separation of the books is a source of some inconvenience in practice, and it has been proposed of late years to remove the entire collections to a new building which should be erected for the purpose of accommodating them.

The library is open by right to all graduate members of the university, and to others (over eighteen years of age) upon producing a satisfactory recommendation. No books are allowed to be sent out of the library except by special leave of the curators, in which respect there is a marked contrast with the practice at the University Library at Cambridge, and still more so with the conspicuous liberality in this respect of the university libraries of Germany. The hours are from 9 to 4 and 9 to 10, according to the time of year, the Camera being open from 10 to 10 all the year round. The library is only closed altogether some twenty-two working days in the year. The general control of the library is committed to a board of thirteen curators. The permanent endowment is comparatively small, the ordinary expenditure, chiefly defrayed from the university chest, is about £4500.

The other important collections not connected with particular colleges are the Radcliffe Library and the library of the Taylor Institution. The former was founded by the famous physician Dr. John Radcliffe, who died in 1714, and bequeathed, besides a permanent endowment of £2850 a year, the sum of £40,000 for a building. The library was opened in 1715, and was at first intended to confine their purchases of books to works on medicine and natural science. When the university museums and laboratories were built in 1850, the trustees allowed the books to be transferred to the museum. The completeness and convenience of the arrangements make the Radcliffe works the most convenient of the university libraries. The Taylor Institution is due to the benefaction of Sir Robert Taylor, an architect, who died in 1788, leaving his property to found an establishment for the teaching of modern languages. The library was established in 1848, and is devoted to the literature of the modern European languages. It contains a fair collection of works on European philology, with a special Dante collection, about 1000 Masarnades and 400 Luther pamphlets. It contains altogether 80,000 volumes, with a few MSS. The French collection, left to the university in 1830, is also lent with the Taylor Library. Books are lent out to members of the university and to others on proper introduction. The endowment affords an income of £6000 to £1000 for library purposes, and about 2000 volumes are added yearly.

The libraries of the several colleges vary considerably in extent and character. That of All Souls was established in 1449 by Archbishop Chichele, and enlarged in 1710 by the munificent bequest of Christopher Codrington. It devotes special attention to jurisprudence, of which it has a large collection. It possesses 40,000 printed volumes and 300 MSS., and fills a splendid hall 200 feet long. The library of Brasenose College has a special endowment fund, so that it has, for a college library, the unusually large income of £2000. The library of Christ Church is rich in diversity and topography. It embraces the valuable library bequeathed by Charles Boyle, third earl of Orrery, amounting to 15,000 volumes, the books and MSS. of Archbishop Wake, and the Morris collection of Oriental books. The building was finished in 1791, and closely resembles the building of Antonine at Rome. The new Doge's Library possesses a fine collection of Aldine, many of them presented by its founder Bishop Fox, and a collection of 17th century tracts catalogued by Mr. Edwards, with about 400 MSS. Exeter College Library has 55,000 volumes, with special collections of classical dissertations and English theological and political tracts. The library of Jesus College has few books of later date than the early part of the last century. Many of them are from the bequest of Sir Leoline Jenkins, who built the existing library. There are also some valuable Welsh MSS. The library of Keble College consists largely of theology, including the MSS. of many of Keble's works. The library of Magdalen College has about 25,000 volumes (including

many volumes of pamphlets) and 250 MSS. It has scientific and topographical collections. The library of Merton College has of late devoted itself to foreign modern history. New College Library has about 17,000 printed volumes and about 350 MSS., several of which were presented by its founder, William of Wykeham. Oriel College Library, besides its other possessions, has a special collection of books on comparative philology and mythology, with a printed catalogue. The fine library of Queen's College is strong in theology, in English and modern European history, and in English county histories. St John's College Library is largely composed of the literature of theology and jurisprudence before 1760, and possesses a collection of medical books of the 16th and 17th centuries. The newer half of the library building was erected by Inigo Jones at the expense of Laud, who also gave many printed and manuscript books. The room used as a library of Trinity College formed part of Durham College, the library of which was established by Richard of Bury. Wadham College Library includes a collection of botanical books bequeathed by Richard Warner in 1776 and a collection of books, relating chiefly to the Spanish Reformers, presented by the executors of Benjamin Wiffen. Worcester College Library line of late specially devoted itself to classical archaeology. It is also rich in old plays.

It must be admitted that the college libraries as a rule have not been used to any great extent. Of late, however, there have been signs of awakening interest. About 1871 there was a meeting of college librarians, and it was agreed that the colleges, instead of making merely sporadic purchases from the whole field of literature, should rather husband their limited resources and restrict themselves each to some special department. But the idea has not been carried out very thoroughly, and a good deal must be done before the college libraries can be said to be as useful and efficient as they might be.

The history of the University Library at Cambridge dates from the earlier part of the 15th century. Two early lists of its contents are preserved, the first embracing 53 volumes dating from about 1423, the second a shelf-list, apparently of 330 volumes, drawn up by the outgoing proctors in 1473. Its first great benefactor was Thomas Scott of Rotherham, archbishop of York, who erected in 1475 the building in which the library continued until 1759. He also gave more than 200 books and manuscripts to the library, some of which still remain. The library received other benefactions, but nevertheless appeared "but mean" to John Evelyn when he visited Cambridge in 1654. In 1686 Tobias Rustat presented a sum of money to be invested by the college and made useful books. In 1715 George I. presented the library of Bishop Moore, which was very rich in early English printed books, forming over 30,000 volumes of printed books and manuscripts. The funds bequeathed by William Wote and John Manstre, together with that of Rustat, produce at present about £1000 a year. The share of university dues appropriated to library purposes amounts to £3000 a year. In addition the library is entitled to new books under the Copyright Acts. The number of printed volumes in the library cannot be exactly stated, as no recent calculation on the subject exists. It has been variously estimated at a quarter or half a million. The calendar states it as 200,000. It includes a fine series of *éditions principes* of the classics and of the early productions of the English press. The MSS. number 5723, in which are included a considerable number of adversaria or printed books with MS. notes, which form a leading feature in the collection. The most famous of the MSS. is the celebrated copy of the four gospels and the Acts of the Apostles, which is known as *Codex Beza*, and which was presented to the university by that Reformer. A catalogue of the MSS. has been published in 4 vols., 1856-61. There is no printed catalogue of the books, although the catalogue is in print, the accessions being printed and cut up and arranged in volumes. The regulations of the library with regard to the lending of books are very liberal, as many as ten volumes being allowed out to one borrower at the same time.

There is a library attached to the Fitzwilliam Museum bequeathed to the university in 1816. It consists of the entire library of Lord Fitzwilliam, with the addition of an archaeological library bought

from the executors of Colonel Leake, and a small number of works, chiefly on the history of art, since added by purchase or bequest. It contains a collection of engravings of old masters, a collection of music, printed and MS., and a collection of illuminated MSS., chiefly French and Flemish, of the 14th to 16th centuries. The books are not allowed to be taken out.

The Library of Trinity College, which is contained in a magnificent hall built by Sir Christopher Wren, has about 90,000 printed and 1918 MS. volumes, and is especially strong in theology, classics, and bibliography. It owes to numerous gifts and bequests the possession of a great number of rare books and manuscripts. Amongst these special collections are the Orelli collection of early dramatic and especially Shakespearean literature, the collection of German theology and philosophy bequeathed by Archdeacon Hare, and the Grylls bequest in 1843 of 9600 volumes, including many early printed books. There are printed catalogues of the Sunken and other Oriental MSS. by Dr. Aufrecht and Professor Palmer, and of the manuscripts by the present librarian, Mr. Sinker. The library is open to all members of the college, and the privilege of using it is liberally extended to properly accredited students.

None of the other college libraries rivals Trinity in the number of books. The library of Christ's College received its first books from the founders. Clare College Library includes a number of Italian and Spanish plays of the end of the 16th century left by Giorgio Ruggia. The library of Corpus Christi College first became notable through the bequest of books and MSS. made by Archbishop Parker in 1575. The printed books are less than 5000 in number, and the additions now made are chiefly in such branches as throw light on the extremely valuable collection of ancient MSS. which attracts scholars from all parts of Europe. There is a printed catalogue of these MSS. Gonville and Caius College Library is of early foundation. A catalogue of the MSS. was printed in 1849, with pictorial illustrations, and a list of the manuscripts in 1860. The printed books of King's College includes the fine collection bequeathed by Jacob Bryant in 1804. The MSS. are almost wholly Oriental, chiefly Persian and Arabic, and a catalogue of them has been printed. Magdalene College possesses the curious library formed by Pepys and bequeathed by him to the college, together with his collections of prints and drawings and of rare British portraits. It is remarkable for its treasures of popular literature and English ballads, as well as for the Scottish manuscript poetry collected by Sir Richard Martin. The books are kept in the library's own cases, and remain just as he arranged them himself. The library of Peterhouse is the oldest library in Cambridge, and possesses a catalogue of some 600 or 700 books dating from 1418, in which year it was completed. It is chiefly theological, though it possesses a valuable collection of college records on genealogy and natural science, and a unique collection of MSS. on the history of the college. The library of St John's College is rich in early printed books, and possesses a large collection of English historical tracts. Of the MSS. and rare books there is a printed catalogue. For the other college libraries see the tables.

Free Public Libraries.—In the year 1850 Mr. Ewart Free introduced the first Public Libraries Act into the House of Commons, and it has since been supplemented and amended by the Acts of 1856, 1866, 1871, and 1877. Mr. Ewart had previously carried through parliament the Museums Act of 1845, and small libraries had been established in connexion with museums under that Act at Salford and Warrington. The number of towns which have established rate-supported libraries, or in which the Acts have been adopted, now amounts to at least ninety-six, ten of these towns being in Scotland, and one only in Ireland. It is noticeable that the Acts have not been adopted in any of the great capital towns of the three kingdoms, except in one single parish of Westminster. Many of our largest towns are also in default. Glasgow may be considered to be sufficiently provided for by the magnificent Mitchell bequest. Of the libraries which have actually been opened sixteen are in places of over 100,000 inhabitants, twenty in towns of between 50,000 and 100,000 inhabitants, sixteen in towns of between 30,000 and 50,000, eleven in towns of between 20,000 and 30,000 inhabitants, seventeen in towns of between 10,000 and 20,000 inhabitants, and finally six in towns of less than 10,000 inhabitants.

Taking the latest returns we have been able to obtain,

which are with a few exceptions those of the year 1880-81, the number of volumes in stock and of the total issues is as follows. In eighty-one libraries returning their number of volumes, there is a total of 1,448,182 volumes in stock, while the total issues for the year in seventy-six libraries amounted to the enormous number of 9,033,742 volumes. Even these figures afford a very inadequate idea of the service rendered by these institutions in supplying popular reading. They take no account of the visits made to the newsrooms which are almost invariably connected with the libraries, or of the use made of the magazines and periodicals which lie upon the tables. The free public libraries generally consist of a lending department, with a reference library wherever the institution can provide one. A very large proportion of the issues from the lending departments consists of fiction, the percentage varying in different libraries from about 50 to as much as 75 per cent. of the whole. It is only in the case of the wealthier institutions, such as those in the great towns of Liverpool, Manchester, and Birmingham, that the reference departments are so important as to claim consideration here in respect of the intrinsic character of their collections. Even some of the smaller libraries, however, present features of interest in their collections of local books, or of books illustrating the trade or industry of the district, or the life and writings of some great man connected with or born in the locality.

The Salford Free Public Library was one of the libraries which were established under the Museums Act of 1845, and was opened in 1850 in connexion with the museum and picture gallery at Peel Park. The buildings are pleasantly situated in grounds of 46 acres in extent. The reference library now contains 85,600 volumes, and besides the central lending departments there are three branches in different parts of the borough. The income from the penny rate is about £2800, but this is found to be inadequate.

The Manchester Free Library was the first to be established under the Acts of 1850. A public subscription of nearly £13,000 was raised to defray the expenses of its establishment, and the library was opened in September 1852. The working of the library was a success from the first. The issue in the first year was 100,000 in the reference departments 61,080 volumes, and in the lending departments 77,232. The progress made since then may be measured by the number of volumes issued last year (1881), which amounted to 966,468, and by the fact that six branch libraries have been established. The rate produces an income of £21,000. The reference library now possesses a valuable collection of 65,000 volumes, chiefly of standard works. It contains several special collections, chiefly connected with the industries and history of the district. The library of the English Dialect Society, of which a catalogue has been printed, is deposited here. In addition, the library possesses a very extensive series of periodicals, and a larger collection of political and commercial tracts than can be found anywhere in the country except at the British Museum. A good catalogue was printed in 1864, and a new and extensive index has just appeared.

The library at Liverpool, which was established under a special Act passed in 1852, is the most successful of all the free public libraries, and is connected with a splendid museum and art gallery, the former formed around the nucleus of the ornithological specimens bequeathed to the town by the thirteenth earl of Derby. The rapid extension of museum and library soon rendered larger premises a necessity. The late Sir William Brown took upon himself the entire cost of the present extensive buildings, which were opened in 1860. In 1880 was opened the Pictorial Reading-Room. It is a circular room 100 feet in diameter, surmounted by a dome, the entire height being 55 feet. It contains 50,000 volumes, and will accommodate over 300 readers. Since April 1881 the electric light has been employed. Under the reading-room is a large circular lecture-room accommodating 1600 persons, in which lectures are regularly delivered. There is a numerous collection of local books and pamphlets. The library collection, consisting of maps, plans, drawings, portraits, &c., all having reference to the county of Lancashire, is very interesting and valuable. The issues from the reference library in 1880 were 876,716, and with the issues from the two lending departments make the enormous aggregate of 1,307,131. The rate produces an income of £18,000 per annum, of which more than £2000 is expended upon the libraries. An elaborate catalogue of the reference library was published in 1872, and a supplement is now being printed. In 1858 Bolton established a library which now has a circulation

of over 240,000 volumes. In 1855 libraries were established at Birkenhead and Sheffield. At Birkenhead the rate produces £1500, and 130,000 volumes were lent out last year. At Sheffield, where the rate produces £4750, there are three branches, and the total issues last year were 884,996. The reference library has only 6000 volumes.

The Acts, after having been rejected at Birmingham in 1852, were adopted in 1860. By 1868 four branches had been opened in addition to the central reference and lending libraries. The issues from the lending departments last year were 400,000 volumes. The reference library consisted of over 50,000 volumes. The Shakespeare Memorial Library consisted of about 7000 volumes. There were also the Staunton Walsley collection of books and MSS and the Cervantes books. All these collections were unfortunately destroyed by a fire on January 11, 1879. The inhabitants of Birmingham have shown much public spirit in repairing the losses then sustained, so far as is possible, and the new central reference and lending libraries are expected to be open early in 1882, when it is anticipated that there will be as many volumes ready to be placed in the reference library as there were when the former library was destroyed. No town in England is so surrounded with free libraries as Birmingham. The rate at Birmingham produces over £2600.

The free library at Nottingham (1867) has recently had new quarters found for it in the new university buildings. It has two branches, and its issue are about 160,000. The rate produces £2200. The local collections include a Byron library. The library at Leeds (1868) has no less than twenty-one branches, and together they count over 100,000 volumes. The issues last year, in addition to the use made of the central reference library, were 630,618. The rate produces nearly £5000. At Leicester there is only a halfpenny rate, which produces about £300. The issues last year were 192,317. At Bradford (Acts adopted 1871) the rate produces £2800, and there are five branches with a circulation of 291,276 volumes, besides the use made of the reference library. At Plymouth (Acts adopted 1871, library opened 1876) the circulation was 171,851 last year, at Boscaldale (Acts adopted 1872) 168,614. At each place there is a collection of local literature, and at Boscaldale a collection of works on the woollen manufacture. The library at Newcastle, opened in 1880, has issued from its lending departments, in its first year, no less than 801,925 volumes to about 14,000 readers. A splendid building in course of erection will accommodate the reference library. This department is intended to contain a complete collection of all standard works, and also a collection of books and manuscripts relating to Newcastle and the northern counties generally. The rate produces £2800. At Bristol a town library had been established in 1814 by Robert Redwood and his family. The library in this has formed the nucleus of the collections formed under the Acts when they were adopted in 1875. The total number of volumes is about 46,000. The issues were 422,646 at the central library and its three branches. At Southampton (1875) Mr Atkinson gave the building called after him for a library and art gallery. The issues last year were 110,778. The rate produced £775, and an additional voluntary rate produced a little over £100 besides.

It will be seen from this summary statement that the libraries established under the Acts have in the cases mentioned been abundantly used. The merit of these results is very largely due to the enlightened energy of those who are entrusted with their administration.

Amongst the English libraries that have not yet been described there are a few that call for special mention. Some of these have been founded by individuals, and still bear their names. The first notable of these is the fine old library established by Humphrey Chetham at Manchester in 1565, which is still housed in the old collegiate buildings where Raleigh was once entertained by Dr Don. The collection consists largely of older literature, and numbers 6000 volumes, with 300 MSS. It is freely open to the public, and may be said to have been the first free library in England. Dr Shepherd's library at Preston was bequeathed by the founder, a physician of the town, to the corporation of Preston in trust for the inhabitants in the year 1759. It is a library of reference, accessible on recommendation from an alderman. The William Salt Library, a special Staffordshire library with numerous MSS, and other collections, formed to bring together materials for a history of Staffordshire, was opened to the public in 1874.

Some mention should be made also of the more important subscription or proprietary libraries, which were formed for the most part in the latter half of the 18th century. It is difficult for us to realise how few collections of books were accessible to the public of the last century even in London. The earliest circulating library in the metropolis was established about the middle of the century. The first in Birmingham was opened by Hutton in 1767. The idea of a proprietary library appears to have been first carried out at Liverpool in 1768. The library then formed still flourishes at the Lyceum, and possesses a collection of 72,000 volumes and an income of £1200 a year. In 1760 a library was founded at Warrington which has been merged

in the Warrington Museum. The Leeds library was established in 1788, and now has 88,000 volumes, and an income of £1430. In 1775 the Bristol museum and library was formed, and numbered Coleridge, Southey, and Lander among its earlier members. It now reckons 50,000 volumes, and an income of £1400 a year. The Birmingham (old) library was formed in 1778, and its rules were drawn up by Dr Priestley, who had already taken an active share in the management of the libraries at Warrington and Leeds. The library has now 40,000 to 50,000 volumes, and an income of £1800. Many similar institutions are noted in the tables, while others have given place to the trade circulating libraries and to the libraries established under the Free Libraries Acts.

A few modern collegiate libraries, finally, claim a summary notice. The library of the university of Durham dates only from 1833, and was begun by a gift of books from Bishop Van Mildert, to which many other donations have since succeeded. The fourth collection includes a large collection of early tracts. The Winton collection is chiefly classical, and the Malby collection classical and theological. The library of the Owens College, Manchester, was formed on the establishment of the college in 1851 by a gift of books from Mr James Heywood, F.R.S. It has since been largely increased by donations and purchases, including the libraries of Bishop Lee, Mr Croxall, and others. It has an endowment fund of £2500. The library at Stonyhurst College has gradually grown since the establishment of the college in 1794. There is a printed catalogue of books printed before 1661. The Welshman Library at St Mary's College, Oscott, was established by Bishop Walsh in 1839, having been purchased by him from the Marchese Marni. It has 70 MSS., and many early printed books.

Scotland. The principal library in Scotland is that of the Faculty of Advocates, who in 1680 appointed a committee of their number, which reported that "it was fit that, seeing if the recusants could be made pay their entire money, there would be betwixt three thousand and four thousand pounds in cash; that the same be employed on the best and fittest lawyers and other law books, conforme to a catalogue to be consigned upon by the Facultie, that the samen may be a fonde for aene Bibliothecque whereto many lawyers and others may leave their books." In 1682 the active carrying out of the scheme was committed to the Dean of Faculty, Sir George Mackenzie of Rosehaugh, who may be regarded as the founder of the library. In 1684 the first librarian was appointed, and the library appears to have made rapid progress, since it appears from the treasurer's accounts that in 1688 the books and furniture were valued at upwards of £11,000 Scots, exclusive of donations. In the year 1700, the rooms in the Exchange Stairs, Parliament Close, in which the library was kept, being nearly destroyed by fire, the collection was removed to the ground floor of the Parliament House, where it has ever since remained. The library retains the copyright privilege conferred upon it in 1709. The number of volumes in the library is computed to amount to 265,000; of the special collections the most important are the Astorga collection of old Spanish books, purchased by the faculty in 1824 for £4000; the Thorckellin collection, consisting of about 1200 volumes relating chiefly to the history and antiquities of the northern nations, and including some rare books on old Scottish poetry; the Dietrich collection of over 100,000 German pamphlets and dissertations, including many of the writings of Luther and Melancthon, purchased for the small sum of £80; and the Combe collection.

The faculty appear early to have turned their attention to the collection of MSS., and this department of the library now numbers about 3000 volumes. Many of them are of great interest and value, especially for the civil and ecclesiastical history of Scotland before and after the Reformation. There are thirteen monastic chartularies which escaped the destruction of the religious houses to which they belonged. The MSS. relating to Scottish church history include the collections of Spottiswoode, Woodrow, and Calderwood. The Woodrow collection consists of 154 volumes, and includes his correspondence, extending from

1694 to 1726. Sir James Balfour's collection and the Bellocars papers consist largely of original state papers, and include many interesting royal letters of the times of James V., Queen Mary, and James VI. The Sibbald papers, numbering over 30 volumes, are largely topographical. The Biddel notebooks, numbering 166 volumes, contain collections to illustrate the genealogy of Scottish families. There are about one hundred volumes of Icelandic MSS., purchased in 1825 from Professor Finn Magnusson, and some Persian and Sanskrit, with a few classical manuscripts. The department has some interesting treasures of old poetry, extending to 73 volumes. The most important are the Bannatyne MSS., in 2 vols. folio, written by George Bannatyne in 1568, and the Auchinleck MSS., a collection of ancient English poetry, named after Alexander Boswell of Auchinleck, who presented it in 1774.

The first catalogue of the printed books was compiled in 1692, and contains a preface by Sir George Mackenzie. Another was prepared under the care of Riddiman in 1742. In 1853 the late Mr Halkett commenced a catalogue, which has been printed in 6 vols. 4to, with a supplement, and includes all the printed books in the library at the end of 1871, containing about 260,000 entries. It is an illustration of the public spirit with which they conduct their library, that the whole cost of printing this extensive catalogue, over £5000, has been borne by the members of the faculty. The library, managed by a keeper and staff, under a board of six curators, is easily accessible to all persons engaged in literary work, and is for all practical purposes the public consulting library of Scotland.

The origin of the University Library of Edinburgh is to be found in a bequest of his books of theology and law made to the town in 1580 by Clement Little, advocate. This was two years before the foundation of the university, and in 1584 the town council caused the collection to be removed to the college, of which they were the patrons. As it was the only library in the town, it continued to grow and received many benefactions, so that in 1615 it became necessary to erect a library building. Stimulated perhaps by the example of Bodley at Oxford, Drummond of Hawthornden made a large donation of books, of which he printed a catalogue in 1637, and circulated an appeal for assistance from others. In 1673 the library received a bequest of 2000 volumes from the Rev. James Naime. In 1709 the library became entitled to the copy privilege, which has since been commuted for a payment of £275 per annum. In 1831 the books were removed to the present library buildings, for which a parliamentary grant had been obtained. The main library hall (190 feet in length) is one of the most splendid apartments in Scotland. One of the rooms is set apart as a memorial to General Reid, by whose benefaction the library has greatly benefited. Amongst the more recent accessions have been the Halliwell-Phillips Shakespeare collection, the Laing collection of Scottish MSS., the Baillie collection of Oriental MSS. (some of which are of great value), and the Hodgson collection of works on political economy. The library now consists of about 140,000 volumes of printed books with 2000 MSS.

The library of the Writers to Her Majesty's Signet was established by the society in 1755. At first it consisted of law books exclusively, but in 1788 they began to collect the best editions of works in other departments of literature. During the librarianship of Maevay Napier (1805-37) the number of volumes was more than sextupled, and in 1812 the library was removed to the new hall adjoining the Parliament House. In 1854 the upper hall was devoted to the collection. This is a magnificent apartment

142 feet long, with a beautiful cupola painted by Stothard. The library now contains nearly 70,000 volumes, exclusive of pamphlets, and includes some fine specimens of early printing, as well as many other rare and costly works. It is especially rich in county histories and British topography and antiquities. A catalogue of the law books was printed in 1856. The late David Laing, who became librarian in 1837, published the first volume of a new catalogue in 1871. The second volume is nearly completed. The books are lent out to the Writers and even to strangers recommended by them. This library, like that of the Advocates, is most liberally opened to literary inquirers, and has thus acquired a quasi-public or national character.

There are various other important libraries in Edinburgh, but no considerable lending library open freely to the poorest of the people, and two attempts which have been made to introduce the Librarians' Acts have been unsuccessful.

The first mention of a library at St Andrews is as early as 1469. The three colleges were provided with libraries of their own about the time of their foundation—St Salvator's 1465, St Leonard's 1512, St Mary's 1537. The University Library was established about 1619 by King James VI, and in the course of the 18th century the college libraries were merged in it. The copyright privilege was commuted in 1837. The collection numbers 90,000 volumes exclusive of pamphlets, with about 200 MSS, chiefly of local interest. About 1200 volumes are added yearly. A library is supposed to have existed at Aberdeen since the foundation of King's College by Bishop Elphinstone in 1494. The present collection combines the libraries of King's College and Mansel College, now incorporated in the university. The latter had its origin in a collection of books formed by the town authorities at the time of the Reformation, and for some time kept in one of the churches. The library was bequeathed by the Merchants, chiefly of classical books, and those of Henderson and Wilson, and contains some very valuable books. The general library is located in Old Aberdeen, while the medical and law books are in the New Town. The library has a grant, in lieu of the copy privilege, of £320. The library of the university of Glasgow dates from the 16th century, and among George Buchanan and many other distinguished men amongst its early benefactors. A classified subject-catalogue is in progress. The annual accessions are about 1500, and the commutation-grant £707. Connected with the university, which is trustee for the public, is the library of the Hunterian Museum, founded by the eminent anatomist Dr William Hunter. It is a collection of great bibliographical interest, as it is rich in MSS and in fine specimens of the early printing, especially in Greek and Latin classics. The printed books number about 18,000 volumes, and the MSS some 600 volumes. All the Scottish university libraries lend books to students, on deposit of £1, to graduates, for an annual subscription of half a guinea, and to persons engaged in literary research, by permission of the senatus.

The Mitchell Library at Glasgow bids fair to be the most important public library outside Edinburgh. It was founded by a bequest of £70,000 from the late Mr Stephen Mitchell. The library was opened in 1837, in temporary premises, and already contains over 80,000 volumes. It includes a special collection of Scottish poetry called "The Poets' Corner," and a collection of Glasgow literature, including early specimens of Glasgow printing. The library is open to all persons over fourteen years of age, and the number of readers during the first three years in which the library has been opened is believed to be without precedent. The number of volumes issued in 1880 was 890,782.

The English Libraries Act of 1850 was extended to Scotland in 1854, and the first town to put it into operation was Ayr, in 1856. The largest of the libraries which have been opened under the Act is at Dundee, which possesses 36,500 volumes with a circulation of 252,314. The rate produces £2390. Although the resources of the other towns in which the Acts have so far been adopted do not enable them to rival the larger English towns, the results are proportionately quite as satisfactory. The turnover of their stock of books is generally large, and the reading done appears to be more solid and serious than in England. The percentage of fiction issued is at least 10 or 15 per cent. below the average rate in the English free libraries.

Ireland. The establishment of the Library of Trinity College, Dublin, is contemporaneous with that of the Bodleian at Oxford, and it is an interesting circumstance that, when Challoner and Usher (afterwards the archbishop) were in London purchasing books to form the library, they met Bodley there, and entered into friendly intercourse and co-operation with him to procure the choicest and best

books. The commission was given to Usher and Challoner as trustees of the singular donation which laid the foundation of the library. In the year 1601 the English army determined to commemorate their victory over the Spanish troops at Kinsale by some permanent monument. Accordingly they subscribed the sum of £1800 to establish a library in the university of Dublin. For Usher's own collection, consisting of 10,000 volumes and many valuable MSS, the college was also indebted to military generosity. On his death in 1656 the officers and soldiers of the English army then in Ireland purchased the whole collection for £22,000 with the design of presenting it to the college. Cromwell, however, interfered, alleging that he proposed to found a new college, where the books might more conveniently be preserved. They were deposited therefore in Dublin Castle, and the college only obtained them after the Restoration. In 1674 Sir Jerome Alexander left his law books with some valuable MSS, to the college. In 1726 Dr Fallisier, archbishop of Cashel, bequeathed over 4000 volumes to the library, and ten years later Dr Gilbert gave the library nearly 13,000 volumes which he had himself collected and arranged. In 1741 the library received a valuable collection of MSS, as a bequest from Dr Stearne. In 1802 the collection formed by the pensionary Pagel, which had been removed to England on the French invasion of Holland, was acquired for £10,000. It consisted of over 20,000 volumes. In 1805 Mr Quin bequeathed a choice collection of classical and Italian books. There have been many other smaller donations, in addition to which the library is continually increased by the books received under the Copyright Act. The library now contains 192,000 volumes and 1880 MSS, and about 3000 volumes are added every year. There is no permanent endowment, and purchases are made by grants from the board. The whole collections are contained in one building, erected in 1739, consisting of eight rooms. The great library hall is a magnificent apartment over 200 feet long. A new reading-room was opened in 1848. A catalogue of the books acquired before 1873 is now in course of printing. There is no printed catalogue of the MSS. Graduates of Dublin, Oxford, and Cambridge are admitted to read permanently, and temporary admission is granted by the board to any fit person who makes application. Books and MSS are lent out only under special regulations. A lending library has been established to make provision for the needs of the students.

The public library, St Patrick's, Dublin, sometimes called Marsh's Library after its founder, was established about 1694 by Archbishop Marsh, was incorporated by Act of Parliament in 1707, and endowed by its founder at his death in 1718. The building was erected by the founder, and the original oak fittings still remain. There is no room for additions, and a large collection of modern books was added a few years ago on that account. The endowment is too small to allow of purchases from the funds of the library, so that it still retains the character of a 17th century library. The books are chiefly theological, and in the learned languages; they include the libraries of Bishop Stillingfleet and of Elias Brouncker, a French refugee, who was the first librarian.

The library of the Royal Dublin Society was commenced shortly after the formation of the society in 1781. With the exception of about 10,000 volumes of the publications of learned societies and scientific periodicals, with a few early editions, its books were transferred to the state, in 1877, to assist in forming the national library of Ireland. The manuscript collections of Walter Harris on Irish history were purchased and placed in the library for public use by the Irish parliament. The library of the Royal Irish Academy was established on the formation of the Academy in 1785, for the purpose of promoting the study of science, literature, and antiquities in Ireland. The library possesses about 40,000 printed volumes and about 1400 MSS. There is a large collection of MSS and books relating to the history, ancient language, and antiquities of Ireland. They include the Berham collection, acquired partly by public subscription in 1851. The library is partly supported by a Government grant of £200 per annum, and is freely open to a proper introduction. Under the direction of the present librarian

library, the publication of Irish MSS in the library was begun in 1870, and has since continued. The library of King's Inns was founded, pursuant to a bequest of books and legal MSS, under the will of Mr Justice Robinson in 1787, to form the nucleus of a library for law students. It is partly supported from the funds of the benchers, but partly also by a treasury grant of £438, 8s. 6d. in 1856 of the copy privilege. No books are lent out, and the use of the library is confined to students and barristers; so that the public has no advantage in return for the annual contribution of public money.

There is no library in Dublin corresponding in extent and public accessibility to the British Museum in London, or the Advocates' Library in Edinburgh. About 1860 it was proposed to supply the deficiency by combining the libraries of the Dublin Society and the Irish Academy, both of which had long received grants of public money, together with the collection of Archbishop Marsh. Accordingly in 1864 an Act of Parliament was passed "for the establishment of a national gallery and for the care of a public library in Dublin." The scheme thus authorized has never been carried out. In 1877, however, the National Library of Ireland was established in the apartments of Leinster House. The library is under the Science and Art Department of South Kensington, and is superintended by a body of twelve trustees in Dublin. For the last two years it has received an annual vote of £1000 from parliament for the purchase of books. As already mentioned, the books of the Royal Dublin Society have been transferred to it. It is freely open to the public on a respectable introduction, and is much used.

The public library of Armagh was founded by Lord Farnham in 1770, who gave a considerable number of books and an endowment. The books are freely available, either on the spot, or by loan on deposit of double the value of the work applied for. At Belfast the Queen's College Library has about 36,000 volumes, with a special collection of books on the languages and literature of the East. The library of the Queen's College, Cork, contains about 26,000 volumes, 1600 of the most valuable of which have been presented by Mr Crawford. The library is easily accessible to literary inquirers, and is much used by strangers. The library of Maynooth College is chiefly theological, and contains the collections bequeathed by the late Dr. Milnes and Messrs Russell. There are about 40,000 volumes and a few MSS.

Dundalk is at present the only town that has a library under the Public Libraries Act, which were adopted there in 1866. The rate produces only about £80.

France.

French libraries (other than those in private hands) belong either to the state, to the departments, to the communes, or to learned societies, educational establishments, and other public institutions; the libraries of judicial or administrative bodies are not considered to be owned by them, but to be state property. Besides the unrivalled library accommodation of the capital, France possesses a remarkable assemblage of provincial libraries. The communal and school libraries also form striking features of the French free library system.

Five and twenty years ago (see *Tableau statistique des bibliothèques publiques*, 1857) there were in the departments,—exclusive of those not literally free, and of all Parisian libraries,—340 public libraries containing 3,734,260 volumes and 44,436 MSS. In 1857 there were only 32 provincial libraries which owned more than 30,000 volumes each; there are now 64 which are of that extent and upwards.¹ In Paris there are now 16 containing over 30,000 volumes each.

Libraries of Paris.—The Bibliothèque Nationale (still the most extensive library in the world) has had an advantage over all others in the length of time during which its contents have been accumulating, and in the great zeal shown for it by several kings and other eminent men. Ecclesiastical writers find the original of this library in the MS. collections of Charlemagne and Charles the Bald, but these were dispersed in course of time, and the few precious relics of them which the national library now possesses have been acquired at a much later date. Of the library which St Louis formed in the 13th century

(in imitation of what he had seen in the East) nothing has fallen into the possession of the Bibliothèque Nationale, but much has remained of the royal collections made by kings of the later dynasties. The real foundation of the institution (formerly known as the Bibliothèque du Roi) may be said to date from the reign of King John, the Black Prince's captive, who had a considerable taste for books, and bequeathed his "royal library" of MSS. to his successor Charles V. Charles V. organized his library in a very effective manner, removing it from the Palais de la Cité to the Louvre, where it was arranged on desks in a large hall of three stories, and placed under the management of the first librarian and cataloguer, Claude Mallet, the king's valet-de-chambre. His catalogue was a mere shelf-list, entitled *Inventaire des Livres du Roy nostre Seigneur estans au chasteau du Louvre*; it is still extant, as well as the further inventories made by Jean Blanchet in 1580, and by Jean le Bègue in 1411 and 1424. Charles V. was very liberal in his patronage of literature, and many of the early monuments of the French language are due to his having employed Nicholas Oresme, Raoul de Presle, and other scholars to make translations from ancient texts. Charles VI. added some hundreds of MSS. to the royal library, which, however, was sold to the regent, duke of Bedford, after a valuation had been established by the inventory of 1434. The regent transferred it to England, and it was finally dispersed at his death in 1435. Charles VII. and Louis XI. did little to repair the loss of the precious Louvre library, but the news of the invention of printing served as a stimulus to the creation of another one, of which the first librarian was Laurent Paumier. The famous minister Jean Fouquet of Tours was named the king's *entremetteur*, and although Louis XI. neglected to avail himself of many precious opportunities that occurred in his reign, still the new library developed gradually with the help of confiscation. Charles VIII. enriched it with many fine MSS. executed by his order, and also with most of the books that had formed the library of the kings of Aragon, seized by him at Naples. Louis XII., on coming to the throne, incorporated the Bibliothèque du Roi with the fine Orleans library at Blois, which he had inherited. The Blois library, thus augmented, and further enriched by plunder from the palaces of Pavia, and by the purchase of the famous Gruthuyse collection, was described at the time as one of the four marvels of France. Francis I. removed it to Fontainebleau in 1534, enlarged by the addition of his private library. He was the first to set the fashion of fine artistic bindings, which was still more cultivated by Henry II., and which has never died out in France. During the librarianship of Amyot (the translator of Plutarch) the library was transferred from Fontainebleau to Paris, not without the loss of several books coveted by powerful thieves. Henry IV. removed it to the Collège de Clermont, but in 1604 another change was made, and in 1622 it was installed in the Rue de la Harpe. Under the librarianship of J. A. de Thou it acquired the library of Catherine de' Medici, and the glorious Bible of Charles the Bald. In 1617 a decree was passed that two copies of every new publication should be deposited in the library, but this was not rigidly enforced till Louis XIV.'s time. The first catalogue worthy of the name was finished in 1622, and contains a description of some 6000 volumes, chiefly MSS. Many additions were made during Louis XIII.'s reign, notably that of the Dupuy collection, but a new era dawned for the Bibliothèque du Roi under the patronage of Louis XIV. The enlightened activity of Colbert, one of the greatest of collectors, so enriched the library that it became necessary for want of space to make another removal. It was therefore in 1686 installed in the Rue Vivienne (now Vivienne) not far from its present habitat.

¹ In 1877 a questionnaire was issued in order to obtain materials for a more complete report, but the results have not yet been made public.

The departments of engravings and medals were now created, and before long rose to nearly equal importance with that of books. Marolle's prints, Fouquet's books, and many from the Mazarin library were added to the collection, and, in short, the Bibliothèque du Roi had its future pre-eminence undoubtedly secured. Nic. Clément made a catalogue in 1684 according to an arrangement which has been followed ever since (that is, in twenty-three classes, each one designated by a letter of the alphabet), with an alphabetical index to it. After Colbert's death Louvois emulated his predecessor's labours, and employed Mabillon, Thvenot, and others to procure fresh accessions from all parts of the world. A new catalogue was compiled in 1688 in eight volumes by several distinguished scholars. This Abbé Louvois, the minister's son, became head of the library in 1691, and opened it to all students—a privilege which although soon withdrawn was afterwards restored. Towards the end of Louis XIV.'s reign it contained over 70,000 volumes. Under the management of the Abbé Bignon numerous additions were made in all departments, and the library was removed to its present home in the Rue Richelieu. Among the more important acquisitions were 6000 MSS. from the private library of the Colbert family, Bishop Huet's forfeited collection, and a large number of Oriental books imported by missionaries from the further East, and by special agents from the Levant. Between 1739 and 1753 a catalogue in eleven volumes was printed, which enabled the administration to discover and to sell its duplicates. In Louis XVI.'s reign the sale of the La Vallière library furnished a valuable increase both in MSS. and printed books. A few years before the Revolution broke out the latter department contained over 300,000 volumes and opuscles. The Revolution was servicable to the library, now called the Bibliothèque Nationale, by increasing it with the forfeited collections of the *émigrés*, as well as of the suppressed religious communities. In the midst of the difficulties of placing and cataloguing these numerous acquisitions, the name of Van Praet appears as an administrator of the first order. Napoleon increased the amount of the Government grant; and by the strict enforcement of the law concerning new publications, as well as by the acquisition of several special collections, the Bibliothèque made considerable progress during his reign towards realizing his idea that it should be universal in character. At the beginning of this century the recorded numbers were 200,000 printed volumes, 83,000 MSS., and 1,600,000 engravings. After Napoleon's downfall the MSS. which he had transferred from Berlin, Hanover, Florence, Venice, Rome, the Hague, and other places had to be returned to their proper owners. The MacCarthy sale in 1817 brought a rich store of MSS. and incunabula. From that time onwards to the present, under the enlightened administration of MM. Taschereau and Delisle, the accessions have been very extensive.

The official estimate of the number of volumes in the *Département des Imprimés* now reaches the extraordinary total of about 3,200,000, but the contents have not been actually counted since 1791, and so the above enumerates pieces of which many are included in one volume, perhaps something like 1,837,000 is nearer the proper number. The annual additions are about 45,000. The *réserve* (consisting of articles of the highest importance) extends to more than 60,000 volumes. The collection of books on French history is in itself an enormous library, amounting to 440,000 volumes. The maps and charts, added to number 800,000, are included in this department. The *Département des MSS.* comprehended, in 1876, 91,700 volumes. The *Département des Médailles* possessed, in 1875, 144,000 coins, medals, engraved stones, &c., and since that date has acquired many important accessions. More than 2,300,000 engravings are in the *Département des Estampes*, where 200,000 pieces are annually received under the copyright law. The annual vote for purchases and binding is 200,000 francs.

Admittance to the *Salle de Travail* is obtained by a *bulletin*

personnel, which is procurable without difficulty. Thus, the reading-room for students, was built in 1838, and affords accommodation for 344 readers. There are but few books of reference, and readers are only allowed five books a day. The *Salle publique* contains 40,000 books, which are freely available to the public. Plans are now under consideration for an enlargement of the Bibliothèque, and a sum of 3,700,000 francs is to be devoted to that purpose.

The Bibliothèque Nationale does not possess a general catalogue at the disposal of readers, the MS. catalogues of the various classes of the printed books are for official use only. Besides the old catalogue of 1789-99, there is the very elaborate *Catalogue de l'Édition de France* (1865-73, 11 vols. 4to), with a *Supplément*, the indexes will appear shortly. The third volume of the *Catalogue des Sciences Médicales* is now in the press, and that devoted to English history is nearly finished in manuscript. The vellum books have been described by Van Praet (1822-26, 6 vols. 8vo, and supplement 1877). The MSS. are much better provided for. The printed catalogues of these commence with that of Annet Molot, 1750-44, 4 vols. folio, continued in a way by the *Notices et Extraits des MSS. du Bibl. du Roi*, 1737-1875. The work of M. Paulin Paris, *Les MSS. Français; leur histoire et celle des textes antérieurs, anglais, italiens, et espagnols* (1880-86, 7 vols. 8vo), is well known. Catalogue of the Italian, Spanish, Belgian, Sanskrit, Ethiopic, and Chinese MSS. have also appeared between 1807 and 1844. The first and second volumes in 4to of a new *Catalogue des MSS. Français* have been printed, and two volumes of the *Revue de M. Delisle*, besides five parts of his *Revue des MSS. Latins* (1868-71). The authorities have also brought out a *Catalogue des Manuscrits Hébreux et Samaritains* (1868, 4to), besides those of *MSS. Syriques et Sabéens* (1874, 4to), *MSS. Ethiopiques* (1877), and *MSS. Espagnols* (1879).

Paris is much better provided than London or any other city in the world with great public libraries. Besides the Bibliothèque Nationale there are four libraries, each over 120,000 volumes (with others less extensive), to which the public have free access, the Bibliothèque de l'Arsenal being the largest of them. The collection of the Marquis de Paulmy d'Argenson was the basis of this library, which also acquired a portion of the books of the Duc de la Vallière in 1781. It is peculiarly rich in romances, the drama, French poetry, and possesses 80,000 volumes on French history alone. It is freely open, but there are not many readers.—The Bibliothèque Mazarine was founded by the great cardinal, who in 1643 placed about 12,000 volumes at the disposal of the public. The books were chiefly brought together by him. It was opened to the public in 1790, and at the time of the Revolution there were 80,000 printed volumes and 2000 MSS.; there are now 150,000 volumes and 2892 MSS. The reading-room is open in the evening, and is much frequented, especially by students. The library contains a good collection of incunabula, many of which have been described by Dibdin, a number of rare Italian and Spanish chronicles, and a very complete series of periodicals from the 17th century to the empire.—The Bibliothèque de l'Université (or the Sorbonne) was formerly restricted to the use of the members of the five faculties of Paris, but the public has been freely admitted since the time of the Revolution, was destroyed in 1871. It has since been entirely re-established in the Hôtel Carnavalet, which contains the historical museum of the city, and comprehends 80,000 volumes of books and 40,000 engravings, entirely relating to the history and description of Paris. The other public libraries are under the authority of the minister of public instruction, but the Bibliothèque de la Ville is under the control of the prefect of the Seine. The municipal libraries in Paris are 30 in number, with 70,000 volumes; there are besides 440 school libraries, with 44,120 books.

Of other libraries in Paris, not included in our tables, we may name the Bibliothèque de la Préfecture de Police (10,000 volumes, with various MSS. relating to the Revolution), Bibliothèque de

Nationale de première instance (28,900 volumes). Bibliothèque de l'École Polytechnique (50,000 volumes). Bibliothèque de l'École Normale (24,000 volumes, which acquired the library of Georges Cuvier in 1838). Bibliothèque des Javalais (23,000 volumes, a good collection on history and military affairs). Bibliothèque de l'École Nationale des Beaux Arts (11,000 volumes, 13,000 drawings, 100,000 prints and photographs). Bibliothèque du Conservatoire de Musique (30,000 volumes, one of the finest collections of musical literature in the world). Bibliothèque des Archives Nationales (founded by Danon in 1808, containing 26,000 volumes on paleography, history, and jurisprudence,—as this is the record office of France, the archives are very extensive). Bibliothèque du Luxembourg (25,000 volumes). Bibliothèque du Lycée Louis le Grand (30,000 volumes). Bibliothèque du Ministère de l'Intérieur (17,000 volumes, including Parisian and provincial history and documents).

Pro-
vinces of
France.

Besides the various collections belonging to learned and scientific societies, educational institutions, and other bodies, outside Paris, over 215 French provincial towns possess public libraries, which range in number of volumes from 2000 or 3000 to 180,000, as at Bordeaux. Most of them were founded at the end of the last or the beginning of the present century, but some are earlier. The library at Lyons was established by Francis I. in 1530, that at Nantes dates from 1558, La Rochelle from 1604, Albi, Clermont, Besançon, and Troyes from the latter part of the same century, and Orléans from the beginning of the 17th century. The large majority were formed by confiscation at the time of the Revolution. In February 1790 the Assemblée Nationale abolished the different religious communities, and in September of the same year the provincial tribunals and parliaments met with the same fate. The books (said to number 10 or 12 millions) of these corporations were declared national property, a committee was appointed to consider what should be done with them, and a general catalogue of all the sequestered effects ordered to be drawn up. In consequence of the recommendations of the committee, the Convention Nationale (January 27, 1794) decreed the establishment and augmentation of public libraries. The orders of the Convention were not carefully executed, and pitiable stories are told of valuable works sold by the yard as they lay upon the ground, of precious manuscripts and printed rarities left to rot in the rain or burnt for fuel. As the government became more settled, the libraries (when not destroyed) of condemned persons were restored to their representatives. A very large number of books still remained, however, and it is to them that the town libraries of France chiefly owe their riches. Theology, law, history, and the sciences before the 17th and 18th centuries consequently predominate, although for many years more modern requirements have been mainly considered in the acquisition of books. Many collections of local and provincial literature have been formed, as at Angers, Angoulême, Chartres, Grenoble, La Rochelle, Lille, Marseilles, Orléans, Rouen, Toulon, Troyes, and Versailles. Some of the libraries are very extensive. Douai and Troyes have 100,000 volumes each; Lyons and Rouen over 120,000; Besançon, 130,000; Aix and Nantes, 150,000; Grenoble, 170,000; and Bordeaux, 190,000 volumes. All have catalogues, mostly alphabetical; a few of them are in print. The *Catalogue général des MSS. des bibliothèques publiques des départements* is a noble undertaking on the part of the French Government. The first volume came out in 1846, and the latest, the sixth, in 1879; the treasures of eighteen libraries have now been catalogued (about 9500 MSS.), and there remain over 46,000 MSS. to be described. Besides this, Angers, Angoulême, Angoulême, Caen, Clermont, Chartres, Orléans, and Troyes possess separate printed catalogues of their MSS. The chambers annually vote large sums for books, which are distributed to the town libraries by the minister of public instruction. The sums granted by the different municipalities for their libraries vary in amount; for instance, Grenoble 170,000 volumes and eight persons employed gives 25,314 francs, Bordeaux (190,000 volumes and eight persons) 21,350 francs, and Nantes (160,000 volumes and four persons) 18,400 francs.

Popular libraries of every description, including military and women's libraries, were made to the "Société Franklin pour la propagation des bibliothèques populaires," which, founded in 1849, has since been of immense service in organizing and helping those institutions. Between 1868 and 1878 the Société had spent 560,000 francs on these purposes. It issues a *Catalogue Populaire* of a good selection of recommended books, and publishes a journal of its proceedings.

School libraries had an organized existence in France as far back as 1851, and by 1848 the books which had been distributed by the state amounted in value to 2 millions of francs, two years later, however, no trace of books or libraries could be found. In 1860 a question was again taken up, and in 1869 the minister of public instruction ordered that in every primary school a library should be established under the care of the schoolmaster. For some years the Government annually granted 120,000 francs, a sum which was raised to 200,000 francs in 1878, for their share

of the expenses the departments contributed in 1875 as much as 170,000 francs. As an instance of the rapidity with which the school libraries have increased, it may be stated that Haute-Marne, which only possessed 44 of them in 1866, ten years later had 548, in 1877 there were about 17,764 *bibliothèques scolaires* in France. The libraries, which are intended not only for the use of school children but also for their parents and other adults, are regulated by a commission sitting at the ministry of public instruction.

Germany (with Austria and Switzerland).

Germany is emphatically the home of large libraries; Germany her want of political unity and consequent multiplicity of capitals have had the effect of giving her a considerable number of large state libraries, and the number of her universities has tended to multiply considerable collections.

Berlin is well supplied with libraries, seventy-two being Berlin, registered by Petzholdt in 1875, with about 1,393,030 printed volumes. The largest of them is the Royal Library, which was founded by the "Great Elector" Frederick William, and opened as a public library in a wing of the electoral palace in 1661. From 1699 the library became entitled to a copy of every book published within the royal territories, and it has received many valuable accessions by purchase and otherwise. It is now estimated to contain upwards of 700,000 printed volumes and over 15,000 MSS. The amount yearly expended upon binding and the acquisition of books, &c., is 24800. The catalogues are in manuscript, and include a general alphabetical author-catalogue, and a systematic subject-catalogue in a handy form. The building, erected about 1780 by Frederick the Great, has long been too small, and a new one is in contemplation. The conditions as to the use of the collections are, as in most German libraries, very liberal. Any adult person is allowed to have books in the reading-room. Books are lent out to all higher officials, including those holding educational offices in the university, &c., and by guarantee to almost any one recommended by persons of standing; admission to the journal-room is more strictly limited. By special leave of the librarian, books and MSS. may be sent to a scholar at a distance, or, if especially valuable, may be deposited in some public library where he can conveniently use them. There appears to be no limit to the number of books which may be borrowed, although it is prescribed that not more than "three works" must be asked for on one day. Professor Lepsius reports the issues for last year as 71,400 works, to above 5000 readers. The University Library (1831) numbers 200,000 volumes with 353 MSS. The number of volumes lent out in 1830 was 40,101. The library possesses the right to receive a copy of every work published in the province of Brandenburg. Some of the governmental libraries are important, especially those of the Military Academy and the General Staff, which was increased in 1873 by acquiring the library of the "École d'Application" at Metz. In 1850 some popular libraries were established by a society for giving scientific lectures. There are now thirteen such libraries with over 54,000 volumes, but the yearly number of readers is only about 12,000.

The libraries of Munich, though not so numerous as those of Berlin, include two of great importance. The Royal Library, the largest collection of books in Germany, was founded by Duke Albrecht V. of Bavaria (1550-79), who made numerous purchases from Italy, and incorporated the libraries of the Nuremberg physician and historian Schedel, of Wilmannsstadt, and of J. J. Fugger. The number of printed volumes is estimated at about one million, although it is long since any exact enumeration has been made. The library is especially rich in incunabula, many of them being derived from the libraries of the monasteries closed in 1803. The Oriental MSS. are

¹ See Du Wettstein, *Rapport sur les Bibliothèques scolaires*, 1879.

numerous and valuable, and include the library of Martin Haug. The amount annually spent upon the library is £4600, of which £2080 is expended upon books and binding. The catalogue of the printed books are in manuscript, and include (1) a general alphabetical catalogue, (2) an alphabetical repertorium of each of the 195 subdivisions of the library, (3) biographical and other subject catalogues. A printed catalogue of the MSS. in 8 volumes is nearly complete; the first was published in 1858. The library is open only twenty-nine hours during the week, while the Royal Library at Berlin is, except in the three winter months, open for thirty-nine. The library of the British Museum is now open for sixty-six hours per week, but it lends no books out. The regulations for the use of the library are very similar to those of the Royal Library at Berlin. The building erected for this collection under King Louis I. in 1832-43 is regarded as a model library structure. The archives are bestowed on the ground floor, and the two upper floors are devoted to the library, which occupies seventy-seven apartments.—The University Library was originally founded at Ingolstadt in 1472, and removed with the university to Munich in 1826. It participated in 1803 in the division of the literary treasures of the disestablished monasteries. At present the number of volumes in the general library amounts to 290,000, besides which several special collections are also deposited in the library to the number of 32,800 volumes. The MSS. number 1744. The various libraries of Munich have upwards of 1,400,000 volumes.

Dresden. Dr Petzholdt has registered no less than 49 libraries in Dresden, where indeed his inquiries were likely to be particularly exhaustive. The Royal Public Library in the Japanese Palace was founded in the 18th century. Among its numerous acquisitions have been the library of Count Bunsen in 1764, and the manuscripts of Albert. Special attention is devoted to history and literature. The library does not claim to possess more than 800,000 volumes, although Petzholdt in 1875 reckoned them as at least 800,000 printed books, as well as 400,000 dissertations. The MSS. number 8500 volumes. Admission to the reading-room is granted to any respectable adult on giving his name, and books are lent out to persons qualified by their position or by a suitable guarantee. Here, as at other large libraries in Germany, works of belle-lettres are only supplied for a literary purpose. The number of persons using the reading-room in a year is about 3500, and about 10,000 works (not volumes) are lent to about 500 readers.—The "Französische Secundär-Gesamte" Library, now in the possession of Prince George of Saxony, and of which Dr Petzholdt, the Director of bibliographers, is librarian, is a private library to which access is permitted.

Stuttgart. The Royal Public Library of Stuttgart, although only established in 1765, has grown so rapidly that it now possesses about 425,000 "numbers" of printed works and 8500 MSS. There is a famous collection of Bibles, containing 7200 volumes. The annual expenditure is about £2540, of which £1254 is devoted to books and binding. The library also enjoys the copy-privilege in Württemberg. "The borrowing of books for home use is open to all members of the German empire resident in Stuttgart, whose personal and economic circumstances offer the necessary guarantee for the safety of the national property. The library may, moreover, be used from any part of Württemberg on payment of the cost of carriage." The annual number of borrowers is over 1800, who use nearly 17,000 volumes. The number used in the reading-room is at least twice as great. The number of parcels despatched from Stuttgart is nearly 900.—Admission is also freely granted to the Royal Private Library, founded in 1810, which contains about 50,000 volumes and 900 MSS. The other libraries of Stuttgart, of which Petzholdt reckons 11, are not of importance.—The Grand-ducal Library of Darmstadt was established by the grand-duke Louis I. in 1817, on the basis of the still older library formed in the 17th century. The number of volumes used in the course of the year is about 30,000, of which 8000 are lent out to about 5000 readers.—The Ducal Library of Gotha was established by Duke Ernest the Pious in the 17th century, and contains many valuable books and MSS. from monastic collections. It numbers about 240,000 volumes, with upwards of 6000 MSS. The catalogue, now in course of publication, of the Oriental MSS. chiefly collected by Seetzen, and forming one-half of the collection, is one of the best in existence. Other great Ducal Libraries are noticed in the tables.

Literatures of medicine, art and invention are attached to all

the twenty-one universities of Germany, most of them being several Universities with the universities themselves. Thus the oldest library is that of Strasbourg, which in its earlier form dates from 1386. In 1608 it became so important that Joseph Scaliger wrote of it "Lectio-plectus est meliorum librorum quam Vaticanum." In 1628 the library was carried to Rome as a present to the pope, but some of the treasures were ultimately restored. The later collection was first formed in 1703. The collection of MSS. is extremely valuable.

—The library of Leipzig university dates from 1409, although it was not until the middle of the 16th century that it was properly organized.—The library of Göttingen owes much to the labours of the illustrious Heyne. It ranks as one of the most complete and best arranged of the German libraries. New buildings for its accommodation are in course of erection.—The library at Strasbourg, although founded only in 1871 to replace that which had been destroyed in the siege, already ranks amongst the largest libraries of the empire. Its books and MSS. together amount to 513,000. The remaining university libraries are noticed in the tables.

Some of the town libraries of Germany mentioned in the tables were amongst the earliest established after the revival of learning. The oldest of them is perhaps that of Ratibon, which was founded at least as early as 1480. Since Ratibon has ceased to be an imperial city it has had to part with many of its treasures to the library at Munich.

The whole number of libraries in the German empire, as accounted by Dr Petzholdt in 1847, distributed amongst 584 towns

A report issued in 1873-74 by the Austrian Statistical Commission, furnishes an account of the condition of the libraries in those portions of Austria which are represented in the Reichsrath, as they were at the end of the year 1870. The number of libraries registered was 577, of which 23, however, were private libraries. Of the rest 159 belonged to religious corporations and seminaries, 105 were military libraries, 66 belonged to literary and scientific societies, 189 were of an educational and scholastic, and the remaining 45 of a public character.

The largest library in Austria, and one of the most important collections in Europe, is the Imperial Public Library at Vienna, apparently founded by the emperor Frederick III. in 1440, although its illustrious librarian Lambecius, in the well-known inscription over the entrance to the library which summarizes its history, attributes this honour to Frederick's son Maximilian. However this may be, the munificence of succeeding emperors greatly added to the wealth of the collection, including a not inconsiderable portion of the dispersed library of Corvinus. Since 1808 the library has also been entitled to the copy-privilege in respect of all books published in the empire. The sum devoted to the purchase of books is 26,250 florins annually. The main library apartment is one of the most splendid halls in Europe. Admission to the reading-room is free to everybody, and books are also lent out under stricter limitations.—The University Library of Vienna was established by Maria Theresa. The reading-room is open to all comers, and the library is open much longer than is the rule with university libraries generally. In winter, for instance, it is open from 5 to 8 in the evening, and it is even open from 9 to 12 on Sundays. In 1879, 159,768 volumes were used in the library, 16,800 volumes lent out in Vienna, and 4418 volumes sent carriage free to borrowers outside Vienna. The total number of libraries in Vienna enumerated by Dr Petzholdt is 101, and many of them are of considerable extent.

The number of monastic libraries in Austria is very considerable. Monastic Particulars are furnished, in the report already quoted, of 107 of libraries then, varying from a few hundreds of volumes to as many as 80,000. Many other such libraries are known to exist in the 468 monasteries.—The oldest of them, and the oldest library in Austria, is that of the monastery of St Peter at Salzburg, which was established by St Rupert in the 6th century. It possesses 60,000 volumes, with nearly 30,000 manuscripts. The four next in point of antiquity are Kremsmünster (50,000), Lambach (25,000), Admont (20,000), and Melk (16,000), all of them dating from the 11th century. Of the 147 libraries enumerated in the report, 56 possessed 5000 volumes or upwards at the end of 1870. For further particulars as to the large Austrian libraries the reader is referred to the tables.

The libraries in the Hungarian kingdom are not included in this

report, and, as will be seen from the tables, are not very numerous. The most important of them are at Ruda-Pest.

Switzer-
land.

The public libraries of Switzerland have been very carefully registered by Dr. Ernest Hatz, as they existed in 1868. Altogether no less than 2066 libraries are recorded, four-fifths of these belong to the class of "bibliothèques populaires et écoles pour la jeunesse," and few are of literary importance. Only eighteen have as many as 30,000 volumes. The largest collection of books in Switzerland is the University Library of Basel, founded with the university in 1460. The monastic libraries of St Gall and Einsiedeln date respectively from the years 830 and 846, and are of great historical and literary interest.

ITALY.

Italy.

As the former centre of civilization, Italy is of course the country in which the oldest existing libraries must be looked for, and in which the richest and most valuable MSS. are preserved. The Vatican at Rome and the Laurentian Library at Florence are sufficient in themselves to entitle Italy to rank before most other states in that respect, and the venerable relics at Vercelli, Milan, and La Cava bear witness to the enlightenment of the peninsula in times when other nations were slowly taking their place in the circle of Christian polity. The local rights and interests which so long helped to impede the unification of Italy were useful in creating and preserving at numerous minor centres many libraries which otherwise would probably have been lost during the progress of absorption that results from such centralization as exists in England. In spite of long centuries of suffering and of the aggression of foreign swords and foreign gold, Italy is still rich in books and MSS., there are probably more books in united Italy than in any other country except France. When the Italian Government published its valuable report on "Biblioteche" in the *Statistica del Regno d'Italia* in 1866, a table of relative statistics was given, which professed to show that, while the number of books in Austria (2,408,000) was greater than the total contents of the public libraries in any one of the countries of Great Britain, Prussia, Bavaria, or Russia, it was surpassed in France (4,389,000) and in Italy (4,149,281), the latter country thus exhibiting a greater proportion of books to inhabitants than any other state in Europe, except only Bavaria. The opulent libraries of Rome and Venice had not yet become Italian, and were not included in the report.¹

Public
Libraries.

The public libraries (*biblioteche governative*) are under the authority of the minister of public instruction, and are subject to certain regulations finally agreed upon during the ministry of Signor Ruggiero Bonghi in 1876.² They are classed under the headings of (1) national libraries of Florence, Naples, Turin, Palermo, Vittorio Emanuele of Rome, the Brevin of Milan, and the Marciana of Venice; (2) the libraries of the universities of the first class—Bologna, Naples, Padua, Pavia, Pisa, and Rome; (3) those of the universities of the second class—Cagliari, Catania, Genoa, Messina, Modena, Parma, and Sassari; (4) those of academies and institutions of fine arts; the last, although under Government control, are ruled by special regulations of their own. Small collections are sometimes handed over to the local authorities, should this be considered desirable, and the state will take into its own hands the administration of provincial or communal libraries if necessary. The librarians and subordinates are divided into (1) prefects, librarians, and sub-librarians; (2) assistant librarians; (3) attendants, or book distributors; (4) ushers, &c. Those

¹ The *Statistica* describes 210 libraries, of which 164 were open to the public and 46 not accessible; 171 were general and 39 special libraries, the latter including 25 devoted to sacred theology, 11 to science and literature, and 8 to the fine arts. Tuscany, Sicily, and Emilia were the richest in books, the latter province alone containing one quarter of the whole number.

² See the "Regolamento delle Biblioteche Pubbliche," by Count Ugo Balzani, *Library Journal*, iv. pp. 138-47.

of class I constitute the "board of direction," which is presided over by the prefect or librarian, and meets from time to time to consider important measures connected with the administration of the library. The candidates for posts in classes 1 and 2 must possess certain scholastic qualifications and serve for a specified time as *aspirant* on probation. An important feature of the regulations consists of the scheme (unfortunately not yet in working order) which is eventually to supply Italy with a body of young librarians properly trained in all the theoretical and technical branches of their profession. Each library is to possess, alike for books and MSS., a general inventory or accession-catalogue, an alphabetical author-catalogue, and a subject-catalogue. When they are ready, catalogues of the special collections are to be compiled, and these the Government intends to print, together with the subject-catalogues of the MSS. Various other small registers are provided for. The sums granted by the state for library purposes must be applied to (1) salaries and maintenance; (2) binding and repairs; (3) purchase of books, MSS., &c. Books are chosen by a committee nominated by the minister, which, in the national libraries, includes the members of the council of direction. In other libraries two members only of the council form part of the committee. In the university libraries two-fifths of the expenditure is decided by the committee, and the remainder by a council formed by the professors of the different faculties. The rules for lending books and MSS. allow them to be sent to other countries under very special circumstances.

The *biblioteche governative* are now 32 in number, and annually spend about 150,000 lire in books. From the three sources of gifts, copyright, and purchases, their accessions in 1879 were 35,541, being 2187 more than the previous year. The number of readers is now gradually increasing. In 1879 there were 896,749, who made use of 1,164,853 volumes, showing an increase of 10,393 readers and 180,061 books as contrasted with the statistics of the previous year.³

The minister of public instruction has kept a watchful eye upon the literary treasures of the suppressed monastic bodies. In 1876 there were 1700 of these confiscated libraries, containing two millions and a half of volumes. About 660 of the collections were added to the contents of the public libraries already in existence; the remaining 1050 were handed over to the different local authorities, and served to form 371 new communal libraries, and in 1876 the number of new libraries so composed was 415.

The Biblioteca Vaticana stands in the very first rank Vatican among European libraries as regards antiquity, since from the middle of the 6th century we have evidence of the existence of a pontifical library at Rome; and Pope Zachary (d. 752), himself a Greek, is known to have added considerably to the store of Greek codices. The Lateran Library shared in the removal of the papal court to Avignon, and it was on the return of the popes to Rome that the collection was permanently fixed at the Vatican. Nicholas V. (d. 1455) may, however, be considered the true founder of the library, and is said to have added 5000 MSS. to the original store. Calixtus III. also enriched the library with many volumes saved from the hands of the Turks after the siege of Constantinople. So large a proportion of the printed books of the 15th century having been produced by the Italian presses, it is natural to expect that a great number of specimens may be found in the papal library, and, but for the wholesale destruction of books and MSS. during the sack of Rome by the duke of Bourbon in 1527, the

³ Lists of foreign accessions to the *biblioteche governative* are published by the minister of public instruction from time to time. In 1877 R. Nordstedt made proposals for a general catalogue of their contents, and issued a specimen of *Evangelica*.

Vatican Library would have been as rich in early printed literature as it is now rich in manuscripts. Sixtus V. erected the present building in 1588, and considerably augmented the collection. Gregory XV. received as a gift from Maximilian, duke of Bavaria, the library of the elector Palatine seized by Tilly at the capture of Heidelberg in 1622. The greater part of the library at Urbino, founded by Duke Federico, was acquired in 1655 by Alexander VII. for the sum of 10,000 scudi, and some of the famous palimpsests from the Benedictine monastery of Bobbio were also added to the treasures of the Vatican. After the death of Christina, queen of Sweden, her collection of books and manuscripts, formed from the plunder seized at Prague, Wurtzburg, and Bremen by her father Gustavus Adolphus, became by succession the property of the Ottoboni family, the head of which, Alexander VIII., in 1689 placed 1900 of the MSS. in one of the galleries. Clement VII. and Pius II. also enriched the Vatican with valuable manuscripts, including many Oriental. In 1740 Benedict XIV. united with it the Ottoboniana, and in the same pontificate the Marchese Aless. Capponi bequeathed his precious collections. Clement XIII. in 1758, Clement XIV. in 1769, and Pius VI. in 1775 were also important benefactors. For over two hundred years the history of the Vatican was one of unbroken prosperity, but it suffered a serious blow at the close of the 18th century, when MSS. dating before the 8th century, and the most choice artistic specimens, altogether to the number of 600, were carried off by the French to Paris in 1798. The greater part were, however, restored in 1815, and most of the Palatine MSS., which formed part of the plunder, ultimately found their way to the university of Heidelberg in 1816. Pius VII. acquired for the Vatican the library of Cardinal Zelada in 1800; Leo XII. was able to add the noble collection of fine art literature of Count Cloguarn in 1823; and Gregory XVI. also largely augmented the library. Pius IX. in 1856 added 40,000 volumes belonging to Cardinal Mai.

Few libraries are so magnificently housed as the Biblioteca Vaticana. The famous *Codici Vaticani* are placed in the *salone* or great double hall, which is decorated with frescoes depicting ancient libraries and councils of the church. At the end of the great hall an immense gallery, also richly decorated, and extending to 1200 feet, opens out from right to left. Here are preserved in different rooms the *codici Palatini*, *Regni*, *Ottoboniani*, *Capponiani*, &c. Most of the printed books are contained in a series of six chambers known as the *Appartamento Borgia*. The printed books only are on open shelves, the MSS. being preserved in closed cases.

The present official estimate of the number of printed volumes is about 220,000, including 2500 15th century editions, of which many are vulgus copies, 500 Aldines, and a great number of bibliographical rarities.¹ There are 25,000 MSS., of which 19,641 are Latin, 3613 Greek, 609 Hebrew, 900 Arabic, 460 Syriac, 78 Coptic, &c. Among the Greek and Latin MSS. are some of the most valuable in the world, alike for antiquity and intrinsic importance. It is sufficient to mention the famous Biblical *Codex Vaticanus* of the 4th century, the *Vergil* of the 4th or 5th century, the *Terence* equally ancient, the palimpsest *De Republica* of Cicero, conjectured to be of the 3d century, discovered by Cardinal Mai, and an immense number of richly ornamented codices of extraordinary beauty and costliness. The archives are apart from the library, and are quite inaccessible to the public; no catalogue is known to exist. Leo XII. has appointed a committee to consider what documents of general interest may expediently

be published, and a greater liberality in the use of them is said to be contemplated.

The Biblioteca Vaticana is now open from 8 to 12 every morning between November and June, with the exception of Sundays, Thursdays, and the principal feast days. Permission to study is obtained from the cardinal secretary of state. The want of proper catalogues for the use of readers is a great drawback. There are imperfect written lists (for the use of the librarians alone) of the printed books, and various catalogues of special classes of the MSS. have been published. New catalogues, however, are in course of preparation. The Oriental MSS. have been described by J. S. Assemani, *Bibliotheca orientalis Clementino-Vaticana*, Rome, 1719-28, 4 vols. folio, and *Bibl. Vat. cod. MSS. catalogus ab S. E. et J. S. Assemano relictus*, id., 1768-69, 3 vols. folio, and by Cardinal Mai in *Script. Vat. nova collectio*. The Coptic MSS. have been specially treated by G. Zoega, Rome, 1810, folio; and by F. G. Bonjourn, Rome, 1699, 4to. There are printed catalogues of the Capponi (1747) and the Cloguarn (1820) libraries.

Next in importance to the Vatican library is the Casanatense, other so called from the name of its founder, Cardinal Casanati (1700). Rome. It contains about 130,000 volumes of printed books, including a library of large number of 15th century impressions and early editions with woodcuts, as well as about 2500 MSS., amongst which are one of the 7th century and several of the 8th, 9th, and 10th centuries. They are carefully arranged in eleven rooms, the large central hall being one of the finest in Rome. Books are not allowed to be taken out of the reading-rooms, but admission is freely granted, and the annual number of readers is about 18,000. The subvention is a small one, but additions continue to be made, and the library is well administered. All the officials, in accordance with the founder's will, belong to the Dominican order. The incomplete catalogue of the printed books, prepared by A. Audifredi (Rome, 1761-88, 4 vols. folio), still remains a model of cataloguing.—The Biblioteca Vittorio Emanuele forms part of the Collegio Romano, and was made up from the old Jesuit library, enriched by accessions from a number of other suppressed institutions. It comprises a total of 860,000 volumes, with 5000 MSS., and is united to the Casanatense by a bridge. The entire edifice is spacious enough to contain a million of volumes, besides the Kircherian and other museums which are already located in it.—The Biblioteca Angelica possesses all the authentic works of the Gregorians in Latin, and the precious collections of Cardinal Passionei and Lances. Huetz.—The Biblioteca Alessandrina della R. Università di Roma, founded by Alexander VII., is considerably used by students: there were in 1876 67,000 readers. The greater part of the printed books formerly in the collection of the dukes of Urbino is now in this library.—The Biblioteca del Senato is very rich in collections of municipal history and statutes of Italian cities. The printed catalogue (1878) describes no less than 1067 statutes or volumes containing them, relating to 443 localities.—The Biblioteca Valliniana was founded by S. Filippo Neri, and contains some valuable manuscripts, including a Latin Bible of the 4th century attributed to Aleuin, and some incised writings of Beronius.—In 1877 Professor A. Sarti presented to the city of Rome his collection of fine-art books, 10,000 volumes, which was placed in charge of the Accademia di San Luca, which already possessed a good artistic library.—Of private libraries accessible to the public, we note the Biblioteca Barberina, including many rare editions with valuable autographs, but especially remarkable for its MSS.; these were chiefly collected by Cardinal Fr. Barberini, the nephew of Urban VIII., and comprehended the letters and papers of Galileo, Bembo, and Bellarmine, the reports on the state of Catholicism in England in the time of Charles I., and a quantity of incited materials for the history of the Stanzas. A catalogue was published at Rome in 1681, 8 vols. folio.—The Corsiniana, founded by Clement XII. (Lorenzo Corsini), is also a private library; it is rich in incunabula, and includes one of the most remarkable collections of pictures in Italy, the series of Marco Antonio being especially complete.—The library of the Collegium de Propaganda Fide was established by Urban VIII. in 1623, and in 1867 the rector Andrea Bonvicini obtained permission to preserve in it prohibited books. It was

¹ See *Collegio Romano, Discorso di Ruggiero Bonghi*, Rome, 1876.

² Signor R. Michoud produced a catalogue of the other three Oriental in 1877. The Casanatense, Vat. Emanuele, Angelica, Alessandrina are Governmental, and in 1878 the minister of public instruction published a catalogue of the Oriental MSS. in the three last. The Oriental MSS. of the other *Bibliotheca generalis* will be treated in subsequent volumes.

¹ The books have never been actually counted, and this estimate has been reduced by some persons to half the number.

destroyed by the French army in 1798, and owes its present richness almost entirely to testamentary gifts, among which may be mentioned those of Cardinals Borgia, Colonna, and Estro. It is a private collection for the use of the congregation and of those who belong to it, but permission may be obtained from the superiors. There are at least 15 libraries in Rome which are more or less accessible to the public. One is now in course of formation which will include everything relating to the emancipation of Italy.

Subiaco.

At Subiaco, a few miles from Rome, the library of the Benedictine monastery of Santa Scolastica is not a very large one, comprising only 6000 printed volumes and 400 MSS., but the place is remarkable as having been the first seat of typography in Italy. It was in this monastery that Schweyheilm and Farnart, fresh from the dispersion of Fust and Schoeffer's workmen in 1439, established their press and produced a series of very rare and important works which are highly prized throughout Europe. The Subiaco Library, although open daily to readers, is only visited by students who are anxious to behold the cradle of the press in Italy, and to inspect the series of original editions preserved in their first home.

National
libraries
Florence.

The great national libraries are as follows:—

The Biblioteca Nazionale di Florence, formed from the union of Magliabechi's library with the Palatina, the largest under Government control in Italy. The Magliabechi collection became public property at his death in 1714, and with the accessions made from time to time, held an independent place until 1862, when the Biblioteca Palatina (formed in 1816 from the old Pitti Library and the collections of Poggiali and Kozovsky) was incorporated with it. An old statute, by which a copy of every work printed in Tuscany was to be presented to the Magliabechi Library was formerly much neglected, but has been maintained rigorously in force since 1860. There are many valuable autograph originals of famous works in this library, and the MSS. include the most important extant copies of Dante and later poets, as well as of the historical works of Villani, Machiavelli, and Guicciardini. Amongst the printed books is a very large assemblage of rare early impressions, a great number of the *Rappresentazioni* of the 16th century, at least 200 books printed on vellum, and a copious collection of municipal histories and statutes, of tests of geographical and topographical maps. The MSS. portion, 25 in number, are for the most part of great importance; the oldest is dated 1417, and several seem to be the original charts executed for Sir Robert Dudley (duke of Northumberland) in the preparation of his *Arconte del Mare*. The annual increment of books in this library is about 15,000, and is open freely to the public, and about 50,000 readers annually make use of it. About 80,000 printed volumes and 2500 MSS. are consulted annually, not including some 1600 books and 80 MSS., which are lent out yearly to certain students.—The Biblioteca Nazionale at Naples, though only opened to the public in 1804, at the suggestion of this city, the nucleus from which it developed was the collection of Cardinal Seripando, which comprised many MSS. and printed books of great value. Acquisitions came in from other sources, especially when in the year 1846 many private and conventual libraries were thrown on the Neapolitan market.¹ The Biblical section is rich in volumes, commencing with the Mainz Bible of 1462, printed on vellum. Other special features are the collection of *testi di lingua*, that of books on volcanoes and that of works printed at famous presses, particularly those executed by the typographers of Naples. The MSS. include a palimpsest containing writings of the 8d, 9th, and 10th centuries under a grammatical treatise of the 8th, 2 Latin poetry of the 9th century, over 50 Latin Bibles, and a great number of illuminated books with miniatures. There are more than 40 books printed on vellum in the 16th and 17th centuries, including a fine first Homer. There are several MS. maps and portolan, one of them dating from the 14th century. About 16,000 readers use this library, consulting some 140,000 books yearly.

Naples.

Milan.

The Biblioteca Nazionale di Milano, better known as the Brera, founded in 1770 by a decree of the empress Maria Theresa, consists of 168,138 printed volumes and 3648 MSS., with a yearly increment of about 6000 volumes, with miniatures representing the advance of the amount to 46,000. It comprises nearly 2500 books printed in the 16th century (including the rare *Monia Santo di Dio* of Bizzini, 1477), 918 Aldine impressions, and a xylographic *Bibbia Pauperum*. Amongst the MSS. are an early Dante and autograph letters of Galileo, some poems in Tasso's autograph, and a fine series of illustrated service-books, with miniatures representing the advance of Italian art from the 12th to the 16th century. These were formerly

Palermo.

Turin.

in the Certosa at Parma.—The Biblioteca Nazionale di Palermo, founded from the Collegio Massimo of the Jesuits, with additions from other libraries of that suppressed order, is rich in 16th century books, which have been elaborately described in a catalogue printed in 1876, and in Aldine and bibliographical curiosities of the 16th and following centuries.—The Biblioteca Nazionale di Turin is extensively used by readers, whose annual

number amounts to 120,000. The majority of the books are works for scientific study, but amongst them are several rarities, comprising a Soderini MS. of the 5th century, the celebrated MS. of the *De Institutione* (on which the assignment of its authorship to Cicero is founded,—see Keuvrgh), and several productions of the earliest German and Italian printers.—The Biblioteca Marciana, or library of St Mark at Venice, was founded Venice in 1802 by a donation of MSS. from the famous Petrusch (most of them now lost), and constituted as a library by Cardinal Bassano in the 16th century. It is open daily, and is used by about 4000 readers annually. The precious contents include Greek MSS. of great value, of which more than 1000 were given by Cardinal Bessarion, important MS. collections of works on Venetian history, rare manuscripts, and a great number of volumes, unique or exceedingly rare, on the subject of early geographical research. Amongst the MSS. is a Latin Homer in the autograph of Boisson, an invaluable copy of the laws of the Lombards, and the autograph MS. of Sargi's *History of the Council of Trent*. Since the fall of the republic and the suppression of the monasteries afterwards, a great many private and conventual libraries have been incorporated with the Marciana.

Of the remaining libraries under Government control it is unnecessary to notice the Biblioteca della Università at Bologna, since founded in 1719 by Count Luigi F. Marzighi or Marsili. The library MSS. comprise a rich Oriental collection of 547 MSS. in Arabic, 173 in Turkish, and several in Persian, Armenian, and Hebrew. Amongst the Latin codices is a *Lectiones* of the 6th or 7th century. The other noteworthy articles include a copy of the Armenian gospels (12th century), the *Arriani*, with miniatures dated 1194, described in Montfaucon's *Diploma Gallicum*, and some unpublished Greek texts. Amongst the Italian MSS. is a not uninteresting of municipal histories. Mazzuchini, for a long time the custodian here, and his own collection of books, has been incorporated in the library, which is remarkably likewise for the number of early editions and Aldines which it contains. It possesses the Mainz Latin Bible dated 1462; the *Lectiones* and *Augustine De Civitate Dei* printed by Schweyheilm and Farnart, the Foligno Dante of 1474, and a copy of Henry VIII.'s *despatches*. The other noteworthy articles include a copy of the drawings by Agostino Caracci as another special feature of worth. The Manfredi palace, in which the library is arranged, is a fine building begun in 1714 and finished in 1744. The grand hall with its fine furniture is valued more than particular attention. The library is open to the public; and yearly a number of readers is about 25,000, and of books consulted 40,000.²

Of the remaining Government libraries the following may be named.—The Biblioteca del Monastero della S. Trinità, at La Cava dei Treveri in the province of Salerno, is situated the Biblioteca dell' Archivio Capitulare which is the most ancient library in the Italian kingdom, its foundation being said to be contemporaneous with that of the Benedictine abbey itself (beginning of the 11th century). It only contains some 10,000 volumes, but these include a number of MSS. of very great rarity and value, ranging from the 8th to the 14th century. Amongst these is the celebrated *Codex Legum Longobardorum*, dated 1004, besides a well-known geographical chart of the 12th century, over 100 Greek MSS., and about 1000 charters beginning with the year 840, more than 500 of which belong to the Lombard and Norman periods.—At Florence the Marcioni Library, founded in 1752, is remarkable for its series of early woodcuts and metal engravings. The number of these and of original drawings by the old masters amounts to 80,000 pieces.—At Modena is the famous Biblioteca Palatina, sometimes called *Modena* the Biblioteca Estense from having been founded by the Este family at Ferrara in 1358; it was transferred to Modena by Cesare D'Este in 1698. Muratori, Zaccaria, and other great librarians here, and made good use of the treasures of the library. It is particularly rich in early printed literature and valuable codices.—The oldest library at Naples is the Biblioteca Brancacciana, with many valuable MSS. relating to the History of Naples. Two palimpsests by Constantine the Great have been found in 1878 by Cardinal J. M. Brancaccio.—The Regia Biblioteca di Parma, founded definitively in 1770, owes its origin Parma to the grand-duke Philip, who employed the famous scholar Reisch to organize it. It is now a public library containing 218,494 volumes, including 4000 MSS., with an annual increment of nearly 1000 volumes. Amongst its treasures is De Rossi's magnificent collection of Biblical and rabbinical MSS.

Chief among the great libraries not under Government control comes the world-famed Biblioteca Mediceo-Laurenziana at Laurentine, formed from the collections of Cosimo the Elder, Pietro de' Medici, and Lorenzo the Magnificent (who bequeathed the remainder of the family after the expulsion of the Medici from Florence, and were repurchased by Cardinal Giovanni afterwards Leo X.). It was first constituted as a public library in Florence by

¹ A palimpsest by the present chief librarian, Vito Bonazzi, Naples, 1874, gives many useful details, although he there overstates the number of MSS. as 10,000 (there may be some confusion between volumes and works).

² Notices of other libraries of this class will be found in the table.

Clement VII, who charged Michelangelo to construct a suitable edifice for its reception. It was opened to the public by Cosimo I in 1571, and has ever since gone on increasing in value, the accessions in the 18th century alone being enough to double its former importance. The printed books it contains are probably no more than 30000 in number, but are almost all the highest rarity and the most interesting. It is the collector's library, and contains up to about 7000 autographs, which gives it their chief importance to this library. They comprise some of its most valuable codices in the world—the famous *Vulgar* of the 4th or 5th century, *Justinian's Pandects* of the 7th, a *Homær* of the 10th, and several other very early Greek MSS. of the 11th and 12th centuries, as well as some of the best handwritings of Petrarch, about 100 copies of *Don Quixote*, *Desnoyers*, copied by a contemporary from Boccaccio's own MS, and Cellini's MS of his autobiography. Bandini's catalogue of the MSS comprises 18 vols folio, printed in 1764–78.—At Genoa the *Biblioteca Franeschini*, founded about 1770 for the purpose of collecting the MSS of the *Franceschini* family, has a fine humanæ library, printed and unprinted, for the use of graduates.

Ambrosiana. The famous Biblioteca Ambrosiana at Milan was founded in 1809 by Cardinal Fed. Borromeo. It contains 184,000 printed volumes and 8100 MSS. Amongst the MSS are a Greek Pentateuch of the 5th century, the famous *Peshito* and Syro-Hexaplar from the Nitrian convent of St Maria Deipara, a Josephus written on papyrus, supposed to be of the 5th century, several palimpsest texts, including an early *Platine*, and *St Jerome's* commentary on the *Psalms* in a volume of 7th century execution, full of contemporary glosses in Irish, Gothic fragments of *Ulfilas*, and a *Virgil* with notes in Petrus's handwriting.¹ Noteworthy amongst the MSS is the *Mariner's Eusebius* of 1471, as well as the *Virgil* of 1470 (Venice), and the *editio princeps* of Isocrates, both printed on vellum. Cardinal MSS, *ms*

cups of coffee; and the pastiche here is by 1879 Professor C. Managatti, president of the "Biblioteca Europea," consisting of 2500 volumes, 300 maps, and 6000 pieces, all relating to the literatures and linguistics of European countries.—The Latin and Trivulzio libraries should not pass without mention here, although they are private and inaccessible without special permission. The former is remarkable for its collection of books and manuscripts with notes written in the hands of 1481 twenty deacons by Paolo Bandinelli. The latter is rich in MSS with miniature of the finest and rarest kind, and in printed books of which many are unique or nearly so. It consists of 70,000 printed volumes.—The foundation of the monastery of Monte Cassino is due to St Benedict, who arrived there in the year 529, and established the prototype of monasteries in western Europe. He brought with him a few manuscripts, four or five of which are still to be seen. The library of printed books now extends to about 20,000 volumes, chiefly relating to the theological sciences, but including some rare editions. A collection of the books belonging to the monks is in course of formation ; it contains about the same number of volumes as the great glory of the Vatican—namely, the entire contents of the library of the Vatican. This includes 80,000 or 40,000 latins, diplomas, charters, and other documents, besides 100,000 MSS dating from the 6th century downwards. The latter comprehend some very early Bibles and important codices of patristic and other medieval writings. There are good written catalogues, and a calendar is now being published, *Bibliotheca Cassinensis*, of which I have procured a copy. These publications enjoy no special revenues, and their expenses entirely to donations.—At Ravenna the Biblioteca Classense has a 10th century code of Aristophanes and two 14th century codes of Dante. Here are also the autograph correspondences of Muratori, and many unpublished letters of modern writers.—At Vercelli the Bibliotheca Gelfi Alessandrini Covattone, the most valuable one, has been assigned to the certain date, but will be referred to the early days of our barbarous conquerors of Italy had become Christianised, comprises nothing but MSS, all of great antiquity and value. Among them is an Evangelium in Russian in Latin, supposed to be of the 4th century; also the famous code containing the Anglo-Saxon *Lomlives* which have been published by the *Zellio Society*.—The public library at Verona is the richest in the north of Italy, the invaluable state paper records of the Venetian republic.

Brussels. The national library of Belgium is the Bibliothèque Royale at Brussels, of which the basis may be said to consist of the famous Bibliothèque des Ducs de Bourgogne, the library of the Austrian sovereigns of the Low Countries, which had gradually accumulated

³ Ceriani has published many of the unique treasures of this collection in his

* This, as well as the Brera library, is exhaustively described in *ON Italian antiquities, letters, and artists of Milan*, published by the Società Storica Lombarda in 1880; a special treatise on the Brera was published in 1872 by the librarian G. Sacchi. See also Roschi, *De origine et statu Bibliothecae Ambrosianae*, 1873.

* A most interesting & accurate account of the history of this library may be read in the introduction to *Catalogue des MSS. de la Bibliothèque royale des arts de Paris*, by M. Marchal, Brussels, 1842, 4 vols. etc.

Scaliger, Isaac Voss, Heubner, and Heuserius. The MSS comprehend many of the most important; the Oriental codices number 2400. The library of the Society of Netherland Literature has been placed here since 1877; this is rich in the national history and literature. The Arabic and Oriental MSS. known as the Legation Warmermann are of great value and interest, and the collection of maps bought in 1870 by J. J. Boel Nijmhus is also noteworthy. The library is contained in a building which was formerly a church of the Bégimes, adapted in 1860 somewhat after the style of the British Museum. The catalogues (one alphabetical and one classified) are on slips, the titles being printed. A catalogue of books and MSS was printed in 1716, one of books added between 1814 and 1817 in 1846, and a supplementary part of MSS. only in 1860. A catalogue of the Oriental MSS was published in 6 vols., 1851-77.

Utrecht. The University Library at Utrecht dates from 1628, when certain conventual collections were brought together in order to form a public library, which was shortly afterwards enriched by the books bequeathed by Hub Bachelius and Kv. Polius. Upon the foundation of the university in 1636, the town library passed into its charge. Among the MSS. are some interesting older MSS and the famous "Utrecht Psalter," which contains the oldest text of the Athanasian creed. The last edition of the catalogue was in 9 vols. folio, 1854, a supplement in 1845, index from 1846-55 in 8vo, and additions 1856-70 in 2 vols. 8vo. The titles of accessions are now printed in sheets and pasted down for insertion.

Amsterdam. The basis of the University Library at Amsterdam consists of a collection of books brought together in the 16th century and preserved in the Nieuwe Kerk. At the time of the Reformation in 1578 they became the property of the city, but remained in the Nieuwe Kerk for the use of the public till 1632, when they were transferred to the Athenaeum. Since 1877 the collection has been known as the University Library, and in 1881 it was removed to a building designed upon the plan of the new library and reading-room of the British Museum. The library includes the best collection of medical works in Holland, and the Bibliotheca Rosenbachiana of Hebrew and Talmudic literature is of great fame and value; a catalogue of the last was printed in 1875. The libraries of the Dutch Geographical and other societies are preserved here. A general catalogue was issued in 6 vols. 8vo, Amsterdam, 1858-77; one describing the bequests of J. de Bosch Kemper, E. J. Poegeler, and P. W. Rive, in 8 vols. 8vo, 1878-79; a catalogue of the MSS. of Professor Mall was published in 1880, and one of those of P. Camper in 1881.

Denmark, Norway, and Sweden

Copenhagen. The commencement of the admirably managed national library of Denmark, this great Royal Library at Copenhagen, may be said to have taken place during the reign of Christian III. (1533-58), who took pride in importing foreign books and choice MSS., but the true founder was Frederick III. (1648-70); to him is mainly due the famous collection of Icelandic literature and the acquisition of Tycho Brahe's MSS. The present building (in the Christiansborg Castle) was commenced in 1667. Among notable accessions may be mentioned the collections of O. Reizner, the count of Darneskjöld (3000 volumes and 600 MSS.) and Count de Thott; the last bequeathed 6389 volumes printed before 1681, and the remainder of his books, over 100,000 volumes, were eventually purchased. In 1788 the library was opened to the public, and it has since remained under state control. Two copies of every book published within the kingdom must be deposited here. The manuscripts and block books form an important series. There is a general classified catalogue in writing in 295 folio volumes for the use of readers; and an alphabetical one on slips arranged in boxes for the officials. A good catalogue of the De Thott collection was printed in 13 vols. 8vo, 1789-95; a catalogue of the French MSS. appeared in 1844. Of Oriental MSS., 1846; of the Danish collection, 1875, 8vo. Annual reports and accounts of notable MSS. have been published since 1864. There were 7000 additions in 1880.

The University Library, founded in 1459, was destroyed by fire in 1728, and re-established shortly afterwards. A copy of every Danish publication must be deposited here. The MSS. include the famous Arns-Magnæsen collection (see vol. xi. p. 628).

Christiania. The chief library in Norway is the University Library at Christiania, established at the same time as the university, September 2, 1311, by Frederick II., with a donation from the king of many thousands of duplicates from the Royal Library at Copenhagen, and since augmented by important bequests.

Stockholm. The Royal Library at Stockholm was first established in 1656. The original collection was given to the university of Upsala by Gustavus II., that formed by Christina at the fall of Sweden, and the library brought together by Charles X. was destroyed by fire in 1697. The present edifice was organized shortly afterwards. The Bonatzleria-Ringsström Library, 14,500 printed volumes and 1200 MSS., rich in materials for Swedish history, is now annexed to it. Natural history collections and mathematical are left to other

libraries. Among the MSS. the *Codex Aureus* of the 6th or 7th century, with its interesting Anglo-Saxon inscription, is particularly noteworthy. The catalogues are in writing, and are both alphabetical and classified. Printed catalogues have been issued of portions of the MSS. The present building was opened in 1882.

The University Library at Upsala was founded by Gustavus Upsala Academicus in 1699, from the remains of several convent libraries; he also provided an endowment. The MSS. chiefly relate to the history of the country, but include the *Codex Argenteus*, containing the Gothic gospels of Ulfilas. The general catalogue is in writing. A catalogue was printed in 1814, special lists of the foreign accessions have been published each year from 1860, the Arabic, Persian, and Turkish MSS. are described by C. J. Tornerberg, 1848. The library at Lund dates from the foundation of the university in 1668, and was based upon the old cathedral library. The MSS. include the De la Gardie archives, acquired in 1849.

Spain and Portugal

The chief library in Spain is the Biblioteca Nacional (formerly Madrid the Biblioteca Real) at Madrid. The printed volumes number 400,000 volumes, with 200,000 pamphlets; the accessions in 1880 amounted to 25,840 volumes. Spanish literature is of course well represented, and, in consequence of the numerous accessions from the libraries of the suppressed convents, the classes of theology, canon law, history, &c., are particularly complete. The number of bibliographical rarities was largely increased by the acquisition of the valuable collection formed by the well-known bibliographer Don Luis de Usar. There are 30,000 MSS., contained in 10,000 volumes and bundles; they include some finely illuminated codices, historical documents, and many valuable autographs. The collection of prints extends to 124,000 pieces, and was principally formed from the important series bought from Don Yáñez Cardenas in 1855. In 1830 54,874 books were issued to 51,946 readers. The annual revenue is only £1800. The printed books have one catalogue arranged under authors' names, and one under title, the departments of music, maps and charts, and prints have subject-catalogues as well. There is a general index of the MSS., and special catalogues of the Greek and Latin codices and genealogical documents. The first (and only) volume of a printed catalogue of the Greek MSS. appeared in 1769. This cannot be made as most valuable and well arranged. Of the other Madrid libraries (see the tables) it is enough to mention the Biblioteca de Academia de Historia (20,000 volumes and 1500 MSS.), which contains some printed and MS. Spanish books of great value, including the well-known Salazar collection.—The history of the library of the Escorial has been given at vol. viii. p. 541. Escorial. In 1603, before the invasion, the Escorial is estimated to have contained 80,000 printed volumes and 3400 MSS.; Joseph removed the collection to Madrid, but when it was returned by Ferdinand 10,000 volumes were missing. There are now 32,142 printed volumes, with 538 Greek, 1905 Arabic, 73 Hebrew, and 2050 Latin MSS. The Arabic MSS. have been described by M. Casiri, 1760-70; and a catalogue of the Greek codices by Müller was issued at the expense of the French Government in 1848. There is an imperfect writer's catalogue of the printed books, and the present librarian is now engaged upon a catalogue of the Latin MSS. Permission to study at the Escorial, which is one of the royal private libraries, must be obtained by special application.

Among the libraries of Portugal the Biblioteca Nacional at Lisbon. Lisbon naturally takes the first place. In 1841 it was largely increased from the monastic collections, which, however, seem to have been little cared for according to a report prepared by the principal librarian three years later. There are now said to be 200,000 volumes of printed books, among which theology, canon law, history, and Portuguese and Spanish literature largely predominate. The MSS. number 8416, including many of great value. There is also a cabinet of 40,000 coins and medals.—The Bibliotheca de Academia, founded in 1780, is preserved in the suppressed convent of the Ordem Terceira da Penitência. In 1836 the Academy acquired the library of that convent, numbering 30,000 volumes, which have since been kept apart. The Archive Nacional, in the same building, contains the archives of the kingdom, brought here after the destruction of the Torre do Castelo during the great earthquake.

The Bibliotheca Publica Municipal at Oporto is the second largest Oporto. In Portugal, although only dating from July 8, 1858, the anniversary of the proclamation of D. Pedro, and when the memorable siege was still in progress; from that date to 1874 it was styled the Real Bibliotheca do Porto. The regent (ex-emperor of Brazil) gave to the town the libraries of the suppressed convents in the northern provinces, the municipality undertaking to defray the expense of keeping up the collection, but only £150 is yearly spent on books and bindings, and £250 on salaries. Recent accessions consist

¹ Guichard, *Les Bibliothèques de Madrid et de l'Escorial; notices et extraits des MSS. qui composent l'histoire de Philippe, Bruneau, 1876, 4to.* Ch. Guizot, *Essai*

mainly of Portuguese and French books. The important Caracoe collection is described in a printed catalogue, Oporto, 1850. A notice of the MSS. may be found in *Catálogo dos MSS da B. Publica do Rio de Janeiro*, by H. da Cunha Rivara, Lisbon, 1850-70, 3 vols. folio, and the first part of an *Index preparatus ad Catalogo dos Manuscriptos* was produced in 1850.

Russia

St. Petersburg. The Imperial Public Library at St. Petersburg is the third largest library in the world, and now claims to possess 1,000,000 printed volumes. The commencement of this magnificent collection may be said to have been, the books sent by the Czar Peter during his invasion of Courland in 1714, the library did not receive any notable augmentation, however, till the year 1795, when, by the acquisition of the famous Zolnaki collection, the Imperial Library suddenly attained a place in the first rank among great European libraries. The Zolnaki Library was formed by the Polish count Joseph Zolnaki, who collected at his own expense during forty-three years no less than 200,000 volumes, which were added to by his brother Andrew, bishop of Cracow, by whom in 1747 the library was thrown open to the public. At his death it was left under the control of the Jesuit College at Waisaw, on the suppression of the order it was taken care of by the Commission of Education, and finally in 1795 it was transferred by Suwaroff to St. Petersburg as a trophy of war. It then extended to 260,000 printed volumes and 10,000 MSS, but in consequence of the withdrawal of many useful and illustrated works to enrich other institutions, hardly 238,000 volumes remained in 1810. Literature, history, and theology formed the main features of the Zolnaki Library, the last class alone amounted to one-fourth of the whole number. Since the commencement of this century, through the liberality of the sovereigns, the gifts of individuals, careful purchases, and the application of the law of 1810, whereby two copies of every Russian publication must be deposited here, the Imperial Library has attained its present extensive dimensions. Nearly one hundred different collections, some of them very valuable and extensive, have been added from time to time. They include, for example, the Tolstoi Slavonic collection (1800), Tischendorf's MSS (1858), the Dolgorouki Oriental MSS (1859), and the Karamzin collection (Karamzin collection (1859-65), the libraries of Adelung (1858) and Tobler (1877), that of the Slavonic scholar Jungmann (1856), and the national MSS. of Karamzin (1867). This system of acquiring books, while it has made some departments exceedingly rich, has left others comparatively meagre.

The library was not regularly opened to the public until 1814; it is under the control of the minister of public instruction. In the printed book department the yearly average of readers is now 107,000, and of books consulted 235,800. The annual grant from the treasury is 75,174 roubles; an income of 1848 roubles is derived from other sources. The official estimate of the number of printed books is 1,000,000 volumes, with 19,059 maps and 74,000 prints and photographs. The yearly accessions amount to about 50,000. The Russian books number 100,000 and the Russian 80,000 volumes, the Arian and Elsevier form a nearly perfect collection, and the innumerable sea numerous and very meticulously cared for.

The manuscript include 26,000 codices, 41,840 autographs, 4689 charters, and 576 maps. The glory of this department is the celebrated *Codex Bezae Cantabrigiae* of the Greek Bible, brought from the convent of St. Catherine on Mount Sinai by Tischendorf in 1859. Other important Biblical and patristic codices are to be found among the Greek and Latin MSS, the Hebrew MSS include some of the most ancient that exist, and the Samaritan collection is one of the largest in Europe; the Oriental MSS. comprehend many valuable texts, and among the French are some of great historical value.

The general catalogues are in writing, but the following special catalogues of the printed books have been published—the *Voltaire* collection of early printed Russian books, 1829; the *Altdine*, 1854, the *Elzevir*, 1865, and another in 1864, by C. F. Walther; editions printed during the reign of Peter the Great, by Bytchkoff, 1847; the foreign books relating to Peter the Great by P. Minckoff, 1872; and the Russian, vol. 1, 1873. Lists of the foreign books have been issued since 1863, and the *Comptes Rendus* published since 1850 contain notices of the most important acquisitions.

The following catalogues of the MSS. are in print—the *Tolstoi Slavonic collection*, 1826; *Dom's catalogue of the Oriental MSS*, 1832; old German, 1850; the Greek, by Murik, 1854, the *Elzevir*, 1865; the *Hebrew MSS*, 1875, *Slavonic and Russian miscellanea*, parts 1 and 2, 1878-80.

The nucleus of the library at the Hermitage Palace was formed by the empress Catherine II., who purchased the books of the MSS. of Voltaire and Diderot. In the year 1801 the collection amounted to 160,000 volumes, of which nearly all not relating to the history of art were then transferred to the Imperial Library.

Moscow. The second largest library in Russia is contained in the public museum at Moscow. The class of history is particularly rich, and

Russian early printed books are well represented. The MSS. number 5000, including many ancient Slavonic codices and historical documents of value. One room is devoted to a collection of Masani MSS, which comprehend the archives of the lodges in Russia between 1810 and 1821. There is a general alphabetical catalogue in writing, the catalogue of MSS has been printed, as well as those of some of the special collections.

For other Russian libraries see the tables.

India, China, and Japan.

Of Indian libraries it is sufficient to notice those that have India.

Superintendent for Oriental Letters. At Calcutta the Sanskrit college has 1669 printed Sanskrit volumes and 3799 Sanskrit MSS, some as old as the 14th century, there is also a large collection of Jan. MSS. A catalogue is now being prepared for publication.—The Arabic library attached to the Arabic department of the Madras was founded about 1781, and now includes 731 printed volumes, 148 original MSS and 151 copies, the English library of the Anglo-Persian department dates from 1864, and extends to 8254 volumes.—The library of the Asiatic Society of Bengal was founded in 1784, and now contains 15,000 printed volumes, chiefly on Eastern and philological subjects, with a valuable collection of 9500 Arabic and Persian MSS. A catalogue is now passing through the press.

At Bombay the library of the Bombay branch of the Royal Asiatic Society, established in 1804 as the Literary Society of Bengal, is now an excellent general and Oriental collection of 40,000 printed volumes and 200 MSS, described in a printed catalogue of 1875. The Moolla Faizul Library was bequeathed for public use by Moolla Faizul, head priest of the law of the Kodri sect, in 1831, and consisted chiefly of MSS. in Arabic and Persian on history, philosophy, and astronomy, some additions of English and Gujarati works have been made, as well as of European books on Zoroastrianism. A catalogue has been printed.

The library of Tanjore Sahib, consisting of 2000 MSS, fell into the hands of the British, and a descriptive catalogue of them by Charles Stewart was published at Cambridge in 1809, 4to. A few were presented to public libraries in England, but the majority were placed in the college of Fort William, then recently established. The first volume, containing Persian and Hindustani poetry, of the *Catologue of the Libraries of the King of Oudh*, by A. Sprenger, was published at Calcutta in 1854. The compiler shortly afterwards left the Indian service, and no measures were taken to complete the work. On the annexation of the kingdom in 1855 the eking is believed to have taken some of the most valuable MSS. to Calcutta, but the largest portion was left behind, by the King of Oudh, to be used as the books were used to block up windows, &c., and those which were not destroyed were abandoned, and plundered by the soldiers. Many were burnt for fuel, a few, however, were rescued and sold by auction, and of these some were purchased for the Asiatic Society of Bengal.

Perhaps the most remarkable library in India is that of the raja of Tanjore, which dates from the end of the 18th or beginning of the 17th century, when Tanjore was under the rule of the Taluqa Naika, who collected Sanskrit MSS written in the Telugu character. In the 18th century the Marathas conquered the country, and since that date the library increased but slowly. By the greater portion of the store was acquired by Sheroobahadur Raja during a visit to Bonares in 1820-30, his successor Sivaji added a few, but of inferior value. There are now about 18,000 MSS. written in Devanagari, Nagari, Telugu, Kannada, Grantha, Malayalam, Bengali, Pali, or Kashmiri, and Uru; 8000 are on palm leaves. Dr. Burnell's printed catalogue describes 19,575 articles.

Thanks to the enlightened policy of the Government of India, we are beginning to know much more respecting native literatures than was possible a few years ago, and since 1868 a yearly sum of 24,000 rupees has been granted to carry on the work of searching for Sanskrit MSS. The first part of a list of these in private lands in southern India has been published by Dr. G. Oppert; it contains a description of 8376 MSS, and another volume is in course of preparation. Dr. Buhler, in his investigation of Sanskrit's library at Bombay, found 800 MSS. of great antiquity, six dating from the beginning of the 13th century. A resident has examined the Samghavina Peda Library in Pithan, and a catalogue has been prepared for printing. A copy of the oldest Sanskrit dictionary, the *Sanskrit Kosha*, of which only one other copy (at the Bodleian) is known, was found here. Dr. Buhler also obtained 490 Sanskrit MSS. for the Government. Inquiries made in Bihar have not met with much result. Notices of Sanskrit MSS in the presidency of Bengal have been prepared under the direction of Dr. Rajendralal Mitra; seven fasciculi (1000 pp.) have been printed, describing 842 articles. The same scholar has also printed a catalogue (746 pp.) of the library of the maharaja of Bikaner, describing 2000 Sanskrit MSS and his analysis of the Sanskrit Buddhist literature of Nepal will shortly be published. The total number of Sanskrit MSS. acquired in this presidency in 1861, some of which are new to Europeans. Two catalogues of 180 Sanskrit MSS. discovered in the North-Western Provinces and Oudh during 1878-80 have been projected,

and the following libraries (containing many important texts) of the Punjab have been acquired.—That of Pandit Rikhkoshia, of 600 books, Pandit Jyoti Datta Pressda, 2690 MSS., the largest collection in the province, and Pandit Dularam, 430 MSS. The efforts of Dr. Fockhammer will probably bring to light many valuable Sanskrit MSS., both in Upper and Lower Burma.

The Balfour Library at Singapore was established as a proprietary institution in 1844, taken over by the Government in 1874, and given legal status by an ordinance passed in 1878. It now contains 11,000 volumes in general literature, but books relating to the Malay Peninsula and archipelago have been made a special feature, and since the acquisition of the collection of J. R. Logan in 1879 the library has become remarkably rich in this department.

The library of the Genootschap van Kunsten en Wetenschappen at Batavia contains books printed in Nederlandsch India, works relating to the Indian Archipelago and adjacent countries, and the history of the Dutch in the East. There are now 30,000 printed volumes and 1630 MSS., of which 219 are Arabic, 445 Malay, 303 Javanese, 60 Batak, and 517 on lontar leaves in the ancient Kawi, Javanese, and Bali languages, &c. The last edition of the catalogue appeared in 1877, printed catalogues of the Arabic, Malay, Javanese, and Kawi MSS. have also been issued.

China.—The Great Imperial Library was founded by K'iu Lung, 18th century, and from its catalogue which has been issued up to date have been counted about 12,000 works, extending to 158,000 volumes. There are now many provincial libraries in China, and the chief Buddhist monasteries also possess collections of books.

Japan.—The library of the Tokio Zu (municipality of Tokio) at Leido, in the old Chinese university, contains 65,000 Chinese and Japanese volumes, and 5900 European, principally English and Dutch. The reading-room is supplied with native daily papers, and the chief foreign periodicals. The library is open for purposes of reference, and books may be borrowed by special permission. The Asakusa Library, now occupying the former fireproof rice storehouses of the shogun, is one of the oldest in the country, and is reported to contain 143,000 volumes, including many ancient books and MSS., an entrance fee of about 3d is charged here. The Imperial University has a good collection of European and Japanese sciences and general literature. The libraries of the large temples often contain rare books of value to the philologist, and many of the leading towns throughout the country are provided with free libraries. Lending libraries of native and Chinese literature have existed in Japan for many very early times.

British Colonies.

Of such libraries as may be found in the British colonies there are very few that call for particular mention here.

The largest collection of books in Canada is the library of parliament at Ottawa. Though founded in 1815, it contained very few books until 1841, when the two libraries of Upper and Lower Canada were joined. After being destroyed by fire, the library was re-established in 1855, chiefly for parliamentary use. It now contains 100,000 volumes, and is open to the public except when parliament is sitting. Books are lent out. The main library is a handsome octagonal apartment with beautiful carved work in Canadian white wood.

In the South African Public Library at Capetown, which was established in 1818, there are 39,000 volumes, including the collection bequeathed by Sir George Grey, comprising, besides MSS. and early printed books, an unrivalled collection of works in the native languages of Africa, Australia, &c. The library is open to any respectable person.

The largest library in the Australian colonies is the Public Library of Victoria at Melbourne, which was established in 1853. In 1881 it numbered 39,887 volumes with 22,257 pamphlets; it possesses a collection of works on Australasia. The library has a printed catalogue (1880). It is supported by an annual parliamentary vote, which amounted last year to £5495. Readers are admitted without any formality, and have free access to the shelves. Although books are not lent out of the library individually, there is a system by which parcels of from 100 to 400 books are lent to libraries, mechanics' institutes, &c., in the inland towns of Victoria. There are several other not inconsiderable libraries in Melbourne. Next in importance to the Melbourne Library is the Sydney Free Public Library, which is said to contain the largest collection of works on Australasia anywhere to be found. It has a lending as well as a reference department, and is much used.

Particulars of other colonial libraries will be found in the tables.

United States.

The libraries of the United States, as we should expect to find in a country where intelligence and education are so widely diffused, are exceedingly numerous. A great mass of information with regard to them has been published by the Bureau of Education, particularly in

the comprehensive *Special Report on Public Libraries* issued in 1876. From this report, and the annual reports of the commissioners of education which have since appeared, we learn that the number of public libraries already registered is 3813, with upwards of 12,569,450 volumes. It is of course true that the great majority of these libraries are not numerically important. On the other hand, many of them are very rapidly growing, and their very youth implies that their shelves are not burdened with much obsolete literature. The recent development of American libraries is indeed very striking. Of the libraries reported in 1875, about 64 appear to have been established before 1800, and 30 of these between 1775 and 1800. Between 1800 and 1825 there were established 179 libraries, between 1825 and 1850 as many as 351, and finally between 1850 and 1875 no less than 2340, which in the latter year contained as many as 5,481,068 volumes. It will be convenient to deal with these libraries in groups according to the historical order of their development. The earliest libraries formed were in connexion with educational institutions, and the oldest is that of Harvard (1638). It was destroyed by fire in 1764, but active steps were at once taken for its restoration. From that time to the present, private donations have been the great resource of the library. In 1840 the collection was removed to Gore Hall, which was erected for the purpose with a noble bequest from Christopher Gore, formerly governor of Massachusetts. There are also nine special libraries connected with the different departments of the university. The total number of volumes in all these collections is 259,000, exclusive of over 200,000 pamphlets. The annual increase is about 7000 volumes, and the library has an endowment fund of over \$200,000. There is a MS. card-catalogue in two parts, by authors and subjects, which is accessible to the readers. The only condition of admission to use the books in Gore Hall is respectability; but only members of the university and privileged persons may borrow books. The library of Yale.

Yale College, New Haven, was founded in 1700, but grew so slowly that, even with the 1000 volumes received from Bishop Berkeley in 1733, it had only increased to 4000 volumes in 1766, and some of these were lost in the revolutionary war. During the present century the collection has grown more speedily, and now the main library numbers 102,000 volumes, while the special libraries in the control of the college bring up the total to 143,000 volumes. The yearly increase is about 4500 volumes, and the library has a book fund of \$100,000. Amongst the other important university libraries are those of the college of New Jersey (Princeton), Dartmouth College (Hanover), Amherst College, Cornell University, and Brown University (Providence, R. I.). In 1875 the number of college libraries (not reckoning academy and school libraries) was 312, besides 393 libraries belonging to college students' societies.

The establishment of proprietary or subscription libraries begins back into the first half of the 18th century, and is very connected with the name of Benjamin Franklin. It was at Philadelphia, in the year 1731, that he set on foot what he calls "his first project of a public nature, that for a subscription library. . . . This institution soon manifested its ability, was imitated by other towns and in other provinces." The Library Company of Philadelphia was soon regularly incorporated, and gradually drew to itself other collections of books, including the Loganian Library, which was tested in the company by the State legislature in 1792 in trust for public use. Hence the collection combines the character of a public and of a proprietary library, being freely open for reference purposes, while the books circulate only among the subscribing members. It numbers at present 123,000 volumes of which 11,000 belong to the

Loganian Library, and may be freely lent. The printed catalogues of the library has been praised by Brunet and Albion. In 1859 Dr James Rush left a bequest of over one million dollars for the purpose of erecting a building to be called the Ridgway branch of the library. The building is very handsome, and has been very highly spoken of as a library structure. Philadelphia has another large proprietary library—that of the Mercantile Library Company, which was established in 1821. It possesses 143,135 volumes, and its members have always enjoyed direct access to the shelves. The library of the Boston Athenæum was established in 1807, and numbers 122,000 volumes. It has recently published an admirable dictionary-catalogue. The collection is especially rich in art and in history, and possesses a part of the library of Washington. The Mercantile Library Association of New York, which was founded in 1810, has the largest of all the subscription libraries, counting over 193,000 volumes. New York possesses two other large proprietary libraries, one of which claims to have been formed as early as 1700 as the "public" library of New York. It was organized as the New York Society Library in 1754, and has been especially the library of the old Knickerbocker families and their descendants, its contents bearing witness to its history. It contains about 80,000 volumes. The Apprentices' Library has about 63,000 volumes, and makes a special feature of works on trades and useful arts. It is maintained by the General Society of Mechanics and Tradesmen. Finally, the Brooklyn Library deserves mention, if only for its very useful and admirable catalogue, the printing of which was completed in December 1880, and which embraces 60,000 volumes.

Although the State Libraries of Pennsylvania and New Hampshire are known to have been established as early as 1777, it was not until some time after the revolution that any general tendency was shown to form official libraries in connexion with the State system. It is especially within the last thirty years that the number of these libraries has so increased that now every State and Territory possesses a collection of books and documents for official and public purposes. These collections depend for their increase upon annual appropriations by the several States, and upon a systematic exchange of the official publications of the general Government and of the several States and Territories. The largest is that of the State of New York at Albany, which contains 116,000 volumes, and is composed of a general and a law library, of which a printed catalogue has been published with full subject-indexes. The State libraries are libraries of reference, and only members of the official classes are allowed to borrow books, although any well-behaved person is admitted to read in the libraries.

In addition to the libraries maintained by the several States, there are the collections belonging to the general Government, most of which are at Washington. The most important of them is of course the Library of Congress, but there are also considerable libraries attached to the houses of representatives, the senate, the department of state, the patent office, and the office of the surgeon-general.

The Library of Congress was first established in 1800 at Washington, and was burned together with the Capitol by the British army in 1814. President Jefferson's books were purchased to form the foundation of a new library, which continued to increase slowly until 1861, when all but 20,000 volumes were destroyed by fire. From this time the collection has grown rapidly, and now consists of 396,000 volumes with 130,000 pamphlets. In 1866 the library of the Smithsonian Institution, consisting of 40,000 volumes, chiefly in natural science, was transferred to the library of congress. The library is specially well provided in history, jurisprudence, the political sciences, and

Americana. Since 1832 the law collections have been constituted into a special department. This is the national library. In 1870 the registry of copyright was transferred to it under the charge of the librarian of congress. As two copies of every publication which claims copyright are required to be deposited in the library, the receipts under this head are nearly 25,000 articles per annum. The sum annually appropriated by congress for the management and increase of the library is \$52,840. The present accommodation is inadequate, and a separate building is to be erected of size to contain two million volumes. There is an alphabetical card-catalogue kept constantly up to date, and a printed catalogue of subject-matters. The library is open every day in the year, except on four legal holidays, from 9 A.M. to 4 P.M., and admission is granted to all persons over sixteen years of age without formality or introduction, but books are only lent to members of the official classes.

Since the organization of the Government in 1789, no less than one hundred and sixty historical societies have been formed in the United States, most of which still continue to exist. Many of them have formed considerable libraries, and possess extensive and valuable manuscript collections. The oldest of them is the Massachusetts Historical Society, which dates from 1781.

The earliest of the scientific societies owes its origin to Franklin, and dates from 1743. The most extensive collection is that of the Academy of Natural Sciences of Philadelphia, which consists of 36,000 volumes and 40,000 pamphlets. For information as to the numerous professional libraries of the United States—(theological, legal, and medical—the reader may be referred to the report already mentioned.

Of all the libraries of the United States none have achieved a Town greater fame, and none are more zealously and skilfully conducted, libraries than those which are supported from the public funds of some of the great cities. Legislation on the subject of free public libraries was almost synchronous in England and America. Of the free town libraries of America, much the largest and most successful is the Boston Public Library, which was established in 1822. Besides the liberal appropriations made by the city for its support, it has been the object of a long series of splendid gifts in money and books. Among the more conspicuous of its benefactors have been Joshua Bates, Theodore Parker, and George Ticknor. Since the library has been opened to the public there has thus been gathered "the largest collection of books, under one administration, upon this continent." The number of volumes in the library on July 1, 1881, was 305,478, and the annual accessions are over 17,000 volumes. In addition to the income available from trust funds, the annual appropriation by the city is \$116,000. Besides the central library, with the Bates Hall and Lower Hall, there are eight branches, and the total circulation is considerably over 1,000,000 volumes per annum. Any inhabitant of Boston over fourteen years of age is admitted to read in the library and to borrow books. The principal catalogues of the library is upon cards, in addition to which there are printed catalogues of special collections, and a perfect multitude of useful class catalogues and bibliographical helps of various kinds. The number of persons engaged in the service of the library is one hundred and forty-three. The library is open to readers from 9 A.M. to 6 P.M. from October to March, and until 7 P.M. during the rest of the year. Books are delivered for home use until 6 in the evening. The periodical room is open from 9 A.M. to 9 P.M. on week days, and on Sundays from 3 to 9. A new building is in contemplation.

Of the remaining free town libraries, the most important are those of Cincinnati and Chicago. The public library of Cincinnati, which was established on its present footing in 1837, has 122,000 volumes besides pamphlets. Its expenditure last year was \$21,465, and its total issues, including those from the two branches, were 768,566. The reading-rooms are open every day in the year from 8 A.M. to 10 P.M. The library buildings were completed in 1873 at a cost of about \$400,000, and are "among the handsomest in the world."

The Chicago Public Library was established in 1837, and owed its origin to the sympathy felt for Chicago in England after the great fire of 1871. The number of volumes now in the library is 76,120. There is a very full and minute card-catalogue, in one alphabet, of authors and subjects; the contents of collections, volumes of essays, &c., are analysed under their subjects. The reading-room is open three hundred and sixty-five days in the year from 9 A.M. to 9 P.M., and is not even closed for the purpose of taking stock or cleaning. The library has not yet an appropriate building. Of smaller free town libraries there is a considerable number, especially in Massachusetts. Of the entire number ten only supply over 50,000 volumes each. It is the opinion of the city engineer and

enlightened managers of these libraries that a free public library is the proper corollary of a free system of public education, and it is their aim as far as possible to direct the taste and to methodize the reading of those who use the collections under their charge.

Acator
library

We cannot conclude this brief sketch without mentioning some notable illustrations of that public-spirited sentiment which is nowhere perhaps so frequently found as in the United States. The Astor Library in New York was founded by a bequest of John Jacob Astor, whose example was followed successively by his son and grandson. The library was opened to the public in 1854, and at the end of 1889 the collection due to their joint benefactions contained 192,547 volumes. It consists of a careful selection of the most valuable books upon all subjects. It is a library of reference, for which purpose it is freely open, and books are not lent out. It is "a working library for studious persons," and such persons on a proper introduction are allowed to pursue their studies in the alcoves. In 1880 the number of general readers was 45,970, and the number of visits to the alcoves was 7901. The total endowment is over \$1,100,000. There is a printed catalogue for about half the library, with a printed index of subjects, and a similar catalogue for the rest is in preparation. The Lenox Library was established by Mr. James Lenox in 1870, when a lady of the name was incorporated by an Act of the legislature. In addition to the funds intended for the library building and endowment, amounting to \$1,247,000, the private collection of books which Mr. Lenox has long been accumulating is extremely valuable. Though it does not rank high in point of mere numbers, it is exceedingly rich in early books on America, in Bibles, in Shakespeare, and in Elizabethan poetry. The Peabody Institute at Baltimore was established by Mr. George Peabody in 1857, and contains a reference library open to all comers, numbering about 72,000 volumes. The institute has an endowment of \$1,500,000, which, however, has to support, besides the library, a conservatory of music, an art gallery, and courses of popular lectures. The largest legacy yet made for a public library has recently fallen to the citizens of Chicago. The Newberry bequest of over \$3,000,000 for the founding of a free public library in the north division of Chicago.

Lenox

South American and Mexico

Argen-
tine
Republic

The importance of public libraries has been fully recognized by the Argentine, and at present more than two hundred of them are in the country. They are due to benefactions, but the Government is every year adding an equal sum to any endowment. A central commission exists for the purpose of facilitating the acquisition of books and to promote a uniform excellence of administration. The most considerable is the Biblioteca Nacional at Buenos-Ayres, which contains at present 40,000 volumes, and has been almost doubled since 1872. It is especially rich in MSS., some of great interest, concerning the subjects of the Spanish colonies.

Brazil.

The chief library of Brazil is the Biblioteca Publica Nacional at Rio de Janeiro, founded in 1807, and now comprising 120,000 printed volumes with 1000 MSS. National literature and works connected with South America are special features of this collection. The Royal Library of Ajuda (founded 1600 MSS.) was taken to Brazil by King João VI, but was sent to Portugal on the declaration of independence. Since 1873 the annual Government grant has been largely increased. Among other libraries of the capital may be mentioned those of the Faculty of Medicine (18,000 volumes), Marine Library (19,600 volumes), National Museum (9000 volumes), Portuguese Library (63,000 volumes), Biblioteca Fluminense (48,000 volumes), Benedictine Monastery (9000 volumes), and the Biblioteca Municipal (16,500 volumes). In the official report on Brazil, submitted at the Philadelphia Exhibition in 1876, it was stated that the aggregate number of volumes in all the libraries of the empire accessible to the public was then 480,272 volumes. In 1875 the libraries were visited by 86,044 persons.

Chili.

Mexico.

The Biblioteca Nacional at Santiago is the chief library in Chili. The catalogue is printed, and is kept up by annual supplements.

Only sixteen out of the twenty-nine states and territories of the Mexican republic have public libraries, and only a small proportion of the contents consist of modern literature. Many, however, possess rare and valuable books, of interest to the bibliographer and historian, which have come from the libraries of the suppressed religious bodies. It is calculated that books in all the public libraries amount to about 250,000 volumes. There are about seventy-three scientific and literary associations in the republic, each possessing books. The Society of Geography and Statistics, founded in 1851, is the most important of them, and owns a fine museum and excellent library. After the triumph of the Liberal party the cathedral, university, and conventual libraries of the city of Mexico came into the possession of the Government, and steps were taken to form them into one national collection. No definite system was organized, however, until 1887, when the church of San Augustin was taken and fitted up for the purpose. Two copies of every book printed in Mexico must be presented to this library. The only other public library in the city is the Biblioteca Cisneros de Mayo, which is under the management of the Lancasterian Society.

The Biblioteca Nacional at Lima was founded by a decree of the Peru. The liberator San Martin on August 28, 1821, and placed in the house of the old convent of San Pedro. The nucleus of the library consisted of those of the university of San Marcos and of several monasteries, and a large present of books was also made by San Martin. The library is chiefly interesting from containing no more MSS. and rare books relating to the history of Peru in viceroyal times. The volumes marked "Papeles varios" contain reports on the superstitions of the Indians, abstracts of the ecclesiastical councils of Lima, and memoirs on provincial administration and petitions. It is reported (1881) that the whole library has been seized by the Chulinos and transferred to Santiago.

LIBRARY MANAGEMENT

Library Buildings.—The conditions of no two libraries being Buildings precisely alike, it is impossible to lay down rules to suit all, but certain principles of general application may be stated. In the first place the internal arrangements ought to be devised by a person thoroughly acquainted with the practical working of such a library as the building is intended to accommodate. The reading-rooms, book-rooms, work-rooms, and offices should be made to fall into the most convenient relations one to the other. And as libraries grow with wonderful rapidity the plan ought to admit of easy development. The site should be dry and airy, and permeable to the air of the town, which should be constructed of fire-proof materials, iron being preferable to stone, and brick to either. Every floor should be laid upon rolled iron beams, supported by lattice girders, the space between the beams being fitted in with porous terra cotta, and the beams covered with concrete. To protect them against fire, girders and pillars must be covered with terra cotta. Iron doors, or better still, stout wooden doors plated with thin iron) should separate the different rooms. The safety and convenient disposal of the books must never be sacrificed to outside show. The old form of library, the museum like room with alcove and a large block of recent space in the centre, or the series of apartments with bookshelves on the walls only, is no longer in favour. The reading-room, commodious, well lighted, and supplied with works of reference, should be away from the main collection, and the lending department should be kept apart from the reference library. It is convenient to have separate rooms for indices and for readers to whom special facilities may be granted, and for the provision of newspapers, and a reading room, office, catalogue room, and a library if necessary. The chief portion of the books (at any rate those in most demand) should be on the ground floor, and more than two stories are to be avoided. Plenty of light and good ventilation are two conditions of great importance. The basement should be raised above the ground level, or that in which the main collection is deposited, is one to which readers have seldom the right of access, the greatest economy as to drainage and passage may be effected. Bookcases may be placed against the walls, but not too close to them, and double presses, about 8 feet apart, arranged across the floor. To prevent the objectionable use of high ladders, no shelf should stand more than 8 feet above the ground. If the room be sufficiently lofty it may contain one or more perforated iron floors, sustained by the upright portion of the presses, also of iron. Spiral staircases are to be avoided. Lifts may be introduced with advantage. In many college libraries in America (e.g. at Princeton) the circular form, with access radiating from the centre, has been adopted successfully. The spacious rotundas of the British Museum and that of the Liverpool Free Public Library are good examples of the circular reading-room.

Mr. Justin Winsor has devised an excellent plan for a library of one million volumes capacity (see "Library Buildings," in *Report on Public Libraries of U.S.*, p. 446), and the same system might be applied to one much less extensive. Another distinguished American librarian, Mr. W. E. Froole of Chicago, has made some novel suggestions on library architecture which have met with considerable approval. He objects to the vastness of the circular plan, and to the large library rooms, to the difficulty of ventilating and heating them, to shuffling books in galleries on the walls, to the destruction of bindings from gas and heat ("books cannot live where man cannot live"), to the excessive labour of procuring books from long distances, the insecurity from fire, the inconvenience of keeping many volumes (other than those of reference) in the public reading-room, and the unnecessary cost of the present system. To remedy these defects a plot of land is required 200 feet square, and surrounded with open spaces. At the middle of the principal side may be placed the main building, 60 feet front and 15 feet deep, devoted to administrative and working purposes. The books will be stored, not in one central reading-room, but in a series of rooms thrown out in wings from the central edifice, and

¹ Plans of most of the chief libraries in Europe may be seen in the *Bibliothèques de France* of Mr. Edwards (7 vols., 1859), and in the *Kataloge der Bibliotheken der Preussischen Staaten* (1871); the volumes of the *Library Journal* contain representations of many new American libraries.

² A recipe to make wood incombustible, and other suggestions, are given by C. Welford in *Manchester Times Libr. Assoc.*, 1886, p. 65.

extending round the four sides of the quadrangle with a vacant space in the middle. Each room is 60 feet wide, 15 feet high, and as long as convenient. Ten of these rooms will occupy the ground floor, so that, carrying the same construction four stories high, there will be forty different rooms in the whole structure. Each will be devoted to one large, or two or more small, classes of books. Aisles and galleries are not to be permitted, but the books will be shelved on the walls or on double passages within reach. Every room will receive light on two sides, will be furnished with tables and chairs for readers, and provided with an attendant; no general reading-room will therefore be wanted. As a protection against fire, the roof will be cut off by means of brick fire-walls extending to the roof, and access from one room to the other will be by a light iron corridor on the inside of the quadrangle. At the rear of the central building will be a lift for readers, and there will be staircases as well. In this way, on one story there will be about 26,250 square feet in the different wings, which, after deducting sufficient space for readers' tables, &c., will give about 20,200 square feet for books. As each square foot will shelve 25 volumes, each story will hold 505,000 volumes, or on the four stories 2,020,000 volumes. One of the front rooms (to hold 67,500 volumes) might serve as a circulating library. Mr. Peole estimates the cost of such a library in America at \$530,000, or complete with shelving and furniture \$840,000. (See *Library Journal*, vi. 59.) In the same volume, p. 77 et seq., is a description of the proposed plan for a new national library building at Washington. In this scheme the architect has in view the centralization towards a circular reading-room, good light, the possible expansion of the library for one hundred years, accessibility to all parts, economical administration, and division into different fire-proof compartments.

Heating. Of the various systems for heating libraries open fire-places have the best appearance, are very safe, and best convey heat; close stoves are the cheapest at first hand. Perhaps steam heating is the safest and most economical for large buildings. Unprotected gas jets are very injurious to the books. If gas be used at all, the open-light system or the Denham light is the best means of conveying away the fumes and heated air. The electric light is used with great success at Liverpool and the Museum of Natural History.

Shelves. *Bookcases and Shelves, Furniture and Appliances.*—For presses and shelves, should wood be preferred, English oak or the cheaper deal (well seasoned) as the best material; or the presses may be made of iron and the shelves of slate or galvanized iron. At the British Museum the presses are all of one size and of the same model—the standards being of galvanized iron, with holes for brass pins, which are so shaped that the space is altered by merely turning them half-way round. The shelves are also of galvanized iron, covered with leather, on wooden frames; movable pads covered with leather at the ends of the books at either end being rubbed, and there are leather falls to keep the dust out. In the Radcliffe room bookcase, invented by Dr. Adams, the framework is of iron, and the shelves of wood, faced with leather. It is 7 feet high, and stands on any floor-space 48 inches by 18 inches; books are placed on both sides to the number of 600 volumes. Danner's revolving bookcase is useful for reference books; it is square, stands about 5 feet high, occupies no more space than a chair, and holds about 950 volumes. Economy of space is also a feature in Mr. Virgo's bookcase, the front of which is a door, itself shelved, which, on being swung round, discloses another row of shelves behind. The Radcliffe portable bookcase is taken to pieces, and is made to stand against a wall. In providing for shelf room it is usual to allow about 110 square feet of shelving to 1000 volumes; and in giving directions for presses and shelves it is well to have them planned upon a uniform scale. Perhaps the best supports for the shelves are Tuck's movable book-rests, consisting of two rows of metal strips, with oblong perforations at intervals of 2 inch, in which are inserted small metal plates. The tops of reading tables, trays and barrows for carrying books, and such shelves as may be intended for heavy or choice books, should be padded. Very large volumes had better be kept flat in sliding trays. There is much diversity of opinion as to whether the fronts of the presses should be glassed or not, or whether they should be protected by wooden doors, curtains, or wire screens; many libraries object to glass doors as harbouring dirt, and to any opaque screen as concealing the books.

**teading-
room.** The arrangements of the reading-room of the British Museum furnishes a good example of perfect execution combined with every consideration for the comfort of readers. The tables are arranged as the spokes of a wheel, with smaller square tables between them for large volumes. Each reader at the radiating tables has a separate place 4 feet 3 inches long, and is screened from his opposite neighbour by a division running along from one end to the other; in front is a hinged desk, with racks, inkstand, and a folding shelf for books. The framework of each table is of iron, forming channels by which air is conveyed through screens at the top of the longitudinal divisions. A tubular foot-rest affords facility for warming the feet in cold weather. The catalogue-shelves (which

presses of special bibliographies near them) are placed in two concentric circles around the enclosure of the superintendent, who can thus observe every reader in the room.

A speedy supply of books is ensured by the use of the automatic Supply-book-delivery contrived for the Harvard bookstore (of six stores) by Mr. Justin Winsor. At the delivery-desk a key-board shows the digits which combine the various shelf-marks; and the number of the book wanted, being struck upon it, is repeated at the floor on which the work is located, where it is sought for by an attendant and placed in a box attached to an endless belt, which carefully deposits it on a cushioned receptacle close by the delivery-desk.

Many English lending libraries find that a great saving of time and trouble both to officials and readers is made by the use of the indicator for public reference. There are many varieties of this invention, but the main principle is a frame containing a series of small pigeon-holes, each numbered and referring by fixed number to a book, when a volume is lent out, the borrower's card, &c., is placed in the pigeon-hole and signify that it is absent. This roughly describes the Birmingham indicator (Mr. Morgan's) in that of Mr. Elliot, the title of the book is pasted against each pigeon-hole, Mr. W. H. K. Wright uses at Plymouth a system which serves as a catalogue and register of books lent as well, and Mr. J. C. Cotgrave has improved the original idea by his indicator-board, a sort of ledger of the persons to whom each volume is lent, which is placed in the small pigeon-hole previously spoken of. The card-keeper of Mr. G. Parr, used at the London Institution, is for the use of the librarians close and not for the readers, it is applied to a borrowing system which permits several volumes to be taken away by the same person, and also acts as a register of borrowers.

For the purpose of stamping the name of the library on the books, Minor &c., some persons prefer the embossing stamp, and some the ink-planes stamp now very conveniently made in india-rubber. Props, either to screw upon the shelves, or made of thick blocks of wood, or of its folded at right angles, are useful for preventing books falling about in a slovenly manner. Reading cases are necessary for periodicals and choice bound volumes; periodical cases are made conveniently of wood with strong leather backs. In order to keep the consecutive numbers of current periodicals and newspapers clean and in good order, some kind of temporary holder is required. The contents of the different shelves or presses may be printed on labels made of leather or cloth. The "Van Everen" printed numbers and letters for the marks on the shelves and the backs of the books are to be purchased at a small cost.

Classification and Shelf-Arrangement.—The defect of most classification systems, especially of those which profess to be particularly turn, philosophical and logical, is that they are better adapted for a systematic review of human knowledge than for the arrangement of a miscellaneous collection of books. A small library will not require so extensive a scheme as a larger one, and a popular library needs less minute classification than one for reference or for the use of more learned readers. Again, the classes which are best represented in the library, and its special or local collections, deserve more elaborate treatment than the classes in which it possesses but few volumes. The same system cannot invariably be used in all respects both for its shelves and for the catalogue, as a book can have but one position in the presses, but the title may appear under many numbers of headings in different parts of the catalogue. For these reasons, the natural order should be followed as far as possible. That is to say, the books should suggest their own classification, which should be made to harmonize with the requirements of the library, and the various classes should not be strained to fit some arbitrary method, however logical in theory. As the title of a book is often an unsafe guide to its contents, no one should attempt classification by the title alone. The *Index Librorum*, vol. i. *Index Librorum*, &c. gives a number of schemes both on philosophical and on natural or practical principles; and Petzhold, in his *Bibliotheca Bibliographica* (Leipzig, 1805), has drawn up an account of no less than one hundred and seventeen different methods of classification, a number which could now be largely increased, as the practical necessity of American libraries alone has added many to the roll. Some of these schemes have been elaborated with great care, but, however interesting on account of the useful hints they may now and then supply, most of them are useless either for the catalogue or the shelves. All these are systems to classify the whole range of literature, but there are many classified catalogues, and many other guides useful for the scientific arrangement of special departments.⁴

Books are usually arranged upon the shelves either in order of (1) their sizes, (2) authors' names, (3) subjects, or sometimes (4) of accession, or by a modification of two or more of these systems. The arrangement by subjects is that which displays

⁴ See the *Oxford Treat. Lib. Assoc.*, 1876, p. 70; *Manchester Treat.*, 1880, p. 12.

⁵ For instance, in the class of fine arts may be comprised the *Bibliothèque des Beaux-Arts* (Paris, 1874-75), which the *Index Librorum* lists in complete; and *Library may be classified with the help of Dr. J. C. Cotgrave's* *Index Librorum* (London, 1881). In the *Memoria Librorum* (1921) may be found a useful classification for MSS. and further on an account of printed MSS. and systems for printed copies, being those of the *Bibliothèque* and the *Index Librorum*.

dressing may be found necessary. The volumes must be rubbed with chamois leather when dry. Nail-foot or olive oil has been suggested for the same purpose, but it ought to be used with a sparing hand. Much has been written about the effect of gas and heat upon binding. The question is still undecided, but it seems likely that the deterioration of the leather is caused more directly by the over-heated air, so that thorough ventilation, especially as regards the upper shelves, is most important for the well-being of a library. Morocco, vellum, and buckram resist this action best, and calf, russet, and roan worst. Professor H. A. Hagen has studied the various kinds of bookworms and other insect pests of libraries.¹ Most libraries of the first class find on the premises, and M. Hippé Ganel of the Bibliothèque de Grenoble is persuaded, after a very careful inquiry, that any library which finds as many as nine hundred volumes a year will save largely by keeping up a binding establishment of its own.²

his-
tories

Catalogues and Cataloguing.—A library is useless without a proper equipment of good catalogues, which to be thoroughly efficient should be compiled upon a well-considered plan, carefully kept up to date, and made accessible to every reader. The variety of different catalogues is very great, and no one form can be adopted alike by libraries for study and those for popular reading, nor yet by those which combine the two functions in whatever proportion. It regards the amount of information necessary to be given, the titles of the books may be either short, or not more than a single line to each, as in the *London Library Catalogue* (1875), medium, or several lines to each, as in the *Royal Academy Library Catalogue* (1877); or full, as in the *Catalogue of the Hertz Library*, 5 vols. large 8vo (1880), where the title is copied in extenso and a quantity of bibliographical details are added.

The chief questions to be answered by a catalogue are—1. Has the library a certain work by a certain author? 2. What has it by any given author? 3. Has it a certain book of which the title only is known to the inquirer? 4. Has it a certain book of which the subject only is known to the inquirer? 5. What has it on a given subject? 6. What works in certain classes or languages has it? To supply this information, catalogues are arranged sometimes under the names of the authors in alphabetical order (1 and 2), or under the first words of the titles, or classified under subjects, whether in alphabetical or systematic order (4 and 5), or by a combination of two or more of these methods. A dictionary-catalogue answers all six questions under the names of authors, the titles of books, the subjects and forms of literature (i.e., essays, or French, German, or Latin, or in one alphabet). A subject-catalogue is connected one with the other by a complete system of cross-references. A modified form of short-title dictionary-catalogue, with the names of authors, titles of books, and subjects in one alphabet, is a useful type for a popular library to adopt. No author-catalogue can be considered complete without an index of subjects,³ and every classified catalogue requires an index of authors, if alphabetical, and of both authors and classes if systematic. An ideal catalogue would furnish references under each name and subject to every work, part of work, or even magazine article contained in the library which illustrated it. This can rarely be attempted, but a near approach to perfection is shown by the new catalogues of the Boston Athenæum and the Brooklyn Mercantile Library; the last is a model of thoroughness. It is becoming a laudable practice to give the contents of collected works and periodicals in catalogues; and good examples of the value of annotations are the catalogues of the classes of history, biography, travel, and historical fiction in the Boston Public Library.

In making choices of a form of catalogue the way is sufficiently plain should the alphabetical system under authors be adopted, neither can there be much cause for discussion in fixing upon an alphabetical subject-catalogue, but should it be decided to compile a systematic subject-catalogue, the question becomes a much more serious one. A subject-index of some sort is an indispensable supplement to any catalogue merely arranged under authors. The reference list better be strictly alphabetical in form; for instance, a work on ants should be indexed under that word and not under the general heading of insects or entomology; but there is no reason why there should not be cross references under the latter to the smaller headings. In an appendix to Mr. Cutter's article on "Library Catalogues,"⁴ there is a descriptive list of more than a thousand printed catalogues of American libraries, among which many useful types might be selected. All the printed catalogues of European libraries which were published before 1860 are mentioned in Vogel's *Literatur-corp. off. Corporations-Bibliothek* (Leipzig, 1860).

Librarians should take a share in the compilation of their catalogues at any sacrifice of time and trouble, for by no other means can they obtain so exact an acquaintance with their collections. No

cataloguer should be allowed to prepare a title except from the very copy of the book which he is cataloguing.

In order to secure precision and uniformity in the descriptions of the books and in the headings under which they are placed, some well-considered code of rules is absolutely necessary as a guide to the cataloguer. All such rules are founded upon the regulations of the British Museum, printed in 1841,⁵ which have been followed with modifications by Professor Jewett (in the *Southwestern Report on the Construction of Catalogues*, 1853), by Mr. E. Edwards (*Memoirs of Lais*, 1859, vol. ii.), by Mr. F. B. Perkins (in the *American Publisher*, 1869), with many additions by Mr. C. A. Cutter (in his *Rules for a Practical Dictionary-Catalogue*, 1876),⁶ by the condensed rules of the American Library Association (*Library Journal*, vol. 13), and by the Library Association of the United Kingdom (as finally agreed upon and printed in their *Monthly Notes*, no. 51). The authorities of the Cambridge University Library have also printed their rules in drawing up a set of rules the special wants of the library and the readers should be first considered, and then the most suitable rules chosen from one or other of the schemes mentioned above. But when rules are decided upon, no alteration should be permitted during the compilation of the catalogue, as bad rules uniformly followed are better than good rules without uniformity.

Among disputed questions, that of how best to describe the sizes of books is perhaps the most difficult. What is wanted is a system that can be understood by every one, and which is capable of being applied to old as well as to new books.⁷ For books printed before the introduction of machine-made paper about the beginning of the century, the correct bibliographical size may be derived from the fold of the sheet, that is, roughly speaking, a quarto is a sheet folded four times, an octavo eight times, &c. The great variety of modern papers (a different sort of sizes being used in each country) renders this method no longer available, and it seems generally admitted that some system of fixed measurements of heights to denote certain sizes is wanted for library purposes. A report on the subject, giving details of three rival schemes, including that of the American Library Association, an ingenious adaptation of the "demy" scale paper, and one following the ordinary binder's scale, may be found in *Trans. &c., of Manchester Meeting*, 1880 (p. 11). The Library Association, a committee of which was subsequently deputed a plan which endeavoured to embrace the different merits of all three schemes, but it has not yet been generally adopted.⁸

Printed catalogues are doubtless costly, and they soon become out of print or a higher price is demanded to consult them; manuscript catalogues, and possess the great advantage that they admit of being enlarged or altered away from the library. On the whole the balance of convenience is strongly in their favour, and few libraries of any importance fail to print as soon as they can. For free public libraries printed catalogues are absolutely necessary, and they are extremely useful in those a more learned or special character.

As regards the form of catalogue most suitable for library reference, card-catalogues are used comparatively little in England, but are found to not satisfactorily in many American libraries. They possess many peculiar advantages, among others being the facility with which they may be added, withdrawn, or rearranged. Readers do not object to turning over the cards as the labour is shortened by indexes standing above the rows, and there are many contrivances to prevent the unauthorized removal of the title.⁹

It is obvious that, if a universal catalogue of printed literature existed, it would be only necessary for each library to mark in a copy of this universal catalogue the particular works it possessed. Such a plan is small scale has been adopted in many cathedral and college libraries, where a copy of the Bodleian printed catalogue is used for the purpose. A satisfactory step in the direction of co-operative cataloguing has been made by Mr. Henry Stevens in his proposals for a "bibliographical clearing-house,"¹⁰ which shall supply exact copies of the title pages of rare (and eventually of more common) books by means of photography. Mr. Stevens has now many thousands of these "photographs" of titles, which are all reduced to a uniform scale, with the full titles and collations added in ordinary type. They are very convenient for card-catalogues.

Thus far the wants of readers have been principally considered; but librarians ought to possess two other kinds of very important catalogues, which they must keep up in their own interests. The first is the accession-catalogue, or record of every book, part of book, pamphlet, or periodical as it comes in; and the second the shelf-catalogue, or stock-book of the library, a register of the con-

¹ Prefixed to the printed catalogue of Mr. A. The rules, which were compiled by Mr. A. and printed by The West & Wither Journals, have been conveniently arranged by Mr. Nichols in *Handbook for Readers at the British Museum*, 1860, and have been reprinted with additional rules by Mr. Ry. Stevens in *Ms. Catalogues of the American Library at the British Museum*, 1860.

tracts of every press and every shelf. These tell the source and date of every addition, and enable all the books to be checked at any time. A novel form of accession-catalogue is that of the Liverpool Free Public Library, which is a sort of large photographic album to show printed titles of accessions in alphabetical order. Loose sheets are filed into the body of the catalogue to provide for any number of additions as quickly as possible. In the same library the titles of new books are also pasted upon blocks arranged in a frame for the information of readers.

Accounts.—Administration.—In any library which manages its own financial transaction, however small, all accounts should be as carefully kept as those of a trading establishment. In the same way a permanent steel-taking should be made by means of the self-catalogue. It is a great convenience to display recent accessions for a short time in some place just apart for the purpose. A recommendation and complaint-book are both useful. The loyal and efficient supply of books is greatly promoted by returning that all demands should be made in writing and not verbally. The books should be carefully dusted from time to time by experienced persons, and the leaves of all new books, &c., should be cut by the library staff.

In issuing and taking notes of books lent, either the ledger or the slip-system may be used, or a combination of the two, something like a self-catalogue. Accounts are kept either against the borrower, against the book, or against time; the first, with the ledger system, may be well for small libraries, but in larger institutions the slip-system must be resorted to, and it is better to keep the accounts against the books, with perhaps a ledger-index of borrowers. Where more than one volume is lent at a time a small card is sometimes placed in a pocket in each book; the card, whether marked with borrower's name, &c., or not, being retained as a voucher, as at the "card-ledge" spoken of on p. 137, which is on the slip-system with the account against the borrower. The special feature of the "card-ledge" is that no writing whatever is required. It is necessary to introduce some device for overdrawn or reserved books.

Besides furnishing the materials for reading, it is now recognised that a popular library has also the function of indicating the method of reading and study. A collection of well-chosen books suitable for adults and boys is one thing; and leading in many English free libraries. At the Providence Public Library, Rhode Island, Mr W. E. Foster issues daily notes on current topics and events, with detailed references by which the subject may be illustrated by the resources of the library; more complete special lists, e.g., on Helbig Spencer, Irish landless and towns, &c., are issued from time to time. Library lectures are now given at several free libraries in England, but, to make these efforts distinctly useful in adding to the good work of the institution, they should be restricted to lectures on books and courses of reading, so that, by illustrating certain works or departments of the library, these lectures may gradually lead readers to a more careful consideration of literature. Aimless and purposeless reading is the bane of a free public library, and it should be the desire of its authorities to do what can be done to induce people to use with due discrimination books of a higher class and of a more useful and informing character. The admirable catalogue of history, geography, and travel of the Boston Public Library, with its suggestive notes and illustrations, had the effect of lowering the reading of fiction from 74 per cent. to 69 per cent. In the same library even the reading of novels has been elevated by the catalogue of English prose fiction arranged on the same plan.

Experience shows that in all that relates to such questions as preliminary forms, age of readers, days and hours of admission, Sunday-opening, access to catalogue, shelves, and libraries, fine loans of books, guarantees, number of volumes allowed, time of reading, &c., a liberal tendency is always beneficial both to the library and the public.

Precautions against fire.—In view of the outbreak of fire, some well considered plan should be fixed upon. Extinctors and hand-pumps should be kept ready for use in central positions. The means for extinguishing fire should be familiar to the members of the staff, who should all be practised in fire-drill, in order that each may know his proper place and duty in case of emergency. Full directions should be suspended in conspicuous places. In the case of fire breaking out after library hours, it should be thoroughly understood where the keys are to be found, what officials should be sent for, and what apparatus is ready for use within the building.

Librarians.—Without insinuating upon quite so wide a range of subjects as did F. A. Herbert in his *History des Bibliothécaires* (London, 1820), one may expect the librarian of a great library to be a man of liberal education, and specially endowed with sympathy with books and reading, a practical acquaintance with bibliography, including palaeography, and bibliography, is also necessary, as well as with the theory and practice of library management. To be thoroughly qualified, a librarian should have had the practical experience of library-work which it is impossible to obtain from any amount of book-reading. Besides this, he ought to be a man of business habits and a good administrator.

These requirements imply qualifications of a somewhat higher

character than may perhaps be necessary in all public libraries; but some knowledge of languages and literatures, bibliography, bibliography, and general library management should be possessed by any person holding the chief position in the administration of any library, however small. As regards the qualifications of the librarian of a popular institution or of library-assistants, it may be useful to give the outline of a plan recently proposed by a committee of the Library Association for their examination (see *Monthly Notes*, vol. ii.). There should be a preliminary examination, chiefly in the subjects of a sound English education, special attention being paid to English literature, proficiency in the elements of one or more classical or modern languages would be specially indorsed upon the certificate, one language to be necessary. The suggested subjects for the preliminary examination are—athletics, English grammar and composition, English history, geography, and English literature. After having been engaged in library work for not less than one year, a second-class certificate might be awarded to any librarian or assistant who should pass a satisfactory examination in English literature, especially of the last hundred years, some one other European literature, principles of the classification of the sciences, elements of bibliography, including cataloguing and library management,—a cataloguing knowledge of at least two languages being essential, to be necessary. A first-class certificate would be given, after a satisfactory examination, to a librarian or assistant of at least two years' experience, for an advanced knowledge of the subjects last mentioned, with the addition of general literary history. A cataloguing knowledge of at least three languages would be necessary for the higher certificate,—an acquaintance with any other, as well as proficiency in any subjects (not more than two in number) offered by the candidate, being specially indorsed.

Women are gradually making their way in libraries. At Manchester and elsewhere they are successfully employed as assistants, and in several other places in England the chief charge of the library is maintained in a very efficient manner by a lady. In the United States the majority of the librarians are ladies (at the Boston Public Library no less than two-thirds of the staff), and many of the most accomplished cataloguers are of the same sex.

The first general meeting of librarians took place at New York, September 15 to 17, 1863, upon an invitation extended by Professor C. J. Jewett, Mr F. F. Poole, and others "for the purpose of conferring together upon the means of advancing the prosperity and usefulness of public libraries, and for the suggestion and discussion of topics of importance to book collectors and readers." About eighty persons attended, many questions were debated, and the suggestion was made, a permanent association met with considerable favour. Nothing came of it, however, and twenty-three years had elapsed when, having in view the Centennial Exhibition of 1876, a second meeting was convened on October 4 to 6, at Philadelphia, which was attended by one hundred and two Americans and one English representative.

At the Philadelphia conference of 1876, the American Library Association, which has since done so much good work in practical librarianship, was founded. In October 1877 a conference of librarians was held in London, under the presidency of the late Mr J. Winter Jones, and attended by two hundred and sixteen librarians and others, including representatives of the French, German, and Greek Governments, all the chief libraries of the United Kingdom, as well as certain of those of the United States, Belgium, Denmark, France, Italy, and Austria. Altogether one hundred and forty different libraries sent representatives, and nearly the whole field of library-science was reviewed at the different sittings. *The Transactions and Proceedings of the Conference of Librarians* (London, 1878) is the title of the official report of the meeting. The chief result of the conference was perhaps the foundation of the Library Association of the United Kingdom, of which the "main object shall be to unite all persons engaged or interested in library work for the purpose of promoting the best possible administration of libraries; it shall also aim at the encouragement of bibliographical research." Monthly meetings of the association take place at the London Institution, and the members hold an annual conference in some one or other locality, where the different libraries are inspected, various questions of library economy are discussed, and new library appliances are exhibited. Full reports of these meetings have been published. *Monthly Notes* are also issued. Every important British library is now represented in the association, which numbers over 350 members.

Guides to Selection of Books.—As it is not only necessary to find out Selection the best treatises on given subjects, but also to decide upon the respective numbers of different editions and even of different translations or copies of the same edition, an acquaintance with bibliography, or the science dealing with the technical features of books and MSS., and with bibliography, or that which deals more especially with their literary aspect, as to be expected in those forming a library.¹

¹ The article *BRITANNICA* (vol. iii. p. 631, pp.) will afford a general idea of the immense extent of this literature, in addition to the special works there mentioned. Reference may be made to Bain's *Bibliography of Bibliography*, New York 1877.

So necessary is bibliography in library selection that Dr Cogswell, as a preliminary step to collecting books for the Astor Library, formed a bibliographical apparatus of five thousand volumes to help him in his arduous task. To assist librarians and collectors in their choice, among earlier works may be mentioned that of G. Pagnet, *Manuel Bibliographique, ou guide des livres*, Dijon, 1828, still interesting on account of the descriptions of the favourite reading of eminent men. *Catalogue of my English Library* (London, 1863) is the title of a little volume prepared by Mr Henry Stevens to assist in getting together the best editions of the standard English authors. The idea was followed on a larger scale by M. Hector Bosangue, *Ma Bibliothèque Française* (Paris, 1866). The best guide for ordinary purposes, but far from perfect, is *The best Reading, hints on the selection of books, on the formation of libraries, public and private*, by F. B. Perkins (4th ed., New York, 1877). The list is restricted to books now in the market; prices are appended. The titles are very brief, and are arranged in an alphabet of subjects, and a selection is appended of the chief French, German, Italian, and Spanish authors. A new edition of Porter's *Books and Reading* appeared in 1881. Current German literature is well looked after in G. Schwab and K. Klüppel's *Wegweiser durch die Literatur der Deutschen* (4th ed., Leipzig, 1870), with several supplements. The leading literary reviews, as well as the publishers' trade journals, will guide in the acquisition of the books of the day. The careful cataloguing and excellent descriptive notes in the *New York Publishers' Weekly* are good examples of what book committees are glad to have before them. An examination of the authorities quoted by authors of repute will frequently help in deciding upon the merits of rival treatises, and the printed catalogues of well-chosen libraries are also useful. To his practical little treatise, *Five Libraries and Newsrooms*, Mr J. D. Mulline appends a list of books he considers desirable for five public libraries, and to form the basis of a collection of high-class fiction. Mr F. B. Perkins has drawn up a list of the best hundred novels procurable in English (*Library Journal*, 1, 166). *The Coming Catalogue*, about which we hear now and then from America, will contain selected lists of books, with short notes.

Acquisition

Acquisition of Books—Public libraries must look to purchases as their chief means of getting the books that want raising. The best system is to draw up lists of the desired works and editions, and circulate this lists among the leading booksellers, who will notify the prices and conditions of the copies they may be able to supply; announcements of books wanted can also be inserted in the booksellers' trade organs. Second-hand booksellers will willingly furnish their catalogues if they are not required to purchase them, are always useful for reference. It is usually more convenient to give commissions for books at sales than for the librarian to attend in person; but an occasional visit to the auction room will give much information as to current prices of books, a matter which, coupled with frequent visits to the shops of second-hand booksellers and the diligent study of their catalogues, will be carefully attended to by the capable librarian. The works of Brunet, Lowndes, and Gessner may also be consulted for the prices of old books. It is perhaps needless to add that the state of condition and binding makes a great difference in the market value of copies of the same book. Libraries will frequently despatch their duplicate or surplus copies to other institutions at a low price. For new books, periodicals, newspapers, &c., special terms may always be arranged with local tradesmen.

From time to time the Governments of Great Britain, France, and the United States have had under consideration various schemes for the international exchange of books upon a systematic basis, but the proposals were never carried into effect, and it was left to the public spirit of a French gentleman, M. Alexandre Vattemare, to devise and carry out for some years a large scheme for the interchange of books among the chief public institutions of Europe and America. In 1883 M. Vattemare was able to state that one hundred and thirty such establishments had participated in the benefits of the system, but unfortunately it gradually fell off. Earlier than 1861, however, a similar agency was in full working order at the Smithsonian Institution, and it has been kept up with efficiency to the present time. The institution acts as a medium for the exchange of their publications among the chief learned bodies and other public institutions of Europe and America, and undertakes the cost of receiving and sorting the parcels, and the remuneration of the agents in the chief countries of the Old World to whom they are sent; and by whom they are distributed free of charge. The corresponding societies are only required to deliver their parcels without expense at Washington.

On several occasions the United States Congress has passed special Acts directing the exchange of Government publications with those of other countries, and in 1848 the joint committee on the Library was authorized to appoint agents for the exchange of books and public documents. As the scheme did not appear to work satisfactorily, the Act was repealed four years later. But since 1867 it has been ordered that fifty copies of all documents printed by either House of Congress or by any Government department be placed

with the joint committee on the library, to be exchanged for foreign works. It is most unfortunate that this enlightened policy is not followed by the English authorities.

Many learned bodies which issue their proceedings willingly present them to libraries, and authors find this a useful means of spreading knowledge of their works, while they can secure for the public interest to ensure a large or rapid sale. Library committees may often secure valuable additions by a discreet application; indeed, privately printed works and local publications (unless given spontaneously) are almost only to be had in this manner.

Many valuable works are issued at the expense of Governments. It might be mutually expected that these should be sent, free of charge, to all public libraries of any importance. In England, however, this is not done. In countries where the public libraries are subject to the minister of public instruction, as in France and Italy, more is done in this direction, especially as regards expensive volumes. In 1858 a select committee of the House of Commons recommended that parliamentary papers should be sent free of charge to free public libraries, but the recommendation has never been carried out.

In America official publications can be obtained without charge by public institutions from the secretary of the interior upon the order of a senator or representative, but the system is said not to be a satisfactory condition.

Many valuable English Government publications, notably the state papers and chronicles, and the fine art handbooks of the South Kensington Museum, are easily to be had at less than the cost of production, and parliamentary papers are neither unobtainable nor highly priced. Although there is no fixed rule as to distribution, some of the departments may now and then be induced to present copies of their publications on being applied to in a proper manner.

The privilege of demanding copies of all books, periodicals, news, Copyrights, musical publications, maps, and prints, when published, right under the provisions of the various Copyright Acts, is enjoyed by Acts only a very few, generally only by one, of the chief national libraries in each country. This system has grown up under the different enactments of the ownership of the press. The first Act of Parliament passed in England to enrich printers to present their publications was that of 14 Charles II. c. 24, which provided that three copies should be sent, one to his Majesty's library, and one to each of the universities of Oxford and Cambridge. By 8 Queen Anne c. 20 the number was increased to nine, and by the 41 George III. c. 107 to eleven, viz., to (1) the Royal Library; (2) the University Library of Cambridge; (3) the Bodleian; (4) Edinburgh University Library; (5) Glasgow University Library; (6) King's College Library, Aberdeen; (7) University Library, St Andrews; (8) Queen's College Library, London; (9) Advocates' Library, Edinburgh; (10) Trinity College Library, Dublin; (11) King's College Library, Dublin. This was in force till 1835, when by 5 & 7 William IV. c. 110 the privilege was abolished as regards six of the eleven libraries mentioned, and a yearly grant, estimated at £8008, allowed in compensation. The Act under which five libraries, viz., the British Museum, the Bodleian, the Cambridge University, the Advocates', Edinburgh, and Trinity College, Dublin, now receive the copyright books is 5 & 6 Vict. c. 45 (See Copyright, vol. vi. p. 358).

As instances of the variety in practice in different countries, it may be mentioned that in France the Bibliothèque Nationale is entitled to a copy of every book, &c., printed within the dominion of the republic; in Belgium and the Netherlands one copy must be sent to the respective national libraries in order to secure the advantage of copyright; in Spain the Biblioteca Nacional of Madrid enjoys the privilege of one copy; in Portugal two copies are claimed, one by the Biblioteca Nacional at Lisbon, and one by the Biblioteca da Publica de Oporto; in the Cape of Good Hope every work must be sent to the library of Congress; the Imperial Library at St Petersburg receives two copies of every book printed in Russia; by the Brazilian law the Biblioteca Nacional do Rio de Janeiro is entitled to a copy of everything published within the municipality; and in Mexico two copies have to be delivered to the National Library.

Authorities—There have been many books written about library management; a complete list of those published down to about 1866, with critical notes, is given in *Fachschule Bibliothekswissenschaft*, by Dr J. G. Schneider. Besides the valuable works of Mr Edward Edwards, *Managers of Libraries* (1859, 3 vols. 8vo), *Five Seven Libraries* (1860), *Libraries and Founders of Libraries* (1868), *History of the Foundation of the British Museum* (1871, 3 vols. 8vo)—which are in the hands of all librarians. *Fachschule Bibliothekswissenschaft* (Leipzig, 1871) is a practical little volume. The report of the Bureau of Education on *Public Libraries of the U.S.* (Washington, 1874, 3 parts 8vo), besides giving an exhaustive account of all the American libraries, also includes a great variety of valuable information on library economy. The volume is so well illustrated, and contains so much that is useful for practical librarianship; it is a well edited periodical. *Fachschule Bibliothekswissenschaft* is a well edited periodical. The different publications of the Library Association include a great deal of interesting matter.

¹ In the recent *Report of the Royal Commission on Copyright*, 1875, a recommendation is made that the privilege should in future be granted to the British Museum alone.

(H. R. T.—H. G. T.)

LIBURNIANS were a people who at different times were prominent on the Adriatic coasts. They were originally, one cannot doubt, one of the homogeneous Illyrian tribes (see **ILLYRIA**). Living in a barren rocky country along the north-eastern coast of the Adriatic, they devoted themselves to the sea, and were the chief navigators of the Adriatic in the early period. They settled on the coast of Picenum, where the town of Truentum was always counted Liburnian, and the Greek colonists found them at Corcyra and other places. They were pressed on all sides by other races, but were still a powerful people in the time of Scylax (Scyl., p. 7). The islands that lay along the coast were peopled by them and called by their name. They were a race of pirates, who used swift boats with a large sail. These Liburnian ships became famous when the Romans adopted them in several of their naval wars. The heavy and lofty ships that had been developed by the later Greek states proved unequal to the light and swift Liburnian boats. The country was incorporated by the Romans in the province of Dalmatia.

LIBYA was a geographical name by which the Greeks usually designated Africa, with the exception of Egypt, although sometimes the continent was thought to be divided between Libya and Ethiopia. Libya enters into the sphere of ancient history only in so far as it came into contact with the civilized races of antiquity, and the present article will

touch this point only; the natural features and the ethnology will be found under other headings (see **AFRICA**). The native tribes came several times into collision with the kings of ancient Egypt. In the reign of Rameses the Great and his successor they invaded the Delta, and various expeditions were made by the Pharaohs into the outlying country, on the south particularly (see **EGYPT**). Herodotus mentions one important expedition sent out by Pharaoh Necho (610-594 a.c.), which started from the Red Sea, circumnavigated the continent, and reached the mouth of the Nile after three years' absence. The truth of the tale has often been doubted, but one circumstance in which Herodotus himself expresses his disbelief, viz. that as they sailed west they had the sun on their right hand, has in modern times been generally accepted as proving that the voyage was actually made.

The Phœnician colonies on the north coast, Utica, Carthage, &c., beginning between 1000 and 800 a.c., established a powerful and civilized empire in a hitherto unknown part of Libya. Their trading expeditions gave them a wide acquaintance with the geography of the country, even with the Atlantic coast as far almost as the equator; but the contempt with which the Roman conquerors treated the literature of the Carthaginians allowed much valuable material to disappear. The historian Sallust, when praetor of Numidia, was still able to use the Punic records which

he got interpreters to translate for him (Sall. *Jug.*, 17); and fortunately one record of an exploring voyage along the west coast, preserved in a temple in Carthage, was translated by some Greek traveller and is still available (see HANNO). For all that is known of the Carthaginian rule in Libya see CARTHAGE.

Greek mariners must have visited Libya at a very early period, for the edible lotus of the northern coast is mentioned in the *Odyssey*.

In the latter part of the 7th century B.C. the Greeks began to colonize the north coast. Between the Cuthaginian territory and the borders of Egypt they planted a number of cities, and the Pentapolis of which Cyrene was the chief was among the richest and most flourishing of all the Greek states (see CYRENE). When the Persians invaded Egypt they made some attempt to extend their empire over Libya, but the expedition of Cambyses (about 525 B.C.) was too unfortunate to encourage them to further efforts. The camel was introduced into Egypt under the Persian rule, and from this time it became easier to make long journeys over the Libyan deserts. Herodotus shows much knowledge of the Sahara, and it is clear that his account must be founded on the reports of traders and caravan guides well acquainted with the desert route. Under the Macedonian kings knowledge of Libya was much extended; they sent exploring expeditions for scientific purposes into Abyssinia, while growing wealth and luxury caused a continually increasing demand for the ivory, spices, and other produce of Libya. In the period 500-200 B.C. it seems certain that commerce was maintained with the countries beyond the Sahara in at least two ways—by the Carthaginian ships trading along the Atlantic coast, and by the overland route across the desert to the Nile. The Roman conquest of Carthage closed the former route. Polybius indeed was commissioned by Scipio to explore the country, and sailed a long way down the west coast; but the Romans themselves had not the maritime enterprise required for such voyages. The record which Polybius wrote for his friend Scipio is quoted by Pliny and Stephanus. Sallust also collected information about the country, and under the emperor Nero an exploring expedition was sent into Abyssinia. The Romans added more to the knowledge of Libya in other ways,—by a better organization of the province and increased facilities of travel and trade, by the frontier wars against surrounding tribes, and finally by the expeditions sent directly into the heart of the country to procure wild animals for the amphitheatre. The passion of the Roman populace for seeing strange animals slaughtered in the public games was gratified by the emperors and magistrates. Enormous numbers of Libyan wild beasts were exhibited in the amphitheatre; even hippopotami and alligators are mentioned. One Roman officer, Maternus, penetrated at least as far as Lake Chad. The *Periplus* of Arrian preserves a record of the trade along the east coast of Libya in the 1st century. In these ways a fairly accurate knowledge of northern Libya was obtained, and Ptolemy could, in the 2d century, construct a good map of Africa as far south as 11° N., though his idea of the shape of the continent further to the south is less accurate than that of Herodotus.

See Ritter, *Erde und Volk*, 1; Haeren, *Historical Researches*, or in the *German Ideen*, vol. II; and the geographical works of Forbiger, Kiepert, Bunbury, &c.

LICATA. See ALICATA, vol. I p. 874.

LICHENS (*Lichenes*) may briefly be defined as cellular perennial plants, furnished with a vegetative system containing gonidia, and with a reproductive system consisting of female thecosporous fruits and male spermatogenous organs. They constitute a distinct class of cellular cryptogams, intermediate between algae and fungi, to

both of which in some respects they present certain affinities. By the earlier authors they were regarded as being *Aeropycnæ* or terrestrial algae, while of recent years they have been viewed by some writers as being *Ascomycetous* fungi. From both of these, however, they are sufficiently distinguished and separated by the special structure of their thallus, by the presence of certain immediate principles proper to their tissues, and by their mode of life and nutrition. Their relations to these neighbouring classes, and their true systematic place, will be best elucidated on considering their structure and its bearings upon some recent speculations.

Structure of Lichens.

A complete lichen consists of a nutritive and vegetative system termed the thallus, and of reproductive bodies borne upon it in the form of *apothecia* and *spermatogones*. Occasionally, however, there is no thallus present (e.g., *Sphaerium*, various *Leclides*, *Endococcus*), in which case the fructification is parasitical on the thalli of other lichens.

1. *Vegetative System*.—The thallus is very variable in external form and colour, as also in internal structure.

1. In external form it presents the following modifications. (a) The *filicæous* thallus, which may be either peltate, i.e., rounded and entire, as in *Umbilicaria*, &c., or variously lobed and lacinated, as in *Sticta*, *Parmelia*, &c. This is the highest type of its development, and is sometimes very considerably expanded. (b) The *fruticulose* thallus, which sometimes is filamentous, as in *Ephebe*, and may be either erect, becoming pendulous, as in *Umea*, *Ramatina*, &c., or prostrate, as in *Alectoria jubata*, var. *chalybeiformis*. It is usually divided into branches and branchlets, bearing some resemblance to a miniature shrub amongst the *Phanerogama*. An erect cylindrical thallus terminated by the fruit is termed a *podetium*, as in *Cladonia*. (c) The *crustaceous* thallus, which is the most common of all, forms a mere crust on the substratum, varying in thickness, and may be squamose (in *Squamaria*), radiate (in *Placodium*), areolate, granulose, or pulverulent (in various *Lecanora* and *Leclides*). In its pulverulent state it is either the rudimentary or the abortive condition of many species. (d) The *hypophloeal* thallus is often concealed beneath the bark of trees (as in some *Verrucaria* and *Arthonia*), or enters into the fibres of wood (as in *Xylographa* and *Aggyrium*), being indicated externally only by a very thin film or maula. To this may also be referred the evanescent thallus which is denoted solely by gonidia sparingly scattered on the stone or wood (as in some *Caliciei* and *Leclides*). This is the simplest form under which lichenous vegetation occurs. These two latter forms of thalli may be either *determinate*, i.e., of a definite shape with a distinct margin or boundary, or *effuse*, i.e., spreading extensively over the substratum with no visible limits. The differences in these forms are no doubt connected with differences in the chemical composition of the thallus. In colour also the thallus externally is very variable. In the dry and more typically state it is most frequently white or whitish, and almost as often greyish or greyish glaucous. Less commonly it is of different shades of brown, red, yellow, and black. These various colours do not originate from any colouring matters contained in the cells themselves, but, according to investigations made by Nylander (see *Flora*, 1879, p. 658) they depend upon such as are deposited in the granulations and cellular walls, whence they appear on the epithallus. In the moist state of the thallus these colours are much less apparent, as the textures then become more or less translucent, and the epithallus usually presents the greenish colour of the gonidia (e.g., *Parmelia Borreri*, *Peltidea apotheca*, *Umbilicaria pustulata*, and pulverulent *Leclides*).

2. The internal structure of the thallus presents two principal modifications, viz., the *stratified* thallus, having its different elements (hyphae and gonidia) arranged in layers, and the *unstratified* thallus, in which these different elements are confused in a homogeneous tissue.

A. *The stratified thallus*.—On making a vertical section this is seen in a foliaceous lichen to consist of three layers, constituting a *cortical*, a *gonidial*, and a *medullary* system, to which in the case of many crustaceous lichens is to be added a fourth, viz., a *hypothalline* stratum.

(a) *The cortical stratum* occupies the whole of the external surface of filamentose and foliaceous lichens, both the upper and under surfaces of some foliaceous and squamulose species, while it is found only on the upper surface of crustaceous lichens. It usually consists of a colourless cellular tissue, in which the cells are closely compacted and form a pseudo-parenchyma. Its most superficial portion, termed by Nylander the *epithallus*, a sort of cuticle, is amorphous, often more indurated and coloured. In some lichens (e.g., *Collema*) it is the only portion of the cortex present, while in pulvulent crustaceous thalli it is entirely wanting. (b) *The gonidial stratum* is situated immediately beneath the cortical stratum, and consists usually of greenish spherical cells, or of granules destitute of a cellular membrane. It is not always continuous, but is often interrupted, the gonidia occurring in disconnected masses. Sometimes it is situated on the upper part of the medullary stratum, in which case the gonidia are arranged either between or amongst its exterior elements. In general its limits may readily be distinguished from the others by its peculiar colour. Various important matters relating to the gonidia will more appropriately be afterwards discussed at length. (c) *The medullary stratum* is more variable in its constituent elements, but, being always colourless, is easily recognized. It presents the three following principal modifications. (a) *The woody medulla* consists of simple or branched filaments, which in foliaceous species are loosely interwoven and entangled, and in crustaceous species are more or less confluent, assuming a longitudinal direction, and constituting, as in *Ulex*, a kind of solid axis for the support of the thallus. (b) *The areolate medulla* occurs only in crustaceous lichens, and is generally characterized by its latticose appearance. It is more compact than the preceding, and consists for the most part of molecular granulations often intermixed with octahedral crystals of lime, and presenting but few traces of filamentous elements. (c) *The cellular medulla* consists of a tissue of angular, rounded, or oblong cells containing gonidia in their interior or in their interstices (e.g., *Pannaria*, *Endocarpon*). In some species (e.g., *Pannaria fuscula*) the cells have a tendency to reemit into filaments and then to separate again into rows of cells. (d) *The hypothalline stratum* is the inferior one of the thallus and that upon which the other strata are developed, though it is not always visible, and is sometimes entirely wanting. It usually presents itself under a twofold aspect, viz., the *hypothallus* and *rhizoma*. (a) *The hypothallus* proper, which is immediately developed upon the prothallus (i.e., the filaments of the gametangial sporae), is a horizontal stratum consisting of interlacing filaments of elongated, short, or round cells, and is sometimes of a white or whitish colour, but usually dark or blackish. In many crustaceous lichens it is represented only by a black or dark-colored border limiting the thallus (e.g., *Leucidea geophila*, &c.). (b) *The rhizoma* consist of vertical branched filaments, usually branching and tapered at their extremities, blackish or greyish in colour, rarely white, which occur on the lower surface of foliaceous lichens. They consist of several filamentous elements which are most frequently articulated and agglutinated (e.g., *Pannaria*, *Physcia*), or sometimes simple and then always articulated (e.g., *Stictis*). It is to be observed that the hypothallus and the rhizoma are merely as bases of attachment for the lichens to the substratum, and do not in any way aid in its nutrition.

B. *The unstratified thallus*.—This occurs amongst the *Lichenes* (which, however, are most frequently stratified as above), and in

FIG. 1.—Section of Stratified Thallus of *Rosellea baccata*. a, cortical stratum; b, gonidial stratum; c, medullary stratum.

various species belonging to the inferior genera, which have a pulvulent or hypophloeal thallus. In these the cortical elements are more or less mixed together, though the gonidial stratum generally remains distinct, and is often visible when the others are absent. It is, however, the families of the *Physcia* and *Collema* that are more especially characterized by an unstratified thallus. Here the cortical stratum is chiefly represented by a gonophore (in *Collema*), rarely brown (in *Synalassa*, &c.), non-cellular epithallus, or in others (*Lepogium*) by a thin stratum of angular cells distinct from the other elements of the thallus. The gonidial granules are also disposed in a different manner to those of the *Lichenes* in the majority of the

Collema species they are strung together moniliformly, and distributed in a thread into a gelatinous pellucid substance, while sometimes they are agglomerated into small groups, and situated for the most part next to the epithallus. In *Ephraea* they are not moniliformly strung, but are tuncated or involved in a gelatinous cellular stratum. The rest of the thallus consists of the medullary system (except in *Ephraea*, in which there is no medulla), and is composed of tubular or hollow filaments, with rounded cavities containing the gonidial granules, and imbedded in the gelatinous substance, which very readily imbibes water. There are a few lichens in which there is no trace whatever of stratification, as the genus *Cacoecoporus*, in which the entire thallus is composed of filamentous membranous elements, and the peculiar family of the *Myurocladia* (formerly, however, referable to lichens), in which it is equally cellulose throughout.

In addition to the hyphal and gonidial anatomical elements which thus enter into the structure of the thallus, there is another to be noticed, which, however, is to be regarded rather as an immediate principle. This is the *molecular granulations*, which are extremely small and (in form) irregular corpuscles, 0.001–0.002 millim in diameter, and visible only when very highly magnified (300–400 diameters). They occur in all parts of the thallus, especially in the younger cells, from the epithallus to the hypothallus, being especially abundant in the medulla of crustaceous species. In the epithallus they are variously coloured according to the colour which it presents, but in all other parts they are colourless. They occur also in the apothecia, in the epithecium, in the spores, and constitute the famous “*microgonidia*” of Dr. Munk. By the application of sulphuric acid many of them are transformed into small acicular crystals, and in the spores they are frequently agitated by a Brownian movement.

We may here also, in connexion with the vegetable system of lichens, refer to certain peculiar *excrecences* which are sometimes presented by the upper or under surface of the thallus. Of these the principal are the following: (1) *Soredia* are pulvulent eruptions on the cortical stratum, varying in form, being rounded or diffuse, and either are scattered upon the upper surface of the thallus or border its margins. They are of a lighter colour than the thallus, and consist of a mass of gonidia and of molecular granulations intermingled with filamentous elements. They occur in many foliaceous, foliaceous, and crustaceous lichens, and their protrusion through the cortical stratum is owing most probably to an excessive development of the gonidial element. Occasionally also they appear on the disk of apothecia (in *Pezizomora*), which they render lobulate, and in this case constitute the pseudo-genus *Varicaria* of older authors. When detached from the thallus they are capable under certain favourable circumstances of giving rise to new plants, and thus act the part of bacilli in the *Phaeogameta*. It is denied by their means that many species which are never found in a fertile state (e.g., *Thamnochrysa verruculosa*) are propagated. (2) *Cyphellae* are small, ureolate, pale excrecences which occur abundantly on the under surface of many species of *Stictis*. They are generally naked, but are often also pulvulent or sorediferous.

FIG. 2.—Section of Unstratified Thallus of *Collema conopseastrum*, with Moniliform Gonidia scattered amongst the Epithallic Filaments.

in which latter case they are called *pseudo apothecia*. That physiological function is not definitely known, but they are most likely connected with the nutrition of the plants. (3) *Isidia* constitute an evanescent condition of some foliaceous and crustaceous thalli. They consist of peltate, conical, stipitate excrescences, which are sometimes branched, and which are always of the same colour and texture as the thallus itself. This rudimental condition in crustaceous thalli is the basis of the old pseudogenus *Isidium*, which is merely an anomalous state of some species of *Peltularia*. *Isidia* have the same functions as the soredia, and serve as propagula. (4) *Cyphella* are orbicular and flattened or globose tubercles of a peculiar texture which occur on the thallus of many species belonging to different genera. They are usually gregarious, as in *Stereocaulon*, *Ulex*, *Lecanora gelata*, *Lecanora pinnatifida*, &c. In a few species, however, they are hygienous, as in *Peltularia canos* and *Pseudocyphella*, while in various *Ulex*, *Sphaerium capitatum*, &c., they are endogenous, bearing prominent protuberances on the lower surface. Recently Nylander has detected both endogenous and hygienous cyphella on *Parmelia asperum* and *Lecanora obtusata*. They are of a pulvinate colour than the rest of the thallus, from which they differ also in structure, being completely collimate, and containing gonidial granules. According to Th. M. Fries (*Flora*, 1896, p. 26) they are also normal excrescences caused by algae intruding themselves under the cortex, but this is at once refuted by the fact of their forming constant characters of so many different species occurring in various situations. In which they evidently constitute normal organs, the use of which, however, is unknown.

II. *Reproductive System*.—This consists of *apothecia* or the female organs, of *spermatogones* or the presumed male organs, and probably also of *gonodes* or a secondary kind of fructification.

1. The apothecia, like the thallus, are very variable in external form and colour, as also in their internal structure. In external form they present three principal modifications, viz. (1) *disciform* (or gymnocarpous), in which the shape is that of a disc (as in all the higher genera), (2) *nucleiform* (or angiocarpous), in which the shape is that of a rounded tubercle with an apical ostiole (as in *Entoloma*, *Pezizacanthus*), and (3) *peridioform*, similar in shape to the preceding, but closed, with no ostiole (as in *Thelecia*, *Entolomaceae*). The last two are but little variable in figure, and consequently do not in this respect admit of different designations. The disciform apothecia, however, present various shapes, of which the following are the principal:—(a) *peltate*, which are large, rounded, without any distinct thalline margin (e.g., *Ulex*, *Peltigera*), (b) *lecanorine*, or scutelliform, which are orbicular and surrounded by a distinct, more or less prominent thalline margin (e.g., *Parmelia*, *Lecanora*), having sometimes also in addition a proper one (e.g., *Thelotrema*, *Ureolaria*); (c) *lecidine*, or patelliform, which are typically orbicular, with only a proper margin (e.g., *Lecanora*), sometimes obsolete, and which are occasionally irregular in shape, angular or flexuose (e.g., *Lecanora jurana*, *L. myrmecina*), or complicated and gyrose (e.g., *Gyrophora*), and even stipitate (e.g., *Boxomyces*); (d) *irregular*, which are of very irregular figure, elongated, branched or flexuose, with only a proper margin (e.g., *Xylographa*, *Graphis*, &c.) or none (e.g., some *A. thecia*), and are often very variable even in the same species. It may be here observed that young disciform apothecia are more or less nucleiform. In colour the apothecia are extremely variable, and it is but rarely that they are concolorous or subconcolorous with the thallus (e.g., *Ulex*, *Rinodina*). Usually they are discolorous, and may be black, brown, yellowish, or also less frequently rose-coloured, rusty-red, orange-reddish, saffron, or of various intermediate shades. Occasionally in the same species their colour is very variable (e.g., *Lecanora metaboldes*, *Lecanora decolorans*), while sometimes they are white or glaucous, rarely greenish, pruinose. Lecidine apothecia, which are not black, but otherwise variously coloured, are termed *isotoma*.

The two principal parts of which an apothecium consists are the *hypothecium* and the *thecium*.

(1) The *hypothecium*, which corresponds to the hypothallus, is the conceptacle of the apothecia. It is composed of cellular tissue, generally very dense, and often presenting an indistinct stratification. This tissue may in general be distinguished from that of the neighbouring parts of the thallus by its cells being smaller, more compact, and differently coloured, though in some instances (as in certain *Parmelia*) the limits are not determinable. In the apothecia of such genera as *Collema*, *Boxomyces*, &c., the hypothecium is composed of hollow cemented filaments arranged longitudinally and constituted into a stipe for the support of the fruit. The hypothecium in disciform apothecia is usually termed the *excipulum* proper, while in nucleiform apothecia it is termed the *pyrenium*, and in peridioform apothecia the *peridium*. When the pyrenium quite covers the nucleus it is said to be *calcareo*, *dissimulate* when it covers only the upper portion. The hypothecium is either colourless or dark, or reddish or yellowish, according as its cells are tinged.

(2) The *thecium*, or as it is more frequently termed the *apothecium*, is that part of the apothecium which contains the organs of the fruit, viz. the *thalamium* and the *theceae*, which are placed perpendicularly to the hypothecium. It is penetrated by an amyloid substance, colourless and very sticky of water, termed the *hypocaulic gelatin*, formed of the gelatin, which becomes bluish or wine-reddish when tinged with colour. The thecium itself corresponds to the gonidial-membranous stroma, while its superficial portion, termed the *epithecia*, corresponds to the epithallus. (a) The thalamium generally consists of paraphyses which are erect colourless filaments arising from the hypothecium, and whose function is to aid in the expulsion of the spores by the pressure which they exert upon the thecae. They are of nearly equal height, closely placed together, usually very slender, though slightly variable in thickness, frequently attenuated, and rarely branched or anastomosing. Internally they are hollow and filled with prothallium, which sometimes is separated into little globules. Their spores are generally coloured, in most instances dilated, sometimes clavate, and are cemented together by gelatin. They are frequently confused together, occasionally they are but little evolute, while in many of the *Pyrenopezizae* they are entirely wanting, though in these the ostiole filaments of the hypothecium leave sometimes been mistaken for them. (b) The thecae are large, oblong, cylindrical or ovoid cells or vesicles containing the spores, and are usually more or less attenuated towards the base. In size and shape they vary considerably in the different genera and species according to the size, number, form, and arrangement of their spores. They differ also in the same species, within certain limits, according to age, the young thecae being more slender than those which are older. In some genera which have very large spores (e.g., *Parmelia*, *Pezizacanthus*) the thecae are distended in proportion, and generally present a sacrate or subglobose-vesiculate form. The theca itself is a thin membranous cellule, the walls of Pro 3.—Vertical Section of Apothecium of which are at first of *Physcia patens* a, paraphyses, b, an equal thickness throughout, but in process of development they become gradually thinner, except at the summit, where they retain their original thickness. In some species the wall is remarkably thick at the apex (e.g., *A. thoma*), and in others it is invested throughout with a kind of external crust (e.g., *Pezizacanthus*). The thecae are resorbed after the expulsion of the spores, though where their walls are extremely thin (as in *Collema*) they are ruptured and disappear at a very early stage. The spores are the special reproductive organs of lichens, and are produced in the thecae by free cell-division, i.e., by the separation and subsequent condensation of the protoplasm of the fully developed sporangia around central points in its interior, corresponding in number to that of the spores to be formed. After the formation of the external spore-wall has taken place, the spores have a definite outline, and may consist of only one cellule or loculus (simple spores), or may be divided by one or more transverse peritremes (septate spores). Sometimes the loculi are restricted to the two ends or poles of the spore (one in each) and are said to be *polari-locular*, the two loculi being occasionally united by a longitudinal tube. At other times the transverse partitions are further divided by several longitudinal partitions, in which case the spore is said to be *murally-divided*, from the resemblance it then bears to the stones in a wall. The contents of the spores are

Pro 3.—Vertical Section of Apothecium of which are at first of *Physcia patens* a, paraphyses, b, an equal thickness throughout, but in process of development they become gradually thinner, except at the summit, where they retain their original thickness. In some species the wall is remarkably thick at the apex (e.g., *A. thoma*), and in others it is invested throughout with a kind of external crust (e.g., *Pezizacanthus*). The thecae are resorbed after the expulsion of the spores, though where their walls are extremely thin (as in *Collema*) they are ruptured and disappear at a very early stage. The spores are the special reproductive organs of lichens, and are produced in the thecae by free cell-division, i.e., by the separation and subsequent condensation of the protoplasm of the fully developed sporangia around central points in its interior, corresponding in number to that of the spores to be formed. After the formation of the external spore-wall has taken place, the spores have a definite outline, and may consist of only one cellule or loculus (simple spores), or may be divided by one or more transverse peritremes (septate spores). Sometimes the loculi are restricted to the two ends or poles of the spore (one in each) and are said to be *polari-locular*, the two loculi being occasionally united by a longitudinal tube. At other times the transverse partitions are further divided by several longitudinal partitions, in which case the spore is said to be *murally-divided*, from the resemblance it then bears to the stones in a wall. The contents of the spores are

a homogeneous protoplasm, molecular granulations (often abundant), and a pale-yellow oily substance, which in the fully developed spore often becomes concentrated into one or more globules, visible generally near its ends or in the middle. The number of the spores in each thallus varies very much in different species, being in most lichens 8, occasionally 6, 4 or 2, or rarely only 1. In some species, however, they are 20-100, when the thallus is said to be *polysporous*. In form they are also very variable, the principal shapes assumed by them in order of frequency being *ellipsoid*, *fusiform*, *oblongo-cylindrical*, *spherical*, and *acicular*, with several intermediate forms. They are still more variable as to size, being smallest in polysporous (e.g., *Leucospora funaria*, etc.), and largest in monosporous species (e.g., *Peltigera consimilis*, Ra.). The largest spores of all are found in *Pezizella in amica ostrea*, where they are 0.225-0.030 millimetre long, and 0.035-0.115 millim thick. As to colour, they are either *colourless* (white, nearly hyaline or pale yellow under the microscope), or *coloured* (brownish, or brown, or blackish), while in *Sphaerophorus* there is also a blue-black superficial pigment. The spore-wall varies in thickness, and is typically composed of two strata, the outer of which is termed the *exospore* and is coloured, while the inner is termed the *endospore* and is colourless, gelatinous, and generally less distinct. Notwithstanding that in these respects the spores are so variable in different species, they are when mature remarkably constant in the same species, so that their characters afford valuable specific diagnoses. Apparently it is only those lichens which germinate from spores that occur in a futile condition.

2. The *spermatogones*, which are the presumed male organs of reproduction, at once differ in appearance from the apothecia in being very minute corpuscles. In many cases their outline is invisible to the naked eye, unless the thallus has been previously moistened, when they appear as minute points or papillae. When magnified they externally bear a resemblance to the apothecia of the *Pyrenopezices*, but internally, on microscopic examination, they are seen to differ essentially from these. In form they are nucleiform, round, or oblong, and are either sessile on the surface of the thallus, or more or less immersed in its substance, or sometimes enclosed in prominent thalline verrucae. Usually they are simple, though occasionally two or several become confluent or aggregated into little groups. They almost always occur on the same thallus as the apothecia, or rarely on different thalli (e.g., *Ephebe pubescens*), so that lichens are consequently monocious or dioecious. In colour the spermatogones are black or brown, or concolorous with the thallus itself. They are composed of two parts, viz., a shell or *conceptacle* and a *nucleus*.

(1) The *conceptacle*, which is analogous to the hypothecium of the apothecium, is composed of a tissue formed of very small cells, which are cemented together and have thick walls. The orifice at its summit is generally similar to that of nucleiform apothecia, and in the case of entirely immersed spermatogones is the only portion visible.

(2) The *nucleus* consists of the *stergmata* and *spermatia*, and of a mucilaginous substance (the spermatine gelatin) in the cavity between them, which very greatly imbibes water and aids in the expulsion of the spermatia. Sometimes also there are present in the nucleus a few elongated, articulated, and occasionally branching filaments intermixed with the stergmata which are comparable with the paraphyses of the apothecia (e.g., *Ramalina*). (c) The *stergmata* are elongated cells filled with a colourless fluid, and are attached to the interior face of the conceptacle growing from it convergently towards the centre, and often nearly filling its entire cavity. They present two important modifications, viz., *simple stergmata* and *articulated stergmata* or *arthrostergmata*, both of which may become somewhat branched. When arrived at maturity they possess the faculty of producing from their apices or also from the articuli the spermatia, one at a time, though many in succession, as may be inferred from the immense number of them lying in the cavity of the nucleus. (d) The spermatia are very small, slender, colourless corpuscles, which at first appear as minute pectinuous on the apices of the stergmata cells. They subsequently become gradually elongated, and, on reaching maturity, detach themselves from the stergmata and lie free in the cavity of the nucleus, till in wet weather they are expelled through the ostiole of the spermatogone. In form they present two principal modifications, viz., *acicular* and *ellipsoid*, of which the former, the more frequent, is rather variable. They may be slightly unisiformly-increase at one apex (e.g., *Usnea*), or at both apices (e.g., *Paraselia*), or they may be cylindrical and straight, the most common shape, or cylindrical and arched (e.g., *Roccella*). The spermatia of arthrostergmata are cylindrical and straight, but slightly thickened and obtuse at the

apices. In size they also vary, though more in length than in thickness, the aciculate spermatia being sometimes very long (0.040 millimetric). These differences in form and size are often very useful in the discrimination of species, just as the two types of the stergmata are sometimes of great service in the distinction of genera. The spore-

Fig. 4.—Vertical Section of a Spermatogone of *Pezizella physodes*, showing the Stergmata and Spermatia.

ma frequently exhibit a Brownian movement, but they possess no faculty of germination, their functions as generally acknowledged, being the fertilization or fecundation of the spores. That the spermatogones are rightly presumed to be the male organs of reproduction may legitimately be inferred alike from their relation to and their antagonism with the apothecia. In the former respect their position on the thallus relatively to the apothecia is similar to that of the sexual organs in other classes of plants, while in the latter respect spermatogones are plentiful on thalli destitute of apothecia, and on those with apothecia are much more sparingly present. The manner, however, in which the spermatia impregnate the spores has not yet been definitely ascertained. Most probably, as suggested by Nylander (in *Syn.*, p. 40, note 1), the spermatia do not exercise any direct influence on the female organ in the hymenium, but their fecundating influence is rather exercised on the prothalline elements of the growing thallus. M. Stahl indeed has recorded and illustrated (*Beitr. zur Entwick. der Flechten*, 1877) the results of certain researches on *Collema atro-ophyllum*, in which he supposed that he had detected sexual organs in the shape of an *ascogonium* and a *stichogonium*, regarded by him as a kind of *crotopogonium*. These observations, however, have not been confirmed by subsequent researches on the same or any other species of *Collema*, while his attributing to the hyphae a faculty of "concoction" or equally cooking themselves, which from their nature they do not and cannot possess, is calculated to invalidate all that he otherwise observed and depicted.

3. The *pycnodes* are minute, dark-coloured pyrenoidous conceptacles which occur on the thallus of various lichens, especially such as are crustaceous. In external appearance they resemble to some extent the spermatogones, from which, however, they at once differ in their internal organization. They consist of simple filaments composed of narrow (often short) cells, termed *bandae*, bearing on their apices bodies called *tylospores*, which are colourless, usually oblong, but variable in form and size, and filled with organic matter (in part at least only) similar to thespores. Each basidium produces only a single tylospore, which, unlike the spermatia, has a germinative property. Their occurrence in lichens was first pointed out by Tulane, who showed their affinity to certain analogous fruits (*Diplodia*, *Phoma*, *Sporium*, &c.) in various thecaepored fungi, and regarded them as supplementary or secondary sponiferous reproductive organs. Considering the number of parasitic *fungilli*

which frequently occur on lichens, it might be supposed that the pyrenides in reality belonged to the same category. From their constant occurrence, however, on the same

FIG 5.—Fronds of *Peltigera rufescens* a, basal; b, stylous.

states of *Peltigera rufescens* and *P. rufescens*, where they have often been mistaken for spermatophytes, which in this genus have not yet been detected. Pyrenides occur also in *Leccaria rufescens*, and abundantly in *L. tinctella*, in *Urocladus*, in several species of *Stictis*, in *Sporopodium reverens*, and will probably be yet observed in other lichens.

The Gonidia of Lichens.

In view of the important place occupied by the gonidia in the structure of lichens, and of the discussions that have recently taken place concerning them, they require to be considered somewhat in detail in order that their real nature and relation to the hyphae, or the thalline filaments, may become apparent. The gonidia are spheroidal, ellipsoidal, or variously rounded cells, with thin, colourless walls composed of cellulose, containing chlorophyll (or a submineral colouring matter), homogeneous or granular, with generally a solid nucleus in the centre. As to the origin of the chlorophyll, it may be observed in passing that this is the same in lichens as in other cryptogamic plants, e.g. mosses and *Hepatica*, in which it occurs, the only visible difference being that gonidia often occur as discrete cells. The gonidia increase by binary (very rarely by ternary or quaternary) division, the nucleus also dividing into two portions, each of which forms the centre of a secondary gonidial cell. In this gonidial stratum, where they are arranged between the radicles of the hyphae, their division necessarily proceeds only slowly, but in ecoriated thalli, hepatic and others, in which they are free, they are readily multiplied by repeated division. In gonidia isolated from the thallus of some species belonging to *Cladonia*, *Evernia*, and *Physcia*, zoospores have been detected by M. Faminitzin and M. Boranetzky (see *Ann. Sc. Nat.*, 1868, p. 137), and, although Nylander failed to perceive such in subsequent experiments (*Flora*, 1877, No. 23), he adds that it is possible they may be generated in free gonidia (i.e., in unstratified thalli), which could not be the case in gonidia closely surrounded by thalline filaments. The subject will well repay further investigation. Other matters relating to the character and relations of the gonidia will be best elucidated by considering the forms which they present, and their origin in the thallus.

1. *The Forms of the Gonidia*.—These have been fully treated by Nylander in the *Flora*, *loc. cit.*, where also the first scientific description and classification of them have been given. According to the views there propounded, gonidia in their wider acceptance include three very distinct types.—(1) *Ergonidia* (or gonidia proper), which are involved in a distinct cellular membrane, and are usually bright green, (2) *Gonatae* (or the gonidial granules already mentioned), which are naked, pale greenish, glaucous greenish or bluish, and (3) *Gonidia* (or *Leptogonidia*), which are intermediate between the two preceding, smaller, and of an oblong form. Of these the distinction between *ergonidia* and *gonatae* is fundamental, and of "so great weight that lichens seem to present a twofold parallel series" according to the presence of the one or the other in their texture.

These two distinct anatomical elements, as observed by Nylander, have a certain biological analogy with the blood globules in animals, and similarly afford absolute characters. The principal forms presented by these three kinds of gonidia are the following: 1. *Ergonidia* consist of—(a) *Hypogonidia*, the most frequent, simple, of a protracted form, or sometimes globose (as in *Sciaropsis leprosa* Thall.), (b) *Phragmogonia*, being depressed and variously prominently ornamented gonidia (*Synagoga*), as in some foliose species (e.g. *Peltigera* *phylosum*), (c) *Chlorogonidia* (or *Chlorogonidia*), containing chlorophyll and orange granules (endotheca) in the same cells, more or less similar to *chloridia* (as in *Chloridia chloridia*, *Arthonia prunella*, *Platyphaga pilosa*, *Vericaria* *insularis*, and the genus *Tholera*), (d) *Confertogonidia*, somewhat resembling *Confertia*, and forming the chief element of the thallus of *Crotophaga*. 2. *Gonatae* are smaller than gonidia proper, with the wall of the cell less distinct. They occur in *Peltigera*, *Sclerophora*, and *Arthonia crystallina*. To these belong also *lyngbyoid gonidia*, which are often very minute, and are present in the thallus (not in the perithecia) of various *Pyrenopeziza* (e.g. *Pyrenopeziza pallida*, *P. umbellata*, and *P. lyngbyoides*), rarely of *Arthonia* as in *Arthonia* *chrysoidea*. 3. *Gonidia* (including the gonidia of *Chloropoda*) consist of—(a) *Hypogonidia*, which are somewhat large (very large in *Phyllopora*), and either simple, or two or several aggregated, (b) *Synagoga*, which are spheroidal or spheroidal gonidia, distinguished by the gonium being truncated, and are characteristic of the family *Ethecaria*, (c) *Horogonidia*, the most common form, smaller, moniliformly arranged, and contained in synagoga, especially characteristic of the family *Collema*, whence *Collema* (or *Nostoc*) itself, according to Nylander, is to be considered but as a single synagoma, (d) *Sperogonidia*, which are similar to the preceding, but are not moniliform, with the synagoma subglobose, smaller and more scattered, as in *Gompholoma* and *Synagoga*. It will be perceived from the above that many of these forms are more or less similar to "gonidia" as *algae*, though, as we shall presently see, they are not identical with these.

II. *The Origin of the Gonidia*.—By pre-microscopic authors this was a subject necessarily ignored, and indeed it is only within the last thirty years that it has been investigated, by its help as the easiest thing as to this origin was that put forward by Bory de Saint-Vincent (*Revue sub d. Lichens*, and *deux* *Revue*, 1851), confirmed by observations of Sphaerocarpus (*Bot. Zeit.*, 1858, &c.), and supported by Schweinichen (*Unterz. sub d. Flechtengonien*, 1868). This was to the effect that the gonidia derived their origin from the hyphae (i.e., the thalline filaments), in the way commonly described by M. Fries (*in Staat*, 1871, p. 7, where it is fully enclosed). "The hyphae," he says, "are not only elongated into filaments, but also put forth short branched, the terminal cell of which is gradually dilated, becomes subglobose, and is at length filled with chlorophyll (or a submineral matter), in the way commonly described by M. Fries into a gonidium, and then by varied division generates other gonidia." For several years this theory was accepted as second-hand by most authors who referred to the subject, though a different origin of the gonidia, presently to be noticed, was indicated by the celebrated Tulasne so early as 1852, in his "Mémoire sur les lichens" (*Ann. Sc. Nat.*). The erroneous nature of this theory was well pointed out by Schweinichen, who (*Die Agenten d. Flechtengonien*, 1868) very correctly affirmed that the actual development of a gonidium from the terminal cell of a hypha had not been observed, though, strange to say, he had previously himself observed this phenomenon. Not being able otherwise to account for the origin of the gonidia, and following up one of the alternatives put forward by De Bary (*Morpholog. und Physiol. der Pilze, Flechten*, &c., 1865, p. 201), he promulgated the hypothesis now familiarly known as Schweinichenism. The conclusion to which De Bary came on noticing the resemblance between the gonidia of *Collema* and certain algae was as follows: "The origin of the lichens in question," he says, "are the perfectly developed states of plants, whose imperfect forms have hitherto stood amongst the algae, as *Nostoc* and *Chroococcoides*, on these latter are typical algae which assume the forms of *Collema*, *Ethecaria*, &c., through certain parasitic *Ascomycetes* penetrating into them, spreading their mycelium into the continuously growing thallus, and finally attaching to their phycochrome-bearing cells." Taking this latter suggestion as his starting point, and assuming the identity of certain algal types with the gonidia of lichens, and the identity of the mycelium of fungi with their hyphae, Schweinichen extends the said alternative to various other groups of lichens than the *Collema*, and comes to the conclusion that a lichen is composed of a parasitic fungus (the hyphae) and a number of low algae (*Chlorophytales* and *Phycococcaceae*), the former of which produces the reproductive bodies and is nourished by the latter. This theory was subsequently expanded and illustrated at length by Bornet (*Recherches sur les Gonidies des Lichens*, 1879), and has since been the subject of numerous investigations, "that the connection of the hyphae with the gonidia is of such a nature as to exclude all possibility of the one organ being produced by the other," and that the theory of parasitism can alone explain it satisfactorily. To give any detailed

account of the investigations of these authors, and the arguments by which they endeavor to support the hypothesis, would exceed the limits of the present article, even were all other matters relating to lichens to be excluded. Suffice it to state briefly that, according to Schwendenerism, a lichen is not an individual plant, but rather a community made up of two different kinds of individuals belonging to two distinct classes of organisms, viz., a master-fungus and colonies of algal slaves, which it has sought out, caught hold of, and retains in perpetual captivity in order to provide it with nourishment. To such a singular theory, which from its plausibility has met with considerable support in certain quarters, various *a priori* objections of great validity may be taken. Amongst others which have been adduced it may especially be noticed, having reference to the nature of this alleged parasitism, and the situations in which lichens are found. (1) The parasitism described is of a kind unknown in the vegetable kingdom, inasmuch as the host (the *Algae*), instead of suffering any injury, only flourishes the more vigorously. Moreover, the algal slaves being entirely enclosed in the master-fungus, can evidently supply no nourishment to it whatever, while direct observation shows that it is through the surface of the thallus of the lichen that nourishment is conveyed to the gonidial statum, where the active life chiefly has its seat. (2) As is well known, lichens attain such habitats as are most frequented by algae and fungi, and occur in situations where neither of these are seen. Where then are the algal colonies which, according to the hypothesis, the fungus goes forth in quest of, and "picks into its service"? Each of these arguments is sufficient to throw more than doubt upon Schwendenerism. At the same time, as will be perceived, the origin of the gonidia in the thallus remains to be accounted for, in order that the hypothesis may be utterly subverted. It might at first sight be supposed that this was a matter of no very great difficulty, since by cultivating lichens from the spores it would readily become apparent. All attempts, however, in this direction (and many such have recently been made) have, owing to the peculiar character and conditions of lichen-growth, confessedly proved futile, and the experiments instituted have been productive of no definite results. This is not altogether to be regretted, since in nature itself, when lichens occur on certain substrata, we have in various instances the whole process of the evolution of their vegetative system placed before our eyes, from the first germinations of the spores to the formation of the perfect thallus. It is to Nylander, whose services here are elsewhere in lichenological science—statistical, physiological, and systematic—are so valuable, that we owe the first clear enumeration as to the origin of the gonidia in the lichen-thallus. This, though previously indicated by him, as we shall presently see, was at greater length and still more doubtfully stated in several important papers in the *Floa*, viz., "De gonidiis et eorum formis animaliversionibus" (1877, No. 23), "Citra lichenes vitulosus natum" (1878, No. 10), and "De hypothallo natum" (1879, No. 36). In these he incontrovertibly demonstrates that the gonidia originate, not from the filaments themselves, but in the cellules of the first cortical gromesules which are produced upon the young hypothallus. This may very easily be studied in the earlier stages of development of crustaceous lichens growing on pure quartz rocks (e.g., *Leccaria vagophylla*), on the smooth bark of young trees (e.g., *Leccaria subulæ*), and more especially on the surface of old glass (e.g., *Leccaria galactina* and *Leccaria albobata*). In the case of the young thalli of *Leccaria anversa* this was sufficiently well demonstrated by the celebrated Tulane in 1863, the year subsequent to the promulgation of the Bayrholferian theory, in his elaborate "Mémoire sur les Lichens," pl. III. f. 8. Afterwards, as the evolu-

tion of the cortical statum advances, its lower portion is resolved, and the gonidia there become free, giving rise to the gonidial statum, to the hyphae in which they are not *obscure*, as has been represented, but only adherent by means of the gelatin which penetrates all the elements of the lichen. Often also growing gonidia, young and adult, may be observed in the pseudo-parachymatous cortical cellules in lichens which in this respect are best adapted for examination, such as *Umbilicaria* (vide Nylander in *Floa*, 1875, p. 303), *Physcia putrescens*, *Pannaria hypogyna*, &c. Similarly, with respect to the origin of the gonidia, Nylander observes (*Floa*, 1868, p. 353) that the nuclei in the *Collenchyma* (more especially in *Collenchyma*) "show very clearly under the microscope the entire history of the evolution of the thallus from its first origin from a cellule containing a single gonium to a minute true nodule, and ultimately to the perfect texture of a *Collenchyma*." With these facts before us, to which various others might be added, such as the entire absence of any algal on pure substrata, where lichen growth presents itself in all its stages, we are compelled to come to the conclusion that the gonidia constitute a true gonial system in lichens, and in nature are nowhere seen outside the thallus. Consequently these free algal forms, such as *Protococcus*, &c., regarded as the free gonidia of lichens, are true algae, these being indeed a parallelism between them but no identity. On the other hand, as the alleged identity of the lichen-hypha with a fungus-mycelium, it is to be observed that the two are totally different in their nature. The hyphae of lichens (*mycelophyses* of Nylander) are rigid, elastic, containing lichenine, not becoming putrid by maceration, with no facility of penetrating or involving, while the hyphae of fungi are colourless, soft, flexible, with thin walls, &c. Hence, as there is no algal in the lichen, so neither is there any fungus, though there is a parallelism between the fructification of lichens and the asciferous section of fungi (Columbs in *Pap. St. Bot.* 1874).

Nutrition and Life of Lichens

As already intimated, lichens derive their nourishment directly from the atmosphere, in the shape of rain (or dew) with the materials contained in it. Here, as elsewhere, water is the condition of life, and through its medium is conveyed to them the nutrient substances requisite for their existence and growth, from the clouds, from rivers, and, in the case of maritime species, even from the sea. Where, however, the atmosphere is impregnated with smoke, soot, or other deleterious ingredients, lichens will not grow nor flourish. Hence in our larger cities, or even in smaller manufacturing towns, scarcely any lichen vegetation, or none whatever, is seen. Even in their more immediate suburban districts they occur only in a gonidial or rudimentary state, constituting the pseudo-genus *Lepraria* of the older botanists, and increasing through long periods by bisection, but never developing into perfect plants. Indeed it is now a well-known fact that their fully developed condition is a sure indication of the purity of the air and the salubrity of the districts in which they occur. It has sometimes been stated that they draw some portion at least of their nutriment from the substratum to which they are affixed. For this, however, their structure is by no means well adapted, and such inorganic substances as iron and lime, which enter into their composition, are only as if mechanically derived in solution from the substratum. This in very many instances, e.g., bare quartzose rocks, dead splashed wood, and pure naked glass, can evidently supply no nutriment whatever. Moreover, in the case of crustaceous species, such as *Leccaria tartarea*, &c., and also of terricole fruticose species, such as *Cetraria islandica*, &c., the portion of the thallus next to the substratum is dead, so that no nutrient substances can be conveyed through it to the upper layers of the thallus. A very simple, but at the same time convincing, illustration of this is adduced by Nylander. "By immersing," he says, "any fruticose thallus, such as *Ulex*, by the base in water, it remains entirely dry (with the exception of the part submerged), but if water be poured over the other portions, it quickly absorbs it, softens, and revives." The same thing may be seen in nature itself, in the case of such species as *Cladonia rangiferina*, *Alectoria ochroleuca*, *Platyisma rivale*, &c., growing on temporarily wet substrata,

FIG. 6.—Hypothalline condition of *Leccaria anversa*, showing the origin of the first Cortical Gonidigenous Cellules (After Tulane) 36. In these he incontrovertibly demonstrates that the gonidia originate, not from the filaments themselves, but in the cellules of the first cortical gromesules which are produced upon the young hypothallus. This may very easily be studied in the earlier stages of development of crustaceous lichens growing on pure quartz rocks (e.g., *Leccaria vagophylla*), on the smooth bark of young trees (e.g., *Leccaria subulæ*), and more especially on the surface of old glass (e.g., *Leccaria galactina* and *Leccaria albobata*). In the case of the young thalli of *Leccaria anversa* this was sufficiently well demonstrated by the celebrated Tulane in 1863, the year subsequent to the promulgation of the Bayrholferian theory, in his elaborate "Mémoire sur les Lichens," pl. III. f. 8. Afterwards, as the evolu-

when the base of their thalli is soft and moist, and all the rest dry and rigid. It cannot therefore be doubted that the nutritive elements contained in the rain or other water are conveyed to the lichen through the surface of the thallus. It is in the superficial parts also, as Nylander has well observed (in *Flora*, 1874, No. 4), that "the active life has its seat, chiefly around the gonidia, manifesting itself in the putting forth of young parts (lobes, lacinae, branches, isidia), and in the functions of the apothecia and the spermatogones, so that the nourishing humours necessary for all the actions of life are especially and directly poured upon these." The vital activities, however, in lichens thus nourished are, as might be expected from the nature of the source whence their nutriment is derived, very intermittent, and in dry weather cease to operate, and become entirely dormant. Hence their life, unlike that of all other plants, is twofold, viz., one *active*, in which when moistened all the vegetative and reproductive functions are at work, and the other *passive*, in which when dry these functions are completely in abeyance. For such a peculiar duplex existence, at one time vegetating, at another lethargic, their organization in all its parts, gonidial and otherwise, is admirably adapted. More especially is this the case with respect to the lichens found in their textures, which, being readily dried and as readily moistened, enables them to resist with impunity the greatest extremes of temperature, alternate periods of drought and wet, the scorching heat of the sun, the vehemence of stormy winds, and the nipping frosts of winter.

In this fitful and abnormal life of lichens we have the explanation in a great measure of their almost indefinite duration of existence. It is well known that they are perennial plants in the widest sense of the term, and that, though in the earlier stages of their existence their growth is comparatively rapid, yet this becomes extremely slow when they arrive at a certain age. The time required for the development of even the most rapidly growing species may be calculated by the appearance of such of these as are met with on gravestones, mortar of houses, stone walls, wooden palings, and such like, the date of whose erection is known. Amongst other instances which have come under the present writer's own observation may be adduced the case of *Physcia purietina*, growing in fair quantity on the stones of a granite wall built in 1836 in a maritime district where the plant is extremely abundant, and where atmospheric and other conditions are well suited for its growth. In a recent visit to the spot it was found that, although the thallus is now well developed, no fructification whatever is visible, though traces of spermatogones are beginning to appear, so that in the space of forty-five years this plant has not yet attained full maturity. But slow as is the growth of lichens after a certain stage of their development, their tenacity of life is very remarkable, as might *a priori* be inferred from their capacity of enduring without injury the greatest extremes of temperature and of hygrometrical conditions. It is on record that, after the lapse of nearly half a century, the same specimen on the same spot of the same tree has been observed without any change in its condition. On this point also E. Fries (in *L. B.*, p. xlv.) notices that certain species such as *Physcia ciliata*, kept in houses for upwards of a year, revive when again exposed to the influences of the atmosphere,—an observation which in the case of *Cladonia rangiferina* similarly kept for a still longer period the present writer can fully corroborate. Endowed then with this singular intermittent vitality, we can easily understand how many individuals which occur on hard mountainous rocks or on the trunks of aged trees in ancient forests are in all probability many hundreds of years old. Nor does age seem in any way to weaken their fecundity, even when the

thallus has apparently ceased to grow. This, as observed by Nylander (in *Syn.*, p. 5), is shown from the circumstance that were it otherwise "the already old fruits would be destitute of spores, which is never the case," unless in plants of some lower tribes, e.g., *Graptolidea* and *Tremacaria*, in which the thallus is but sparingly gonidiose, and the life consequently is shorter. In other instances the central portion of the thallus sometimes normally perishes in old plants, as in *Pterygium centrifugum*, *Colema melanum*, *Parmelia centrifuga*, and *P. saxatilis*, leaving only peripheral circles, in which, however, the life of the individual still continues for ages. In fact, "the life of lichens bears in itself no cause of death, and is only to be ended by external injuries" (E. Fries, *L. B.*, loc. cit.), or by the alteration of climatic and atmospheric conditions. Hence the assumption is not unwarrantable that individuals of such confessedly long-lived species as *Leccidea geographicus*, growing on rocks upon the summits of lofty mountains, date from more than "fabulous epochs," and probably outlive in longevity the ages assigned to the oldest trees on the surface of the globe.

Chemistry of Lichens, and Chemical Reactions.

Chemistry of Lichens.—This is still but little understood, notwithstanding that the subject has been more or less investigated by authors. Their examinations, however, have been too limited and desultory to enable us to give any detailed account of the different principles which enter into the composition of the lichen tissues. Moreover, with respect to those species which have been more particularly analysed, they have sometimes employed not only the same terms in different senses, but also different terms to denote the same substance. There can, however, be no doubt that the chemical composition of lichens not only produces great modifications in their form, but also considerable diversities in their properties.

The principal substance which occurs in lichens, especially in such as are foliaceous and fruticulous, is *lichenin*—a special kind of gelatin peculiar to them. It is intermediate in character between dextrin and starch, and very cogely imbibes water; though if boiled in water it is dissolved and lost. Starch also very rarely occurs in large lichenular grains scattered in the tissues. In crustaceous lichens *oxalate of lime* predominates, and forms a large proportion of the thallus, e.g., 65 per cent. in *Leccidea esculenta* according to Gebel. *Chlorophyll* and its modification *phycochroms* are found in lichens only in relatively small quantities, as is also the case with most of the other principles they present. These are enumerated by Nylander (in *Syn.*, p. 61) according to the affinities they bear, as follows:—(1) phosphate of lime, sea-salt, manganese, iron, (2) picroleucine, varicoline, creosote, cotinine, fauline, erythrine, roselline, picroerythrine; (3) glyphoric acid, paralic acid, umac acid, oxalic acid, erythric acid; (4) sugar not crystallisable, oil, waxy matter, resinous matter. Several others, especially phosphates and acids, have been enumerated by authors, which in some instances have not been corroborated, and in others are doubtfully distinct. In illustration of the manner in which several of these principles enter into the composition of lichens, we may adduce the analyses given in one or two species which have been more fully subjected to experiment. In *Cetraria islandica* there have been detected *emch*, including lichenine and umaline, to the extent of 80 per cent.; gummy and waxy matters; a bitter principle, *cetrarin* acid; a fatty principle, *ichthostearic acid*; *fumaric acid*, which exists also in *Dumortiera officinalis*; *gallic acid*, the astringent principle of galls, uncrystallisable sugar; various salts, such as *bisulphate of potash*, and *carbonate and phosphate of lime*. Again, in *Physcia porietina* there have been found several alimentary principles, as *glutidine*, *starch*, *sugar*, *gum*; several medicinal substances, as *resin*, *bitter matter*, *gallic acid*, and a peculiar etheric oil; a yellow colouring matter called *erythrophoric acid*; also *resin*, *stearine*, and some salts, as *carbonate of lime*. The ash of lichens is said to constitute from 8 to 10 per cent. of their bulk, and consists of various earthy bases, such as potash, soda, lime, magnesia, alumina, silica, manganese, and peroxide of iron, in combination with various acids, such as carbonic, phosphoric, sulphuric, and hydrochloric. The whole subject, however, of the chemistry of lichens requires to be investigated in a more extensive and methodical manner than has hitherto been done either by chemists or

Chemical Reactions in Lichens.—These have reference to the thallus and the apothecia, and in both respects afford valuable assistance in the systematic study of lichens. (a) *Thallus* reactions depend upon the presence in the thallus of certain colourable materials in the form of acids, and are manifested on the application of hydrate of potash and the hypochlorite of lime either on the cortical stratum or the medulla. Of these reagents, hydrate of potash (K), composed of equal weights of caustic potash and water, and hypochlorite of lime (CaCl), composed of chloride of lime and water of any strength, may give certain reactions or none, according to the presence or absence of particular acids in the thallus. If no reaction takes place, this is denoted by K-, CaCl-, and similarly if there is reaction by K+, CaCl+. A very convenient mode of symbolizing the positive and negative reactions of the cortical layer and the medulla of the same species is to place the reaction of the former above the latter, e.g., K⁺, CaCl⁺, denoting that with K the cortical stratum shows reaction and the medulla none, while with CaCl the cortical stratum gives none, but the medulla a distinct reaction. Again, there is often no reaction produced by K alone, but if CaCl be added to it while still moist, a decided reaction appears, for which K(CaCl) is the symbol; or, on the other hand, the reaction given by K may be neutralized by the immediate application of CaCl, in which case it is expressed by K+(CaCl)-. The positive reactions are due to the presence of particular acids in the thallus, such as *erythrone* acid giving a crimson reaction with CaCl, *chrysophanic* acid giving a purple reaction with K, *glauconic* acid giving a yellow reaction with CaCl, and *lecanoric* acid giving a crimson reaction with K. In most cases where the natural colour of the thallus (often also of the medulla) is yellow or orange, chrysophanic acid is present, and with K gives a purple reaction (e.g., *Phycia lychnis*), but in others externally similar in colour and general appearance, where only *leucophanic* acid is present (e.g., *Lecanora leucophaea*), K gives no reaction whatever. Sometimes K produces at first a yellow colour which immediately changes into a red or purple, as in *Lecanora cinerea*, which at once enables us to distinguish it from the closely allied species *L. gibbosa* and *L. calceola*. A solution of iodine (I) is also in certain cases useful as a test on the medulla, and in the discrimination of some species of *Gyrodia*. The value of these chemical tests in lichens was first pointed out by Nylander in *Flora*, 1868, pp. 223, 224, was subsequently illustrated by him in *Flora*, 1869, *passim*, in the case of species belonging to various genera, and has since been generally acknowledged by lichenists and employed by them in all species diagnoses. The reactions are of great importance, not only in the discrimination of many difficult and closely allied species, but also in enabling us to refer with certainty varieties to the species to which they properly belong. Nay, even a small fragment of the thallus, whether sterile or fertile, may by their aid be readily determined. The reactions of most of the quite undecomposable or doubtful. Generally they may be obtained on any portion of the thallus, but they are frequently more vivid, as might be expected, in the growing or circumferential portions. It is, however, only immediate reactions which depend on the colouring matter contained in the cortical stratum and the medulla that are to be attended to, and not secondary or tardy reactions which may otherwise originate, e.g., from the dissolution of the chlorophyll in the gonidia. At the same time it is to be observed, in order to prevent a misconception which has occasionally been entertained, that they do not *per se* constitute a special specific character, but only an additional or corroboratory specific character. As such, their value is clearly apparent in cases where the external characters are similar or approximate, and doubt necessarily exists as to their specific value. (b) *Apothecial* reactions for the most part take place either externally on the epithemum or internally on the hymenial gelatin. The reactions of the epithemum are generally produced by K on species which have yellow or orange apothecia (e.g., *Lecanora aurantiaca*, *Lecidea leucocanthos*), while others with concolorous apothecia (e.g., *Lecanora epomora*, *Lecidea lucida*) give no reaction whatever, owing to the presence or absence of chrysophanic acid. In certain cases also the reaction with CaCl is very useful in enabling us to separate closely allied species with similar apothecia, e.g., *Lecanora subcaneana* (epithemum CaCl-) from *L. glauconia* (epithemum CaCl+yellow). Again, with respect to the reaction of the hymenial gelatin, this, as already observed, depends on the application of a solution of iodine. The formula by which the solution is to be prepared is—iodine, gr. i; volatile of potash, gr. ii; distilled water, a ounce. In most lichens, where the spores are mature, this solution will tinge the hymenial gelatin in some cases only blue, in others at first blue and then wine-red, and in others wine-red or tawny wine-coloured only, without any preceding blue tinge. In such instances the reaction obtained is often very useful as a confirmatory specific character. Sometimes, however, the blue reaction takes place only on the thallus (e.g., *Peridermium*, *Cladonia*, &c.), and at other times only on the epispore (e.g., *Graphis*, *Thelotrema*, &c.). In the case of some species belonging to the inferior genera the reaction with I is especially valuable for the assistance it lends in distinguishing them from certain pyrenomy-

cetous fungi, to which otherwise they might be supposed to belong. True, in some fungi (e.g., *Fusca*) we obtain a reaction with I, and in some lichens we have no reaction visible; but otherwise in such exceptional instances their respective anatomical characters readily show to which class they belong.

Economic Uses of Lichens.

These are intimately connected with their chemical constituents, and are in some respects very important. In the arts, as food and as medicine, many of them have been highly esteemed, though others are not now employed for the same purposes as formerly.

1. *Lichens Used in the Arts*.—Of these the most important are such as yield, by maceration in ammonia, the valuable dyes known in commerce as archil, cudbear, and litmus. These, however, may with propriety be regarded as but different names for the same pigimentary substance, the variations in the character of which are attributable to the different modes in which the pigments are manufactured. Archil proper is derived from several species of *Rocella* (e.g., *R. Montagnei*, *R. tinctoria*), which yield a rich purple dye and fetch a high price in the market. Of considerable value is the "perilla" prepared from *Lecanora parella*, and much used in the preparation of a red or crimson dye. Inferior to this is "cudbear," derived from *Lecanora tartarea*, which was formerly very extensively employed by the peasantry of north Europe for giving a scarlet or purple colour to woollen cloths. By adding certain alkalis to the other ingredients used in the preparation of these pigments, the colour becomes indigo-blue, in which case it is the litmus of the Dutch manufacturers. Amongst other lichens affording red, purple, or brown dyes may be mentioned *Ramalina scopulorum*, *Parmelia saxatilis* and *P. omphalodes*, *Umilicaria pustulata* and several species of *Gyrophora*, *Urcularia cerporea*, all of which are more or less employed as domestic dyes. Yellow dyes, again, are derived from *Cladonia vulpina*, *Platysma juniperinum*, *Parmelia asperata* and *P. conspersa*, *Phycia flavicans*, *Ph. parietina*, and *Ph. lychnis*, though like the preceding they do not form articles of commerce, being merely used locally by the natives of the regions in which they occur most plentifully. In addition to these, many exotic lichens, belonging especially to *Parmelia* and *Sticta* (e.g., *Parmelia tinctorum*, *Sticta argyraea*), are rich in colorific matter, and, if obtained in sufficient quantity, would yield a dye in every way equal to archil. These pigments primarily depend upon special acids contained in the thalli of lichens, and their presence may readily be detected by means of the reagents already noticed. In the process of manufacture, however, they undergo various changes, of which the chemistry is still but little understood. At one time also some species were used in the arts for supplying a gum as a substitute for gum-arabic. These were chiefly *Ramalina fraxinea*, *Evernia prunastri*, and *Parmelia physodes*, all of which contain a considerable proportion of gummy matter (of a much inferior quality, however, to gum-arabic), and were employed in the process of calico-printing and in the making of parchment and cardboard. In the 17th century some filamentous and fruticulous lichens, viz., species of *Ulex* and *Ramalina*, also *Evernia furfuracea* and *Cladonia rangiferina*, were used in the art of perfumery. From their supposed aptitude to imbibe and retain odours, their powder was the basis of various perfumes, such as the celebrated "Poudre de Cypre" of the hairdressers, but their employment in this respect has long since been abandoned.

2. *Nutritive Lichens*.—Of still greater importance is the capacity of many species for supplying food for man and beast. This results from their containing amylaceous substances, and in some cases a small quantity of saccharine

matter of the nature of mannite. One of the most useful nutritious species is *Cetraria islandica*, "Iceland moss," which, after being deprived of its bitterness by boiling in water, is reduced to a powder and made into cakes, or is boiled and eaten with milk by the poor Icelandic, whose sole food it often constitutes. Similarly *Cladonia rangiferina* and *Cl. sylvatica*, the familiar "reindeer moss," are frequently eaten by man in times of scarcity, after being powdered and mixed with flour. Their chief importance, however, is that in Lapland and other northern countries they supply the winter food of the reindeer and other animals, who scrape away the snow and eagerly feed upon them. Another nutritious lichen is the "Tripe de Roche" of the Arctic regions, consisting of several species of the *Gyrophoraceae*, which when boiled is often eaten by the Canadian hunters and Red Indians when pressed by hunger. But the most singular esculent lichen of all is the "mannia lichen," which in times of drought and famine has served as food for large numbers of men and cattle in the arid steppes of various countries stretching from Algiers to Tartary. This is derived chiefly from *Leconora esculenta*, which grows unattached on the ground in layers from 3 to 6 inches thick over large tracts of country in the form of small irregular lumps of a greyish or white colour. Speaking of the distribution of these nutritive lichens, whose qualities depend on the presence of amylaceous matter, Dr. Lindsay (in *Pop. Hist. Brit. Lich.*, p. 82) very appropriately remarks that, "by a beautiful provision of nature, they occur precisely under the circumstances where they are most wanted—in northern or arctic countries, or on arid steppes, where grain stuffs are unknown, and food of a better kind is often scarce or deficient." In connexion with their use as food we may observe that of recent years in Scandinavia and Russia an alcoholic spirit has been distilled from *Cladonia rangiferina* and extensively consumed, especially in seasons when potatoes were scarce and dear. Formerly also *Stictia pulmonaria* was much employed in brewing instead of hops, and it is said that a Siberian monastery was much celebrated for its beer which was flavoured with the bitter principle of this species.

3. *Medicinal Lichens*.—During the Middle Ages, and even in some quarters to a much later period, lichens were extensively used in medicine in various European countries. Many species had a great repute as demulcents, febrifuges, astringents, tonics, purgatives, and anthelmintics. The chief of those employed for one or other, and in some cases for several, of these purposes were *Cladonia pyxidata*, *Ulex barbata*, *Ramalina farinacea*, *Evernia prunastri*, *Cetraria islandica*, *Stictia pulmonaria*, *Parmelia saxatilis*, *Physcia parietina*, and *Pertusaria amara*. Others again were believed to be endowed with specific virtues, e.g., *Peltigera canina*, which formed the basis of the celebrated "pulvis antilyssus" of Dr. Mead, long regarded as a sovereign cure for hydrophobia; *Platyma juniperinum*, lauded as a specific in jaundice, no doubt on the *antilia emulibus* principle from a resemblance between its yellow colour and that of the jaundiced skin; *Peltidea aphthosa*, which on the same principle was regarded by the Swedes, when boiled in milk, as an effectual remedy for the *aphthae* or rash on their children. Almost all of these virtues, general or specific, were imaginary; and at the present day, except perhaps in some remote districts of northern Europe, only one of them is employed as a remedial agent. This is the "Iceland moss" of the druggists' shops, which is undoubtedly an excellent demulcent in various dyspeptic and chest complaints. Probably also *Pertusaria amara*, from the intensely bitter principle which it contains, might still with propriety be employed as a febrifuge. No lichen is known to be possessed of any poisonous properties, although *Chlorea pulvinata* is believed by the Swedes to be

destructive to wolves when powdered and "mixed with pounded glass." Nor are lichens, as has sometimes been alleged, injurious to the trees upon which they grow, except to a very limited extent. Not being parasites properly so called, the only injury they can inflict upon them is by slightly interfering with the functions of respiration, or, when growing very crowdedly upon the branches of orchard trees, by checking the development of buds.

Classification of Lichens.

From the time of Acharius, the father of lichenological science, different authors have proposed different classifications of lichens, according to the degree of importance attached by them to one or other of their vegetative and reproductive organs. Most of these classifications, however, whether proposed by microscopical or pre-microscopical lichenists, have been too artificial and arbitrary, and indeed less natural in various ways than that originally propounded by Acharius. Of recent years they have been entirely superseded by other two systems, viz., that of the Massalongo-Koerberian and that of the Nylanderian school. With respect to the former of these, its characteristic feature is the prominence which it assigns to the form and structure of the spores not only in the differentiation of species but also in the foundation of genera. Though it has been adopted, with various modifications, by many Continental lichenists, yet essentially it also proceeds on an artificial principle, and necessitates the adoption of far too many genera, distinguished from each other merely by slight differences in the spores. The other system—that of Nylander, which was first proposed by him in his *Essai d'une Nouvelle Classification des Lichens* (1854-55),—has since then commended itself more and more to the acceptance of lichenists, so that even the disciples of the opposite school (the sporologists) have in many respects gradually approximated towards it in their most recent writings. Not only is it the only complete system of classification yet wrought out; it is also the most natural and philosophical of any hitherto propounded. In its main outline it proceeds upon the principle of showing the near relation of certain lichens to some genera of algae on the one hand, and of certain other lichens to some genera of fungi on the other hand, and connects these three great classes of cryptogams together by a sort of twofold chain, commencing with those genera of lichens nearest allied to the algae, working up to those genera best developed (*Stictia*), and thence retrograding and terminating with those nearest allied to the fungi. His genera also are principally founded, not upon a single special character, but upon the combined anatomical characters presented by the thallus, the apothecia, and the spores. It may here be further observed that we are indebted to the same accomplished lichenist for the succinct but comprehensive diagnoses, generic and specific, of the different parts of a lichen, which have tended so much to facilitate their systematic study. The following is a synopsis of the Nylanderian classification of lichens, with the leading characters of the different families and tribes, and an enumeration of all the principal genera of which these are composed.

Family I.—*Sphaerocetæ*, Nyl.

Thallus but little turgid when moist, gonidial stratum consisting of gonimia which are tumidate; medullary filaments none.

Tribe 1. *Sphaerophenæ*, Nyl.—Thallus filamentoso-fruticulosus, gonimia vacuolately connate. Apothecia basiform or lecidiform. Spores gonimata or sphaerostigmata.

Genera: *Sphaerophora*, Ktze.; *Goniomeria*, Nyl.; *Sphaeromeria*, Born. Tribe 2. *Pyrenopezizæ*, Nyl.—Thallus thinly granulose, rubraceous within, gonimia simple or connate. Apothecia lecanioid or pyrenopezizoid. *Sphaeromeria* with striatulate apothecia.

Genera *Eusporia*, Nyl.; *Pyrenopeziza*, Nyl.

Tribe 3 *Homonidacea*, Nyl.—Thallus either fruticose with the gonimia sessile, or squamuliform or granulose with the gonimia subulterior. Apothecia pyrenopezizoid with or without paraphyses. Sporegonia with simple sterigmata.

Genera *Epiclita*, Fr.; *Epiclita*, Nyl.; *Phyllostictum*, Nyl.; *Collemopodium*, Nyl.

Tribe 4 *Magnopora*, Nyl.—Thallus pyrenopezizoid, containing syngonimia, the gonimia arranged without order. Apothecia petiolate.

Genera *Magnopora*, Nyl.

Family II — *Collema*, Nyl

Thallus tergal when moist, gonidial stratum consisting of gonimia uniformly arranged, medulla not discrete.

Tribe 1 *Lichina*, Nyl.—Thallus fruticose or radially lacinated, gonimia elongato-sessile moniliform, subconnate. Apothecia lecanorine or lecanine. Sporegonia with sterigmata or arthrosterigmata.

Genera *Lichina*, Ag.; *Pterygium*, Nyl.; *Leptogium*, Nyl.; *Lichinidium*, Nyl.

Tribe 2 *Collema*, Nyl.—Thallus membranaceous, lobate, rarely fruticose, granulose or subequamuliform, gonimia moniliformly arranged, cortical stratum none or distinct. Apothecia lecanorine or rarely pyrenopezizoid. Sporegonia with simple sterigmata or arthrosterigmata.

Genera *Leptophyllum*, Fr. fil.; *Synalasia*, DR.; *Omphalium*, DR.; *Aeneia*, Nyl.; *Paulia*, Fée.; *Schizoma*, Nyl.; *Collema*, Ach.; *Leptogium*, Ach.; *Zamacladonia*, Nyl.; *Lichinella*, Nyl.; *Ampodium*, Nyl.; *Collema*, Nyl.; *Egyrotrichum*, Russ.

Tribe 3 *Epyridicta*, Nyl.—Thallus fibrillose, gonimia moniliformly coherent, cortical stratum distinct. Apothecia pyrenopezizoid.

Genera *Epyridicta*, Nyl.

Family III — *Lichenaria*, Nyl.

Thallus not gelatinous, with a gonidial, rarely gonimic stratum, medullary stratum more or less distinct.

Series I — *Eponidicta*, Nyl

Apothecia with the apices usually naked and pulverulent on the surface of the fructification.

Tribe 1 *Calicia*, Nyl.—Thallus horizontally expanded, sometimes none. Apothecia stipitate, capsuliform or sessile. Sporegonia with simple sterigmata.

Genera *Sphinctrina*, Fr.; *Calicia*, Pers.; *Stenocleia*, Nyl.; *Conocarpus*, Ach.; *Epyridicta*, Nyl.; *Trachylia*, Fr.; *Pyrulium*, Nyl.

Tribe 2 *Tylophora*, Nyl.—Thallus thinly crustaceous. Apothecia at first pyrenopezizoid and then lecanorine with sporal mass. Sporegonia with somewhat branched sterigmata.

Genera *Tylophora*, Nyl.

Tribe 3 *Sphaerophora*, Nyl.—Thallus fruticose, branched. Apothecia at first nucleiform, becoming variously dehiscence, with sporal mass. Sporegonia with simple sterigmata or arthrosterigmata.

Genera *Sphaerophora*, Pers.; *Acrocephalus*, Lev.; *Tholurus*, Norm.

Series II. — *Cladodes*, Nyl

Apothecia terminal on podetia, rarely sessile, batorine or rarely lecanorine.

Tribe 4 *Bromyelidicta*, Nyl.—Thallus horizontally expanded. Apothecia substipitate. Sporegonia with sterigmata or arthrosterigmata.

Genera *Gomphallium*, Nyl.; *Bromyces*, Pers.; *Glossidium*, Nyl.; *Thylenachium*, Berk.; *Stereocaulium*, Nyl.

Tribe 5 *Pidalia*, Nyl.—Thallus granulose, cephalodiferous, with rigid podetia. Apothecia cephalodine on the podetia, with the paraphyses prolonged into the hypothecium. Sporegonia with simple sterigmata.

Genera *Pidalia*, Nyl.

Tribe 6 *Stereocaulium*, Nyl.—Thallus cespitose, podetiform, solid. Apothecia terminal or lateral, lecanine or rarely lecanorine. Sporegonia with simple sterigmata.

Genera *Stereocaulium*, Schreb.; *Stereocaulium*, Nyl.; *Aigopsis*, Fr. fil.; *Ovalidium*, Mnt.

Tribe 7 *Cladonia*, Nyl.—Thallus folioseous or fruticose, with fissure podetia. Apothecia biatorine on the podetia, rarely sessile on the leaflets. Sporegonia with simple sterigmata.

Genera *Heterodermis*, Nyl.; *Pycnothelia*, Ach.; *Cladonia*, Hoffm.; *Cladonia*, Nyl.; *Cladonia*, Nyl.; *Ramalina*, Nyl.

Series III. — *Ramalina*, Nyl

Thallus folioseous, fruticose, or filamentous. Apothecia generally lecanorine.

Tribe 8 *Rocella*, Nyl.—Thallus simple or branched, internally with filamentous medulla. Apothecia irregular (normally lecanorine), adnate, terminal, or lateral. Sporegonia with simple sterigmata.

Genera *Rocella*, DN.; *Rocella*, DC.

Tribe 9 *Siphuleti*, Nyl.—Thallus podetiform, simple or fruticose, internally with filamentous or stictic medulla. Apothecia unknown. Sporegonia (where seen) with arthrosterigmata.

Genera *Siphuleti*, Fr.; *Endoclea*, Cromb.; *Thamnochrysa*, Ach.

Tribe 10 *Ramalina*, Nyl.—Thallus fruticose-folioseous, rounded or compressed, with woody medulla. Apothecia lecanorine, scutellate. Sporegonia with arthrosterigmata.

Genera *Ramalina*, Ach.

Tribe 11 *Usoeri*, Nyl.—Thallus much branched, rounded, or compressed, with firm medullary axis. Apothecia peltoid, petiolate. Sporegonia with simple sterigmata.

Genera *Usoeri*, Hoffm.; *Neurospora*, N. and Fr.; *Chlorea*, Nyl.

Tribe 12 *Actocera*, Nyl.—Thallus branched, rounded, or compressed, with woody medulla. Apothecia peltoid, scutelliform. Sporegonia with simple sterigmata or arthrosterigmata.

Genera *Actocera*, Ach.; *Actocera*, Nyl.; *Dufourea*, Ach.

Tribe 13 *Cetraria*, Nyl.—Thallus fruticose or folioseous, with woody medulla. Apothecia peltoid, marginal, obliquely affixed. Sporegonia with simple sterigmata or arthrosterigmata.

Genera *Cetraria*, Ach.; *Platyura*, Hoffm.

Series IV. — *Phylloidea*, Nyl

Thallus folioseous, usually depressed, lobate. Apothecia generally peltiform or lecanorine.

Tribe 14 *Parmitia*, Nyl.—Thallus frondosely dilated, or lobate, or lacinated, with woody, rarely solid, medulla. Apothecia peltoid, scutelliform. Sporegonia with simple sterigmata or arthrosterigmata.

Genera *Parmitia*, Ach.; *Evernia*, Nyl.; *Parmitia*, Ach.; *Parmitia*, Nyl.

Tribe 15 *Stictis*, Nyl.—Thallus large, lobate, cyphellate, or cyphellate beneath, gonidial stratum composed either of nodulose gonimia or of true gonidia. Apothecia lecanorine, rarely perithecioid. Sporegonia with arthrosterigmata.

Genera *Stictis*, Nyl.; *Lecanaria*, Nyl.; *Stictis*, Ach.; *Lecanaria*, Nyl.; *Stictis*, DN.

Tribe 16 *Peltigera*, Nyl.—Thallus frondosely dilated, the cortical stratum often wanting beneath, gonidial stratum consisting either of gonidia or (usually) of gonimia, rarely of gonidia. Apothecia peltiform, adnate, or innate. Sporegonia (where seen) with arthrosterigmata.

Genera *Nephroma*, Ach.; *Nephroma*, Nyl.; *Peltigera*, Ach.; *Peltigera*, Hoffm.; *Solitaria*, Ach.

Tribe 17 *Physcia*, Nyl.—Thallus stellato-obovate, rarely fruticose, internally with woody medulla. Gonidial stratum consisting of true gonidia. Apothecia lecanorine. Sporegonia with arthrosterigmata.

Genera *Physcia*, Nyl.

Tribe 18 *Punctelia*, Nyl.—Thallus stellato-laciniate, with woody medulla and true gonidial stratum. Apothecia lecanorine. Sporegonia with arthrosterigmata.

Genera *Punctelia*, Fr.

Tribe 19 *Gyrophora*, Nyl.—Thallus umbilicately affixed, with woody medulla and true gonidial stratum. Apothecia lecanorine, or lecanine and gynoecious. Sporegonia with arthrosterigmata.

Genera *Umbilicaria*, Hoffm.; *Gyrophora*, Ach.

Series V. — *Placodi*, Nyl

Thallus variously crustaceous, sometimes evanescent, rarely hypophloeoid, without any filamentous medullary stratum. Apothecia lecanorine, or lecanine, or imbricate.

Tribe 20 *Lecanora*, Nyl.—Thallus crustaceous, rarely evanescent or obsolete. Gonidial stratum consisting of gonidia, rarely of gonimia. Apothecia lecanorine, rarely subulterior or typically biatorine. Sporegonia with simple sterigmata or arthrosterigmata.

Genera *Pannaria*, Del.; *Gynodermis*, Nyl.; *Brodiaea*, Fée.; *Hippia*, Neg.; *Amphileta*, Fr.; *Pannaria*, Fr.; *Lecanora*, Ach.; *Ophiodermis*, Nyl.; *Peltula*, Nyl.; *Dermatium*, Nyl.; *Dermis*, Fr.

Tribe 21 *Pertusaria*, Nyl.—Thallus crustaceous, continuous, gonidial stratum consisting of true gonidia. Apothecia endocarpioid or lecanorine. Sporegonia with simple sterigmata.

Genera *Pertusaria*, DC.; *Pertusaria*, Nyl.

Tribe 22 *Thelotrema*, Nyl.—Thallus crustaceous, or pulverulent, or areolate, with true gonidial stratum. Apothecia urceolot-impregnated with double margin. Sporegonia with simple or somewhat branched sterigmata.

Genera *Thelotrema*, Wallr.; *Tremotium*, Nyl.; *Thelotrema*, Ach.; *Thelotrema*, Ach.; *Thelotrema*, Fr.; *Thelotrema*, Nyl.; *Acidulum*, Fée.; *Gynodermis*, Nyl.

Tribe 23 *Lecidea*, Nyl.—Thallus variously crustaceous, pulverulent, evanescent or none proper, with the gonidial stratum consisting of gonidia (rarely obryogonidia), rarely gonimia. Apothecia lecanine (or basiconic). Sporegonia with simple or simple sterigmata.

Genera *Canthopeltis*, Ehrh.; *Byssoecium*, Mnt.; *Pannaria*, Nyl.; *Conocarpus*, Pers.; *Lecidea*, Ach.; *Gyrodactylum*, Nyl.; *Epithemia*, Nyl.

Tribe 24. *Graphidea*, Nyl.—Thallus thinly crustaceous, or hypophloeoid, or rarely none proper; gonial stratum consisting of gonimia (rarely diacygonimia). Apothecia hirsute or reticulate. Spermogones with simple sterigmata.

Genera. *Xylographa*, Fr., *Aggraria*, Fr.; *Lithographa*, Nyl.; *Graphis*, Ach.; *Thelographis*, Nyl.; *Melminthocarpa*, Fée; *Lecanographa*, Nyl.; *Opographis*, Ach.; *Platygrapha*, Nyl.; *Stigmatidaceae*, Mey.; *Albidaria*, Ach.; *Melanogonia*, Nyl.; *Lecanactis*, Eschsch.; *Schizoglyphis*, Nyl.; *Glyptis*, Ach.; *Chiodacton*, Ach.

Series VI.—*Pyrenoclii*, Nyl.

Thallus peltoide, or crustaceous, or hypophloeoid, or evanescent. Apothecia imbriciform, with an apical umbel.

Tribe 25. *Pyrenocarpi*, Nyl.—Thallus various, often macular or olivolete, gonial system consisting of gonimia (rarely diacygonimia), sometimes of gonimia. Apothecia pyrenoidiform, often without paraphyses. Spermogones with simple sterigmata or atrostostigmata.

Genera. *Cora*, Fr.; *Endocarpus*, N. ab Es.; *Von-mundia*, Nyl.; *Endocarpus*, Helw.; *Pyrenocarpus*, Nyl.; *Verrucaria*, Pers.; *Thelocelia*, Nyl.; *Thelopsis*, Nyl.; *Orizans*, Wallr.; *Strigula*, Fr.; *Parathecium*, Nyl.; *Melanotheca*, Fée; *Tryptothelium*, Ach.; *Astrothelium*, Eschsch.

Series VII.—*Psilidioides*, Nyl.

Thallus thin, often wanting. Apothecia peridiciform, without any ostiole.

Tribe 26. *Psilidi*, Nyl.—Thallus thin, macular, or none proper. Apothecia consisting of a peridium. Spermogones (where seen) with simple sterigmata.

Genera. *Thelocarpus*, Nyl.; *Spelocarpus*, Nyl.; *Endocarpus*, Nyl.; *Myocarpus*, Flot.

Family IV.—*Mysrangaceae*, Nyl.

Thallus unstratified, entirely and equally cellulosic. Fructification not discrete.

Tribe 1. *Mysrangia*, Nyl.—Thallus noduloso-pulvinat. Apothecia subconiciform. Spermogones unknown.

Genus. *Mysrangium*, Mnt and Berk.

In the *Mysrangium* arrangement, most of these tribes and genera are again divided into subtribes and subgenera, the latter being further subdivided into sections according to the affinities of the different species.

Habits and Distribution of Lichens.

These two subjects are intimately related and present many interesting features which here we can only very generally notice without entering into details.

1. *Habits of Lichens*.—These are extremely varied, and comprehend a great number of very different substrata. Chiefly, however, they are the bark of trees, rocks, the ground, mosses, and, rarely, perennial leaves. (a) With respect to corticole lichens, some prefer the rugged bark of old trees (e.g., *Ramalina*, *Parmelia*, *Stictis*), and others the smooth bark of young trees and shrubs (e.g., *Graphidea* and some *Lecidea*). Many are found principally in large forests (e.g., *Usnea*, *Alectoria jubata*); while a few occur more especially on trees by roadsides (e.g., *Physcia parietalis* and *Ph. pulverulenta*). In connexion with corticole lichens may be mentioned those lignicole species which grow on decayed or decaying wood of trees and on old pales (e.g., *Calicidia*, various *Lecidea*, *Xylographa*). (b) As to saxicole lichens, which occur on rocks and stones, they may be divided into two sections, viz., calcicole and calcifugus. To the former belong such as are found on calcareous and cretaceous rocks, and the mortar of walls (e.g., *Lecanora calcarea*, *Lecidea calcivora*, and several *Verrucaria*), while all other saxicole lichens may be regarded as belonging to the latter, whatever may be the mineralogical character of the substratum. It is here worthy of notice that the apothecia of several calcicole lichens (e.g., *Lecanora Prevostii*, *Lecidea calcivora*) have the power (through the carbonic acid received from the atmosphere) of forming minute favelli in the rock, in which they are partially buried. (c) With respect to terricole species, some prefer peaty soil (e.g., *Cladonia*, *Lecidea decolorata*), others calcareous soil (e.g., *Lecanora crassa*, *Lecidea decipiens*), others argillaceous soil or hardened mud (e.g., *Colema limosum*, *Peltidea venosa*); while many may be found growing on all kinds of soil,

from the sands of the sea-shore to the granitic detritus of lofty mountains, with the exception of course of cultivated ground, there being no agrarian lichens. (d) *Muscolae* lichens again are such as are most frequently met with on decayed mosses and jungermannias, whether on the ground, trees, or rocks (e.g., *Lepidogium muscicola*, *Gomphillus calcivivida*). (e) The epiphyllous species are very peculiar as occurring upon perennial leaves of certain trees and shrubs, whose vitality is not at all affected by their presence as it is by that of fungi. In so far, however, as is known, they are very limited in number (e.g., *Lecidea Bouteilleri*, *Strigula*). With the exceptions of these last, it is to be observed that all the rest may, under different conditions of locality and climate, be found growing for the most part indiscriminately on the substrata mentioned, a normally saxicole species becoming corticole, a terricole one becoming muscicola, and vice versa. Amongst other instances of this that might be adduced, the case of *Lecidea geographica*, a peculiarly saxicole species, growing on the stems of *Rhododendron* in the Tyrolean Alps, and that of *Lecidea rivulosa*, a like peculiarly saxicole species, growing on the bark of trees in Germany, are especially striking. Sometimes also various lichens occur abnormally in such unexpected habitats as dried dung of sheep, bleached bones of reindeer and whales, old leather, iron, and glass, in districts where the species are abundant. Consequently it is apparent that in many cases lichens are quite indifferent to the substrata on which they occur, whence we infer that the preference of several for certain substrata depends upon the temperature of the locality or that of the special habitat. Thus in the case of saxicole lichens the mineralogical character of the rock has of itself little or no influence upon lichen growth, which is influenced more especially and directly by their physical properties, such as their aptitude for imbibing and retaining heat and moisture. As a rule lichens have a propensity for open exposed habitats, though some are found only or chiefly in shady situations; while, as already observed, scarcely any occur where the atmosphere is impregnated with smoke. Many species also prefer growing in moist places by streams, lakes, and the sea, though very few are normally, and probably none entirely, aquatic, being always at certain seasons exposed for a longer or shorter period to the atmosphere (e.g., *Lichina*, *Leptogium rivulare*, *Endocarpus fumatilis*, *Verrucaria maura*). Some species are entirely parasitical on other lichens (e.g., various *Lecidea* and *Pyrenocarpi*), and may be peculiar to one (e.g., *Lecidea niellinaria*) or common to several species (e.g., *Habrothallus parietinarum*). A few, generally known as *erratic* species, have been met with growing unattached to any substratum (e.g., *Parmelia revoluta*, var. *concentrica*, *Lecanora esculenta*); but it seems somewhat doubtful if these are really free *ab initio* (vide Crombie in *Journ. Bot.*, 1873, p. 306). It is to the different characters of the stations they occupy with respect to exposure, moisture, &c., that the variability observed in many types of lichens is to be attributed. The fact also that in numerous instances they are so indifferent to the nature of their habitats clearly shows that they do not at all depend upon the substratum for their nourishment.

2. *Distribution of Lichens*.—From what has now been said it will readily be inferred that the distribution of lichens over the surface of the globe is regulated, not only by the presence of suitable substrata, but also and more especially by atmospheric and climatal conditions. At the same time it may safely be affirmed that their geographical range is more extended than that of any other class of plants, occurring as they do in the coldest and warmest regions—on the dreary shores of the paleocretic sea and in the torrid valleys of tropical climes, as well as on

the greatest mountain elevations yet attained by man, on projecting rocks even far above the snow-line (e.g., *Lecidea geographica*), where, as in many other situations, fungus-mycelium and gonoid algal are unknown. Our knowledge of the distribution of lichens in various countries, like that of other plants, is derived from general and local floras, from special works on lichenology, from the observations of scientific travellers and the collections made by them in distant parts of the world. Most of these, however, of an earlier date, are to be used with great caution, as the species recorded were, in the absence of microscopical examination, not sufficiently discriminated, and in many cases are *prima facie* entirely erroneous. Amongst botanical travellers whose contributions are most trustworthy may be mentioned pre-eminently Sir Joseph D. Hooker, whose remarks on this subject in his *Flora Antarctica* and in various papers in *Trans. Linn. Soc.*, vol. xiv, &c., are most valuable and suggestive. Again, in purely lichenological works, the general principles regulating lichen distribution (with statistical tables) are admirably expounded by Nylander in the introduction to his *Synopsis Methodica Lichenum*, while the only complete record of the distribution of species is that given by the same author in his *Énumération générale des Lichens*. Since the date of this latter work (1858) our knowledge of the range of lichens, both European and exotic, has been greatly extended, apart from the discovery of numerous species previously unknown. No special treatise, however, on the subject has been published, though there is now ample material, very much scattered no doubt, available for the purpose. It may, however, be observed that of the four thousand species (exclusive of numerous varieties and forms) which have been described, the geographical distribution is known almost as well as that of phanerogams and filices, as well, if not more so than that of mosses and hepatics, far better than that of algae and fungi. In arctic regions lichens form by far the largest portion of the vegetation, occurring everywhere on the ground and on rocks, and fruiting freely; while teriolic species of *Cladonia* and *Stereocaulon* are seen in the greatest luxuriance and abundance spreading over extensive tracts almost to the entire exclusion of other vegetation. The lichen flora of temperate regions again is essentially distinguished from the preceding by the frequency of corticose species belonging to *Lecanora*, *Lecidea*, and *Graphidæ*. In inter-tropical regions lichens attain their maximum development (and beauty) in the foliaceous *Stictis* and *Parmelites*, while they are especially characterized by epiphyllous species, as *Strigula*, and by many peculiar corticose *Thelotrema*, *Graphidæ*, and *Pyrenopeziza*. Some lichens, especially saxicolous ones, seem to be cosmopolitan (e.g., *Lecanora subfusa*, *Cladonia pyxidata*); and others, not strictly cosmopolitan, have been observed in regions widely apart. A considerable number of species, European and exotic, seem to be endemic, but further research will no doubt show that most of them occur in other climatal regions similar to those in which they have hitherto alone been detected. To give any detailed account, however, of the distribution of the different genera (not to speak of that of individual species) of lichens would necessarily far exceed the limits at our disposal. Suffice it to say that both in horizontal and vertical range, they sufficiently correspond with the distribution of phanerogams in the several regions of vegetation into which the surface of the globe has been divided. The proportion of lichens to phanerogams in different regions increases in a regular ratio from the equator to the poles, and from the base to the summit of lofty mountains, till at length in more arctic and alpine tracts lichens constitute almost and sometimes entirely the sole vegetation. (x. m. c.)

LICHFIELD, a city and municipal and parliamentary borough of Staffordshire, England, is situated in a pleasant and fertile valley, on a small tributary of the Trent, and on the South Staffordshire Railway, 16 miles north from Birmingham. The town is well built, and contains many handsome houses. Of the old Norman cathedral there are now no remains. The present building is supposed to belong to the end of the 12th or beginning of the 13th century. Its style is Early English approaching to Decorated, and it possesses an imposing central tower 385 feet in height, with two western spires 183 feet. The transepts, which contain some portions of Norman architecture, are richly ornamented, and adorned with windows of beautiful tracery. The total length of the building from east to west is 403 feet. The damage which it suffered during the civil wars was repaired by Bishop Hackett in 1671, and at present (1882) it is undergoing extensive restorations. A new building for the King Edward's grammar school was erected in 1860. In the market-place is a statue of Dr Johnson, facing the house where he was born. A guild-hall, a market-hall, a corn exchange, and a public library and museum are the principal buildings of a secular character. There are several charitable institutions. The industries of the town include brewing and coach-building; and in the neighbourhood there are large nurseries and market gardens. The municipal and parliamentary boroughs have the same area (3116 acres); the population in 1871 was 7347, and in 1881 8380.

Lichfield is spelt by Bede Liefeld, the word being supposed to mean "Field of the Dead," from a massacre which took place near it of a large number of Christians. It was made an episcopal see in 692, St Chad being its first bishop. In the reign of Offa it was promoted to be an archbishopric, but in 803 the primacy was restored to Canterbury. In 1075 the see of Lichfield was transferred to Chester, and thence, a few years afterwards, to Coventry, but it was restored in 1148. The town has returned members to parliament since 1805, at which time it also received a charter of incorporation. Since 1667 it has returned only one member. It was made a city by Edward VI. in 1649.

See the histories of Lichfield by Jackson (1805) and Harwood (1806), and histories of the cathedral by Britton (1820) and Stone (1870).

LICHTENBERG, formerly a small German principality on the west bank of the Rhine, enclosed by the Nahe, the Blies, and the Glan, now forms the circle of St Wendel in the government district of Treves, Rhenish Prussia. The principality was constructed of parts of the old electorate of Treves, Pfalz-Zweibrücken, and Salm, and lay between Rhenish Bavaria and the old Prussian province of the Rhine. Originally called the lordship of Baumholder, it owed the name of Lichtenberg and its elevation to a principality to Ernest, duke of Saxe-Coburg, to whom it was presented by Prussia in 1815 in accordance with terms agreed upon at the congress of Vienna. The duke, however, restored it to Prussia in 1834, in return for an annual pension of £26,000 sterling. The area is 210 square miles, and the population 45,000.

LICHTENBERG, GEORG CHRISTOPH (1744-1799), physicist and satirical writer, was born at Oberamstadt, near Darmstadt, July 1, 1744. In 1763 he entered Göttingen university, where in 1770, after spending several years in England, he became extraordinary professor of physics, and five years later ordinary professor. This post he continued to hold till his death, February 24, 1799. As a physicist he is best known for his investigations in electricity, more especially as to the so-called Lichtenberg figures (see vol. viii. p. 66), which are fully described in two memoirs *De nova methodo naturam ac motum fluidi electrici investigandi* (Göttingen, 1778-79). He sent many excellent contributions to the *Göttingen Taschenrechner* from 1778 onwards, and to the *Göttingische Magazin der Literatur und Wissenschaft*, which he edited for three years (1780-82) along with J. G. A. Forster.

His various scientific writings occupy the latter part of his *Vermaelte Schriften*, edited by Kriess (9 vols., Göttingen, 1800–5, new edition, 6 vols., Götting, 1841–46). The earlier volumes of these collected writings contain his satirical and humorous productions. His keen satire involved him in many a literary controversy with well-known contemporaries, such as Lavater, whose science of physiognomy he wittily ridiculed, and Voss, whose views on Greek pronunciation called forth a powerful satire *Ueber die Pronunciation der Schöpfung des alten Griechenlandes* (1782). Notes of his lectures on natural philosophy, astronomy, and physical geography were published by Gamauf (Vienna, 1809–12, 1813, 1819); and more recently some of his brilliant sayings have been collected by Gisebach in one volume, *Lichtenberg's Gedanken und Aeußeren Licht-Strahlen aus seinen Werken* (Leipzig, 1871).

LICINIUS. Publius Flavius Galerius Valerius Licinianus Licinius, Roman emperor, of Dacian peasant origin, was born probably about 250 A.D., and was elevated after the death of Severus to the rank of Augustus by Galerius, his former friend and companion in arms, on November 11, 307, receiving as his immediate command the provinces of Illyrium. On the death of Galerius in May 311, he shared the entire empire with Maximin, the Hellaspont and the Thracian Bosphorus being their mutual boundary. In March 313 he entered into alliance with Constantine at Milan, and in the following month inflicted a decisive defeat on Maximin at Heraclea, with the result of establishing himself as master of the East, while Constantine (now his brother-in-law) was supreme in the West. In the following year his jealousy led him to encourage a treasonable enterprise on the part of Bassianus against Constantine. When his perfidy became known a civil war ensued, in which he was twice severely defeated—first near Cibalis in Pannonia (October 8, 314), and next in the plain of Marica in Thracia, the outward reconciliation, which was effected in the following December, left Licinius in possession of Thracia, Asia Minor, Syria, and Egypt, but added numerous provinces to the Western empire. In 323 Constantine, tempted by the “advanced age and unpopular vices” of his colleague, anew declared war against him, and, having defeated his army at Adrianople (July 3, 323), succeeded in shutting him up within the walls of Byzantium. The defeat of the superior fleet of Licinius by Crispus, Constantine's eldest son, compelled his withdrawal to Bithynia, where a last stand was made, the battle of Chrysopolis (September 18) finally issued in his submission and death.

LIEBER, FRANCIS (1800–1872), a distinguished publicist and writer on political science, was by birth a German, by adoption a citizen of the United States. He was the son of Frederick Wilhelm Lieber, and was born at Berlin, March 18, 1800. Upon the return of Napoleon Bonaparte from Elba, young Lieber, then only fifteen years of age, volunteered as a soldier, and served with his two brothers under Marshal Blücher in the campaign of 1815. He fought at Ligny, Waterloo, and Namur. In the last-named battle he was twice severely and dangerously wounded. At the close of the war he returned to his studies, and joined the Berlin gymnasium under Dr. Jahn. Shortly afterwards he was arrested and thrown into prison for his political sentiments, the chief evidence against him being several songs of liberty which he had written. After several months' confinement he was discharged without a trial, but informed that he would not be permitted to pursue his studies at the Prussian universities. He accordingly went to Jena, where he took his degrees in 1820, subsequently continuing his studies at Halle and Dresden. When the Greek revolution broke out, young Lieber instantly resolved to take part in the struggle for

Grecian independence. He made his way with great difficulty to Marseilles, travelling much of the way on foot, and thence embarked for Greece. His experiences there are recorded in his *Journal in Greece*, published at Leipsic in 1823, and at Amsterdam in the same year under the title of *The German Anachorist*. Returning from Greece after the failure of the struggle, he landed at Ancona, and proceeded to Rome. There he made the acquaintance of Niebuhr, then Prussian ambassador to Rome, who took great interest in him and employed him as tutor to his son. He lived a year in the family of the historian, a period of his history which he afterwards embalmed in his *Reminiscences of Niebuhr*, first published in America, and afterwards in England. Returning from Rome to Berlin in 1823, he was soon again arrested by the Prussian authorities on the old charges of enmity to the Government and advocating republican opinions, and was imprisoned in the bastille of Koepnick, but was released after some months' confinement through the influence of Niebuhr. In 1825 he abandoned his country, and after spending a year in London went to the United States (1827), and as soon as possible was naturalized as a citizen of that country. Lieber took up his residence at Boston, and was occupied for five years in his laborious work *The Encyclopedia Americana* (13 vols.). In 1829 he removed to New York, where he published a translation of De Beaumont and De Tocqueville's work on the penitentiary system, with many notes. In 1833 he went to Philadelphia to prepare a plan of education for Girard College, then newly founded. While there he published *Letters to a Gentleman in Germany* and a supplement to his *Encyclopedia*. In 1835 he was appointed professor of history and political economy in South Carolina College at Columbia, S.C., where he remained more than twenty years, and during this period wrote and published the three great works upon which his fame as a writer chiefly rests—the *Manual of Political Ethics* (1838), *Legal and Political Hermeneutics* (1839), and *Civil Liberty and Self Government* (1853).¹

In 1856 Lieber resigned the professorship in South Carolina College, and was immediately elected to a similar professorship in Columbia College, New York, and to the chair of political science in the law school of the same institution. He continued in the discharge of the duties of these positions until his death, which occurred October 2, 1872. During the great war for the preservation of the Union from 1861 to 1865, Lieber rendered services of great value to the Government of his adopted country, and was frequently consulted by the secretary of war. He was one of the first to point out by his pen the madness of secession, and was ever active in supporting the Government and upholding the Union. He prepared, upon the requisition of the president, the *Code of War for the Government of the Armies of the United States in the Field*, which was adopted and promulgated by the Government in General Orders No. 100 of the war department. This code has been characterized by many European publicists as a masterpiece, and it suggested to Bluntchli his codification of the law of nations, as may be seen in the preface to his *Droit International Codifié*. During this period also Lieber wrote his *Guerrilla Parties with Reference to the Laws and Usages of War*, a valuable contribution to the law of war. At the time of his death he was by appointment of the Government of the United States the umpire of the commission for the adjudication of Mexican claims. The political writings of Francis Lieber are held in great estimation by all publicists. Sir Edward S.

¹ New editions of these works and of his miscellaneous writings have been published recently at Philadelphia.

Cressy, in his *First Platform of International Law*, alluding to his death, has justly said of him, "America and the civilized world in general have lately had to deplore in his death the loss of one whom the French jurist M. Laboulayes truly styled 'une des figures les plus originales parmi les urgenssables de notre temps'."

Beside the works already mentioned, Liebig published at various times many smaller works and pamphlets on different subjects, all of which attracted public attention, such as *The Origin and Development of the First Constituents of Civilization*, *Great Events Described by Great Histories*, *Essays on Property and Labour*, *The Laws of Property*, *Penal Laws and the Penitentiary System*, *Prison Discipline*, *The Relation between Education and Crime*, *The Fading Power*, *The Character of the Gentleman*, *International Copyright*, *Law a Bredman's Vocal Sounds*, *On Anglican and Gallican Liberty*, *The Post Office and Postal Reform*, *Independence of the Judiciary*, *Nationalism*, *Rise of the Constitution* (an unfinished work), and many minor tracts and publications. These works are all written with as much ease and purity of idiom as if English had been his native tongue, a fact not more remarkable than that he, a German, should have become the great American teacher of the philosophy of Anglian political science. (M. R. T.)

LIEBIG, JUSTUS (1803-1837), was born at Darmstadt in 1803. His father earned on business as a dyersalter and dealer in dye-stuffs, and made various experiments with a view to improved methods of preparing and purifying his wares. These led the son to take an interest in chemistry, and to seek for knowledge in the chemical books and periodicals in the grand-ducal library, which is rich in scientific works. At home he employed his time in repeating, as far as the means at his command admitted, the experiments he found described in books, and thus while still a boy attained a theoretical and practical knowledge of chemistry comparable with that of many full-grown professors of the science. He determined to be a chemist, to devote his life to the pursuit of science. The only kind of chemist available for teaching purposes was the chemist and druggist, and accordingly Liebig, at the age of fifteen, entered the shop of an apothecary at Heppenheim near Darmstadt to study chemistry. He soon found out how great is the difference between practical pharmacy and scientific chemistry, and returned to Darmstadt, after ten months, to look for another and more likely way of attaining his object. After some months spent in study at home he entered the university of Bonn, which he soon left for Erlangen. There he attended the lectures of Kastner on chemistry, and, beside the study of allied sciences, devoted some time to make up for the almost total neglect of school work caused by his early love of chemistry. He was much influenced by the metaphysical speculations of Schelling, and in after life referred to this influence as injurious to him as a scientific investigator. In those days there were no laboratories accessible to ordinary students, and Liebig had to content himself with what the university could give him in the lecture-room and in the library. Both at Bonn and at Erlangen he formed a students' chemical and physical society for the discussion of new discoveries and speculations as these appeared in scientific books or periodicals. In 1822 he left Erlangen with the degree of Ph.D. By means of the liberality of Louis I., grand-duke of Hesse-Darmstadt, Liebig was enabled to continue his chemical studies in Paris. There he made the acquaintance of Runge, Mitscherlich, and Gustav Rose. He attended the lectures of Gay-Lussac, Thénard, and Dulong, and, while carrying on the investigation into the composition and properties of the fulminates which he had already partly published, he attempted, as at Erlangen, to work up his neglected school studies. The results of his work on the fulminates were communicated to the Academy of Sciences, and attracted the favourable attention of Humboldt, who was at that time in Paris. Humboldt introduced Liebig to Gay-Lussac, who admitted him into his private laboratory as a pupil. Here he had opportunities of learning all the mysteries of the art from

one of the most skilful and ingenious of experimenters. It was on the advice of Humboldt that Liebig determined to become a teacher of chemistry, but difficulties stood in his way. As a native of Hesse-Darmstadt, he ought, according to the academical rules of the time, to have studied and graduated at the university of Giessen, and Humboldt had to use his influence to induce the authorities to forgive his having attended the foreign university of Erlangen. After examination his Erlangen degree was recognized, and in 1824, in his twenty-first year, he was appointed extraordinary professor of chemistry in the university of Giessen. Two years later he was promoted to the post of ordinary professor, which he held for twenty-five years, notwithstanding the most tempting offers from other universities. It was here, in the small town and small university of Giessen, that by far the most of Liebig's work was done. He began by remedying the evil which as a student he had himself felt. He induced the Darmstadt Government to build a chemical laboratory in which any student of the university might obtain a thorough practical training. It is difficult for us, who live in a time when nearly every university and many schools possess well-arranged and often well-endowed laboratories, to understand how great a revolution was made in the practical teaching of physical science by the foundation of the Giessen laboratory. We can form some idea of it by reading Liebig's articles on the condition of chemistry in Austria and Prussia, in which he goes over in detail the means of teaching afforded in the various universities of those great countries. He tells us that in 1838 two young Prussians came to Giessen to study chemistry, unable to obtain entrance to a laboratory in their own country, but were ordered back again by the Prussian Government. Fortunately other Governments were less strict, or other students were less obedient, and crowds of young men anxious to study chemistry came to Giessen, and carried home the light there acquired. Partly by Liebig's urgent appeals to the interests and to the shame of the great German states, partly by the influence of his pupils, a great reform was effected, and German universities now vie with one another in offering opportunities of practical instruction in chemistry and the other physical sciences.

The amount and the importance of the laboratory work done by Liebig in Giessen were very great. Without considering here the work done by his students under his direction, of which no doubt a very large part was conceived by him, and in the execution of which he constantly contributed his assistance and advice, we shall look only at what appears under his own name. During the twenty-six years he spent at Giessen as ordinary professor, he contributed to scientific journals more than two hundred papers, about twenty of which were records of joint work, chiefly with Wohler. During the same time he published his works on organic analysis, organic chemistry, chemistry applied to physiology and agriculture, his *Chemical Letters*, and many smaller treatises. From 1832 he was joint editor of the *Annalen der Pharmacie*, from 1837 of the *Handwörterbuch der reinen und angewandten Chemie*, and from 1847 to 1856 of the *Jahresbericht der Chemie*. These statements give some idea of the amount of his work; of its importance and of its effect on the history of science we shall speak later.

In 1845 he was raised to the hereditary rank of baron under the title of Freiherr von Liebig. In 1852 he accepted the invitation of the Bavarian Government to the ordinary professorship of chemistry in the university of Munich. This office he held till his death in 1873.

In private life Liebig was hospitable, courteous, and kindly. Honoured by all the great scientific societies of the world, and regarded by almost every one as the great authority in chemistry, he assumed no airs of superiority,

and lived the simple and quiet life of a German professor. Liebig's influence on the history of chemistry may be considered under five heads—(1) the effect of the opening of the Giessen laboratory, and of Liebig's constant efforts to induce other universities to follow this example; (2) the improvements introduced by him in methods of investigation and in apparatus; (3) the discovery of new facts; (4) the development of theory; and (5) the application of chemistry to physiology, agriculture, and the arts.

We have already spoken of the first. Under the second head by far the most important change introduced by Liebig was his method of organic analysis. Organic substances were analysed, and analysed with accuracy, before 1830, but such analyses could then be carried out only by highly-skilled chemists, and involved great labour and the use of cumbersome apparatus. Liebig's method of organic analysis, which was published in all its details in 1831, and which (with important but secondary improvements) is that still used, made it easy for any advanced student to make a fairly accurate and very useful analysis of an organic substance. Analysis as to the chemical and astronomical methods for determining longitudes and latitudes are to the geographical explorer. Without it many interesting and useful discoveries may be made, but it is only when complete and accurate analyses are made of all the new substances produced in the course of a research that the research becomes fully valuable to other explorers. If Liebig had cultivated nothing in organic chemistry but his method of analysis, he would still have been in a precisely true sense the founder of modern organic chemistry. Many other improvements of apparatus are due to him, we need only mention the simple form of condenser called by his name, and constantly used by every chemist, and the easy and accurate method for determining the quantity of urea in a solution, which was the first step towards introducing precise chemical methods into practical medicine. This is also the proper place to refer to his analyses of the natural alkaloids, and his discovery of the means of determining their equivalents by the analysis of their chlorhydrates. In the third place we have to consider the new facts discovered by Liebig. The very great addition to our knowledge of organic chemistry made by Liebig naturally throws into the shade his contributions to inorganic chemistry, but we ought to remember his famous analyses of mineral waters and his constant interest in the difficult question of the accurate separation of cobalt and nickel. It is, however, in organic chemistry that Liebig's great discoveries were made. These discoveries are so intimately connected with his chemical theories that we may most conveniently consider them along with the fourth head, his contribution to chemical theory.

The notion of compound radicals is to be found in chemistry as far back at least as the time of Lavoisier. Lavoisier says, "Some experiments of my own and some made by M. Hassenfratz have convinced me that in general nearly all the vegetable acids such as tartaric, oxalic, citric, malic, acetic, pyrotartaric, pyromucic acids, have for their radical hydrogen and carbon, but united we so to form a single base, that all these acids differ from one another by the difference in proportion of these two substances and the degrees of oxidation." Berzelius adopted this view and expressed it thus,—
"We find the differences between organic and inorganic bodies to be that, while in inorganic nature all the oxidized substances have a simple radical, all the organic substances have compound radicals. Just as ammonia is an alkali with a compound radical, but possessing nevertheless the greatest analogies with the mineral alkalis which have simple radicals, so we find the greatest analogy between the mineral and the organic acids, so that the relations of potash and soda to nitric, oxalic, nitric acids are the same as their relations to sulphuric, nitric, phosphoric acids." These views were published by Berzelius in 1817. In 1816 Gay-Lussac had discovered cyanogen, and shown that this compound of carbon and nitrogen is the radical of prussic acid and the salts in the same sense as chlorine is the radical of hydrochloric acid and the chlorides. Ampère had indicated a theory of the constitution of the ammonia salts, which Berzelius worked out in detail, according to which these salts contain a compound radical, ammonium, playing in them the part of potassium in the potash salts. Finally, Davy suggested in 1815 that the hydrated acids which correspond in function to hydrochloric acid should be regarded as the true acids, and proposed to represent them as compounds of hydrogen with a radical.

Such were the knowledge and the theoretical position of chemists on this question when Liebig became professor, the dates to which we have referred correspond to the time when as a schoolboy he was devouring the contents of chemical journals at Darmstadt, and no doubt he then became acquainted at first hand with the discoveries and speculations of Ampère, Davy, Gay-Lussac, and Berzelius.

We have seen that his first investigation referred to the fulminates. He continued his researches upon the compounds of cyanogen and the substances connected with them formal frequent

analyses of his researches during his whole life. In this region of organic chemistry he made many important discoveries, of which the limits of this article do not allow a detailed account; we can only mention melonic, melanic, ammeline, ammeline, and melamine, as substances discovered and investigated by him. In the course of these investigations he discovered the fusible nature of the chemical changes which occur in the manufacture of bromide of potash. In 1831 he examined the action of chlorine upon alcohol, among other substances discovered chloral, and commenced the series of investigations into the derivatives of alcohol and ether to which we shall refer immediately. In 1839 Wöhler and Liebig published the results of their joint research on the oil of bitter almonds and its derivatives. This research may be said to stand at the head of modern organic chemistry. For elegance of method and for clearness of insight it is unrivalled, and will always remain a model of what such an investigation should be. They showed in the clearest manner that the compound C_6H_5O (here and elsewhere in this article we use the symbols now in common use, instead of those employed by the authors), to which they gave the name of benzoyl, is the constant part, or radical, of a great series of compounds. The importance of this investigation was generally recognized. Berzelius hailed it as the advent of real daylight on the subject of organic chemistry, and even suggested the names pin or ethrin (from *pin* and *ethers*) for the newly discovered radical.

We now come to the long controversy as to the constitution of alcohol and ether, which engaged so much of Liebig's time and energy. Gay-Lussac had shown in 1816 that alcohol and ether might, for as their composition is concerned, be represented as compounds of olefiant gas and water, and further, that, if we represent the quantities by volume of gas or vapour, ether contains one volume of olefiant gas and half a volume of water vapour, while alcohol contains equal volumes of the two. In 1838 Dumas and Boullay published an elaborate memoir on the preparation and properties of the ethers, in which they further developed the ideas suggested by Gay-Lussac. They regarded olefiant gas as the radical of all the etheral compounds, as ammonia is of the ammoniacal salts, and formulated them thus—

	Base	Acid	Water
Sulphuretted	NH_4	HCl	
Muriatic ether	C_2H_4	HCl	
Nitric of ammonia	NH_4	HNO_3	H_2O
Nitrous ether	NH_4	HNO_2	H_2O
Ether	C_2H_4	H_2O	H_2O
Alcohol	C_2H_4	H_2O	H_2O
Alumina solution	NH_4	H_2O	H_2O

We have given only a sample of their tables, leaving out among others some substances in reference to the composition of which they had not made quite a sure case, since Liebig's theory was used as an argument, valid enough then no doubt, but of little interest now.

In 1833 Liebig proposed a quite different theory, one which stands to Dumas and Boullay's in the same relation which the ammonium theory holds to the ammoniac theory of the constitution of the ammoniacal salts. Just as Ampère and Berzelius regarded ammonium, not as NH_4 , HCl , but as NH_4Cl , so Liebig proposed for muriatic ether the formula C_2H_5Cl instead of C_2H_4HCl . The really cogent argument which he brought forward, the argument which we can now best appreciate, is that, while alcohol contains combined water, ether does not. According to Dumas and Boullay alcohol and ether are both hydrated, but in Liebig's view ether is $(C_2H_5)_2O$ and alcohol $(C_2H_5)_2O.H_2O$. If we wish to understand this argument we must recollect that to the chemicals of that time oxidized hydrogen was water, and Liebig's arguments are as sound now as they were then, for the most recent views represent alcohol as C_2H_5O and ether as $C_2H_5OC_2H_5$, and thus contain combined hydrogen, or, as we may say, half a molecule of water, and Liebig's tests do not distinguish preformed water, but hydrogen and oxygen combined as they are in water. Much debate and investigation followed, in the course of which the relations of all the substances derived from alcohol were thoroughly and practically studied in a fuller and more careful manner than would have been possible had there not been a theoretical point to defend and to attack. The enormous number of facts discovered by Liebig put him in a very favourable position as the advocate of his theory. Chemists could not do without a knowledge of these facts, and they could only get this knowledge through Liebig's papers, in which the facts were expressed in the language of his theory.

In 1835 Regnault began a series of most important researches into the compounds derived from olefiant gas. He showed that many of these substances might be classified and their relations explained by the assumption of a radical C_2H_4 , to which he gave the name of ethyl. Liebig gave the name of *etheral* to the C_2H_5 part of the meaning of the word radical, as "the unchanging constituent in a series of compounds," the same radical may be assumed in alcohol and in acetic acid, and in 1839, in a note published in the *Annalen*, he puts the matter in a very clear light. He says, "Ether and ammonia have in their compounds a certain resemblance which was

first introduced by Dumas and Berzelius, and the view of the constitution of the ammonia salt; which is generally held in France was the reason why ether was considered the first hydrate of elefant gas, alcohol as the second hydrate, &c., in Germany and other countries the water necessary for the constitution of the salts of ammonia with oxygen bases was considered as an integral part of the base. It was assumed that thus water forms with the ammonia salts of ammonium (NH_4O), and this view in a certain sense smoothed the way for another, according to which the existence of organic oxides, capable of neutralizing acids, appeared very probable, as a necessary complement to the organic acids which chemists had long been inclined to regard as species of organic radicals. Ether was in these countries regarded as an organic radical, and this difference of view excited a ten years' strife, as an immediate result of which we may regard the discovery of a great number of compounds which carried science with innumerable important observations. No region of organic chemistry has been so thoroughly and so completely studied as the compounds connected with ether, and now, when the existence of organic oxides is no longer denied, the support of the opposite opinion has come to an end, although it cannot be said that the question itself has been experimentally decided. If we compare in the light of our present knowledge the ammonia compounds with the ether compounds, we at once see that the opposing views were fundamentally the same in the two cases. The dispute took place because we were not at one as to the interpretation of the phenomena. The ether and ammonia compounds assume in fact the same form if ammonium is regarded as the unchanged radical of the ammonia compounds, and acetyl (Regnault's aldehydyl) as the stating point of the ether compounds. The two sets of compounds differ only in so far as we must ascribe to acetyl the power of forming acids, a power which ammonium does not possess.

He then gives a table containing in two columns the ammonia and the ether compounds, in which C_2H_5 corresponds to NH_3 , C_2H_5 to NH_2 , and C_2H_5 to NH , and acids. "These formulae require no explanation, they have been developed in order to show the extraordinary resemblance of the ammonia and the ether compounds, and to show why it was that many chemists regarded elefant gas as the first member of the series of ether compounds. Both of the formerly antagonistic theories have, as may be easily seen, from this point of view the same foundation, and all further questions as to the truth of the one or other view is thus of course at rest."

It was during the course of the controversy which then closed that Liebig had discovered aldehyde, chloral, and simultaneously with Soubeiran, chloroform, besides numerous other substances of less general interest, and developed the theory now generally received of the formation of ether by the action of sulphuric acid on alcohol. In the very first number of the series of ether compounds, as to the constitution of ether, we mentioned that Liebig's ethyl theory was to some extent borrowed from Berzelius. Berzelius had suggested that ether was the oxide of a radical (Liebig's ethyl), but he was at first inclined to regard alcohol, not as the hydrate oxide of the same radical, but rather as the oxide of another one, which with our symbols would be written C_2H_5 . But there was a deeper difference than this between the radical theories of Berzelius and Liebig. This essential difference first clearly showed itself in the notes which Liebig added to two letters from Berzelius to Wohler, published in the *Annalen* in 1859. In these letters Berzelius gives his views of the constitution of oxyhalides, with which he classes such bodies as trichloroacetic acid. All those bodies he represents as compounds of oxides and chlorides, in harmony with the dualistic system.

Thus, instead of SO_2Cl_2 , $\text{C}_2\text{H}_5\text{ClO}_2$, &c., he writes $\text{SO}_2 + 2\text{SO}_2$, $\text{C}_2\text{H}_5 + \text{C}_2\text{H}_5\text{O}_2$ (as taking the anhydrous acid). In his second letter on Liebig's chlorides, where he naturally arrives at formulae of extreme complexity. In his notes Liebig states that he does not agree with Berzelius, and that the analogy first pointed out by Berzelius between inorganic and organic compounds and his theory of organic radicals had been a guiding star in a labyrinth in which previously no one could find the way. "But, while there are points of resemblance, there are very many points of difference; we should follow a theory as long as it gives us light and explains facts; up to a certain point the principles of inorganic chemistry help us in organic chemistry, beyond if they leave us, and produce instead of removing complications; beyond this point we require new principles."

These new principles were supplied by Liebig's radical theory. As Liebig showed, abstract discussions as to the truth of a theory are out of place in an experimental science; the question is not as to their essential truth but as to their practical fruitfulness. Do they help us to understand old and to discover new facts? If they do, the morrow may take thought for its own theories. These are not Liebig's words, but they seem to express his ideas.

Liebig early expressed his approval of Davy's views as to the constitution of acids, but he rarely used the language or the notation corresponding to his view. This divergence between his theory and his habitual language is interesting as showing that he held

that the same truth may be expressed in more than one way, and that where no immediate point is to be gained it is well to employ the language best understood by those whom we address. In this, as in his preference for what was called the equivalent system of notation over that of Berzelius, he showed his sound practical judgment and common sense. We now see that the notation of Berzelius was nearer to the truth, but its advantage could not be felt until chemistry had advanced further, and its retention would have led to complications of formulae and obscuring of relations. The resemblance indeed of our present notation to that of Berzelius is to a great extent accidental, and the advance was hastened rather than hindered by what now looks like a retrograde step.

There is one other point which we have to mention under the present head. Liebig at once saw the importance of Graham's researches on the phosphates. He applied Graham's idea of polybasicity to organic acids, and satisfactorily proved, notwithstanding the opposition of Berzelius, that tartaric acid is dibasic and citric acid tribasic.

We have hitherto said nothing as to the relation of Liebig's theories to those at present held by chemists. On this subject a word may suffice. The great revolt against the radical theory led by Laurent and Gerhardt produced a long and acrimonious controversy. In this controversy Liebig took his part, and many laws and some unfair things were said by him. The controversy itself was of course the means of producing a vast amount of thorough research, and was thus, like all such contests, of direct use, it also led to the revision of all theoretical opinions from a totally new point of view. From this point the radical theory has emerged, not very different in appearance, but it has undergone a profound change. Its foundations have been immensely strengthened, it has been to a great extent explained. Some chemists seem to think that this makes it an entirely new theory. We cannot share this view. Our reasons for believing in ethyl and benzyl differ from the reasons adduced by Wohler and Liebig only in this, that we have arguments which they had not, then arguments remain. We now know something of the reason why such radicals exist, we can, to a certain extent, deduce their properties from those of the elements which they contain, but explanation is something different from refutation. The radical theory has grown, but it has not been destroyed.

Liebig all his life showed a special predilection for the study of the immediate products of animal life. He investigated with untrusting zeal the substances contained in urine and in the juice of flesh. In these researches he discovered many new substances, and cleared up details and difficulties as to their relations to one another and to other bodies. Late in life he expressed the most lively interest in Volhard's synthesis of sacrosin and creatins, substances with the preparation of which he had long before been engaged. In this connection it is right that we should mention his elaborate investigation on urea acid and its derivatives. This line of study led him to interest himself in the chemistry of food, and the importance of his work in this direction can scarcely be overestimated. We do not refer alone to his methods of preparing the extract of meat and the food for infants, which have perhaps spread his fame more widely than his strictly scientific work could have done; we refer rather to the influence which his analyses and calculations have had on medical opinion and practice. And this leads us to our fifth head, Liebig's influence on the application of chemistry to physiology, agriculture, and the arts.

Before Liebig undertook his investigations into the chemistry of vegetables, the views (they are sometimes called theories) held as to the manner in which plants are nourished were vague in the extreme. The only point satisfactorily made out was that under the influence of light the green parts of plants are capable of decomposing carbonic acid, giving off oxygen and retaining the carbon. Some of the most careful experiments on the cultivation of plants, first noted by Priestley, is mainly due, believed that the nitrogen of the plant came from soluble organic substances absorbed by the roots, and expressly says that the main use of ammonia in manure is as a solvent of humus, which he supposed to be one source of the carbon in plants, and that although the case of the one plants had been analysed, the importance of the mineral constituents of vegetables was not at all recognized. Liebig undertook the investigation of this question in 1840. He showed that the plant derives its nourishment partly from the air, partly from the soil; the carbonic acid and water, and the carbonic acid, which he showed to be the source of the plant's nitrogen, comes from the atmosphere; while the potash, soda, lime, iron, magnesia, sulphuric acid, phosphoric acid, and silica come from the soil. No exhaustion can take place of the former, but the soil contains only a limited amount of the latter in a soluble state, and when this is used up the soil becomes barren. He showed that the soil contains any one of the necessary substances makes the soil barren. He showed how manure acts by restoring these deficient ingredients, and how, when the land is left fallow, atmospheric influences decompose the insoluble minerals and supply the soil with what has been removed. He further showed that plants can take their nourishment from the soil the articles of plant food in various proportions,

and thus explained the submergence of a rotten crop. The animal and human body he reproduced contained the essential animal substances, and a small quantity of mineral salts, because he held that while the animal supplies ammonia it does not always supply at first enough, particularly to the less fatty parts. He bought a bull not to test his experiments, and treated it with the artificial manure, but the result was disappointing. The manure was not inactive, but not nearly so active as it should have been. It was many years before he detected the cause. To prevent the manure wasting away the alkalies in the manure, he had taken great pains to render them insoluble. Way's experiments on the absorption of manure by the soil (1850) confirmed him in his suggestions. In 1857, I wished to improve his soil, and in my blindness believed that, in the marvellous chain of laws leading life on the earth's surface and keeping it always warm, a link had been forgotten which I, weak mortal, could not supply.

Now, just as he showed that plants require carbon—often small quantities of particular substances, for they will not grow at all, however great may be the quantities of other kinds of food supplied, so he showed that animals also require, not only a proper quantity of food, but also the right proportion of the different kinds of food, animal as well as mineral. In the classification of the kinds of organic food into hydrocarbon and alcohol, it was necessary to examine whether the (alcoholized, starch, sugar, &c.) should be placed alongside of fat. It was thus led to inquire into the power of the animal body to produce fat from starch or sugar, and came to the conclusion, contrary to the opinion of Dumas and Berzelius, that the fermentation does take place.

Liebig's investigations into the relations of organic chemistry to physiology led to the conviction that the only source of animal heat is the heat produced by the oxidation of the tissues, and, strange as it may appear, he had to defend this view against what he truly enough, though not quite justly, called the "phlogiston" of his medical opponents. He also succeeded in demonstrating, it is to be hoped finally, the ridiculous belief in the possibility of the spontaneous combustion of the human body.

Liebig's theory of FERMENTATION (*of r*) aimed at explaining the phenomena on purely chemical principles. He introduced the physiological theories, and looked upon the growth of fungi rather as inevitable of the fermentation, adding the fermentative changes of amygdaline and similar substances as cases of fermentation without life.

We have still to notice one of Liebig's chemical discoveries, of secondary interest chemically, but of great practical importance. This is his discovery of a method for depositing a uniform film of metallic silver on smooth clean surfaces. This method may render it possible to use reflectors for astronomical telescopes of a size unattainable with the old speculum metal.

The most important of Liebig's works separately published are as follows:—*Lehrbuch der Analytischen organischen Chemie*, 1835, 41, 42, 1858. *Der Chemie in ihrer Anwendung auf Agrikultur und Physiologie*, 1840, 9th ed., 1875-76. *Die Theorie der Gärung und die Gärungschemie in ihrer Anwendung auf Fäulnis und Pathologie*, 1842, 3d ed., 1847. *Handbuch der Chemie und Technologie für Pharmazeuten*, 1841, vol. 1 of *Becker's Handbuch der Pharmazie*, new ed., Chemische Reihe 1844, 6th ed., 1859. *Chemie in ihren Anwendungen auf die Naturgeschichte und die Technik*, 1847. *Grundriss der Agrikultur-Chemie*, 1855. *Der Thee in Paris und der Ländliche Thee*, 1856. *Naturgeschichte der Luft* also the *chemische Landwirtschaft*, 1859. *Lehrbuch der Agrikultur-Chemie*, a p. volume collection of some of his addresses and shorter publications. Liebig's scientific papers were chiefly published in *Poggendorff's Annalen* (1839), and in *Liebig's chemische Annalen* (1840 and 1864, and also as a separate publication). (C. G. B.)

LIECHTENSTEIN, a sovereign and independent principality, the smallest in Germany, is bounded on the N E and E by the Austrian Vorarlberg, on the S, by the Swiss canton of Grisons, and on the W. by the Rhine, while on the north it tapers almost to a point. The state, consisting of the lordships of Vaduz and Schellenberg, is only 15 miles in length, hardly over 5 miles in its average breadth, and comprises an area of 68 square miles. Excepting in the immediate neighbourhood of the Rhine, the surface of the country is mountainous, being traversed from south to north by spurs of the Ebneth Alps, which at some points attain an altitude of about 7000 feet. The climate is mild, and the soil generally fertile and well watered. The chief products are corn, wine, flax, fruit, and timber. Agriculture and the tending of cattle form the chief employment of the inhabitants. A branch of the Vorarlberg railway from Feldkirch to Buchs passes through

the state. In 1876 the population amounted to 8664, of old German extraction, and Roman Catholics by confession. The capital is Vaduz or Liechtenstein, with 960 inhabitants.

Until 1862 Liechtenstein formed part of the German confederation, but from that date it has been constitutionally independent, although for the sake of convenience the postal system, customs, and currency are under the general Austrian administration, from which the principality receives annually some £1000 as its share in the customs dues. According to the charter of the 28th September 1862, Liechtenstein is a constitutional monarchy, the sovereign prince sharing the legislative power with a diet of fifteen members (elected biennially), of whom three are nominated by the prince, and twelve elected by popular suffrage. The chief control of the principality is vested on the prince by a court of honour, which also serves as the judicial court of appeal of first instance, the ultimate court of appeal being at Innsbruck. The immediate direction of the principality in administrative and judicial matters is at Vaduz. The inhabitants are free from military service and direct taxation. The annual revenue amounts to about £8000. Although the sovereignty of the prince is so small, his estates in Austria and elsewhere render him one of the wealthiest landed proprietors in Germany, his income from them amounting to nearly £240,000 sterling. The house of Liechtenstein, one of the oldest in Central Europe, was elevated to the princely dignity in the early part of the 17th century. Anthony Florian in 1715 obtained a vote and seat in the imperial diet, and after the union, in 1718, of the lordships of Vaduz and Schellenberg into one principality under the name of Liechtenstein, his privileges were, in 1723, confirmed to his successors. See Jacob von Falke, *Geschichte des fürstlichen Hauses Liechtenstein*, 2 vols. (Vienna, 1898-77).

LIEGE (Germ., *Lüttich*, Dutch, *Luik*, Walloon, *Lige*; usually Latinized as *Lecodum*), a city of Belgium, the chief town of the province of Liège, is situated in 50° 39' N lat. and 5° 31' E long, 56 miles east of Brussels (82½ by

Plan of Liège

rail), and 16 miles south-west of Maestricht. It occupies a remarkably fine position on the banks of the Meuse, which at this point is joined by the Ourthe. On the left-hand side stands the older city with the citadel and the more important historical buildings, on the right hand lies the lower and more modern portion, commanded by the fort of the Chartreuse. The river, there 460 feet across, is spanned by several bridges, of which the Pont des

Archés, rebuilt in 1860-63, dates originally from the 8th century, and plays a prominent part in the local annals. Place St Lambert is the historical centre of Liège. Here still stands the noble building—erected (1508-40) by Cardinal de la Marck in a late Gothic style—which down to the revolution was the palace of the prince-bishops, and is now with its modern extensions occupied by the public courts and other administrative offices. And here, till it was raised by the revolutionists in 1794, and completely removed in 1808, stood the old cathedral of St Lambert, originally founded in 712, and rebuilt after a great fire at the close of the 12th century. The rank of cathedral was in 1802 transferred to the abbey-church of St Paul, the foundation of which is assigned to 958, though the nave is no older than the 16th century, and the choir belongs to 1280. The stained glass and the wood carving of the pulpit by Ceefs deserve particular mention. Other churches of note are St Jacques, a fine Gothic building founded in 1016, with a Romanesque west tower and polygonal choir; St Barthélemy, a completely modernized basilica of the 13th century; St Martin, founded in 962 and rebuilt in the middle of the 16th century; and the Holy Cross, founded by Nolker in 973, with a west choir dating from the 12th century, and the east choir and nave from the 14th. The university of Liège, established in 1317, is a flourishing institution, with about 40 professors and 800 students, a library of 100,000 volumes, a botanic garden (1819, formerly the Jesuits' garden), a school of mines (1825), a school of arts and manufactures, a normal grammar school, and several other auxiliary foundations. There is no theological faculty, the theological seminary, with a large library of its own, being an independent institution. The city further possesses a blind asylum, a deaf and dumb institute, school of design, painting, and music, a zoological garden, a municipal museum, &c. The Place d'Artois is adorned by an equestrian statue of Charlemagne by Jéhotte, and in front of the theatre stands a bronze statue of Gretry, the composer, who was born at Liège.

Liège is the centre of a great mining district rich in coal, lead, zinc, and iron; the coal-mines extend under the city and the river. In 1879 358,100 tons of coal were raised in the province, 22,156 persons being employed in the pits. The iron, lead, and zinc foundries in the town and neighbourhood work up large quantities of ore in addition to the local supply. Steel, copper, and tin wares, steam-engines and general machinery, woollen goods, excellent saws and files, nails, needles, mirrors, clocks, leather, paper, and oil are among the products of the versatile industry of the place. Liège diamonds have long enjoyed a wide reputation. They give employment to about 30,000 workmen, who for the most part work in their own houses, though in 1873 a large factory was erected in the American style for making all parts of the weapon by machinery. In 1875 188,806 single-barrelled guns, 118,121 double-barrelled guns, 408,649 revolvers, 19,596 saddle pistols, and about 85,000 army weapons, &c., were passed by Liège through the Government testing office. The town is favoured by the fact that the town is an important junction on the Rhemish Belgian Railway, commands more than one navigable river, and has long been one of the leading cattle-markets in the country. The population was 115,956 in 1874.

About 720 the bishops of Tongres, after oscillating between Tongres and Maastricht, settled at Liège, though they did not take the title bishop of Liège for more than two centuries. Their church of St Lambert received large territorial endowments, and in the 14th century they became princes of the empire. For centuries the struggle was maintained between episcopal tyranny and civic independence; and feudal and imperial armies were called in to crush the insurrections. In this way Charles the Bold of Burgundy made himself master of the city in 1467, and again with much bloodshed and barbarity in 1468. Bishop Ferdinand in 1680 and Bishop Maximilian in 1884 were each imposed on the citizens by force of arms, and kept them down by means of a strong citadel and foreign soldiers. In 1691 Liège was bombarded for five days by Marshal de Boufflers; in 1702 Marlborough took the citadel by storm from a French garrison; and in 1792 the town was the scene of a great defeat of the Austrians by the French.

See *Reynard, Hist. de Liège*, *Reynard, Hist. de l'ancien pays de Liège*, and *Liège pittoresque*. *Polain and Baethem, Courumes du pays de Liège*; *Baron de Godefrid, Hist. de Liège* (2d ed., 1868); *Reynard, Biographie Liégeoise*.

LIEGNITZ, the capital of a district of the same name in the Prussian province of Silesia, is picturesquely situated on the Katzbach, just above its junction with the Schwarzwasser, and 40 miles west-north-west of Breslau. It consists of an old town, surrounded by pleasant, shady promenades, and several well-built suburbs. The most prominent building is the palace of the former dukes of Liegnitz, rebuilt after a fire in 1836, and now occupied by the administrative offices of the district. The Ritter Academie, founded by the emperor Joseph in 1708, for the education of the young Silesian nobles, was reconstructed as a gymnasium in 1810. The Roman Catholic church, with two fine towers, contains the burial vault of the dukes. The principal Lutheran church dates from the 14th century. There are also several other churches and schools, and a number of benevolent institutions. The theatre, the barracks, the military hospital, and the town-house are the most noteworthy of the remaining buildings. The manufactures of Liegnitz are considerable, the chief articles being cloth, wool, leather, tobacco, and pianos. Its trade in grain and its cattle-markets are likewise important. The large market gardens in the suburbs grow vegetables to the value of £20,000 per annum. Population in 1880 37,168, about one-fourth being Roman Catholics.

Liegnitz is first mentioned in an historical document in the year 1004. In 1164 it became the seat of the dukes of Liegnitz, who greatly improved and enlarged it, especially in 1170 and 1175. The dukes were members of the illustrious Piast family, which gave so many kings to Poland. At Wahlstatt, near Liegnitz, the tide of Mongol invasion was stemmed, in 1241, in a hard-fought battle between the Tartars and the Christian army under the duke of Silesia. The victory, indeed, remained with the invaders, but the obstinate resistance deterred them from any further attack on Germany. During the Thirty Years War Liegnitz was taken by the Swedes, but was soon recaptured by the Imperials. The Saxon army also defeated the imperial troops near Liegnitz in 1634. On the death of the last duke of Liegnitz in 1675, the duchy came into the possession of Austria, which retained it until the Prussian conquest of Silesia in 1740-45. In 1760 Frederick the Great gained a decisive victory near Liegnitz over the Austrians under Laudon, and in 1813 the last of important battles in the neighbourhood was completed by Blücher's defeat of the French at the battle of the Katzbach. During the present century Liegnitz has been uniformly prosperous, and its population has increased fivefold since 1800. See *Schuchard, Das Stadt Liegnitz* (Berlin, 1858); *Semmler and Krafft, Chronik von Liegnitz* (Liegnitz, 1861-78).

LIEN, in English and American law, properly means a right of detaining goods of another in your possession until a debt due to you from the owner of the goods is paid. To the original or common law conception of a lien it would appear to be necessary that the goods over which lien is claimed should be actually in the possession of the creditor, and further that the debt should have been incurred with reference to the goods which are detained. Such is the lien of the workman to whom articles are delivered for the purpose of being operated upon by him in the way of his trade. He is entitled to keep the article he has worked at until remuneration for his labour has been made to him. Of precisely the same character is the lien of the carrier over the goods conveyed by him, for the fare; or of the farrier over the horse which he has cured, for his fee; or of blacksmiths, shipwrights, and other artificers for the wages they have earned by working at or on the thing detained. Thus, the true lien of the English law, is denominated a particular lien in contradistinction to a right of detainer exercisable over the property of another, for a debt not incurred in relation to the thing detained. The latter is a general lien. The former is said to be favourably, the latter strictly, construed by the law. The former arises by implication of law from the relation of the parties; the latter requires a special contract either expressed in terms or to be inferred from the usage of trade. Again, as possession is the foundation of lien in common law, a parting with the possession would in general operate as a waiver

or forfeiture of the lien. The same effect would follow of course from any agreement by the lien holder to give up his right while retaining possession of the property. Again as a general rule lien men have only a right of detention, not a power of sale,—a fact which distinguishes it from a pledge of property in security for a loan. But in special cases power of sale have by statute or judicial decision been added to liens. Thus innkeepers now have, in addition to their ordinary right of lien, power to sell goods and chattels left with them after six weeks (41 & 42 Vict. c. 38). In the United States the principle of the particular lien has been developed in a notable manner in protecting the rights of workmen employed in building. At common law, the building belongs absolutely to the owner of the soil, and accordingly, when a house is erected by contract, the contractor may receive payment from his employer and may fail to pay the labourers he has employed, who are consequently left without redress. The "mechanics' liens," created by statute in several of the American States, give labourers a lien over the building which they have erected for their unpaid wages. Notice having been filed in the prescribed manner, they acquire a right to have their wages paid out of the property, with it may if necessary be sold for that purpose. A similar preferential charge, not depending on possession, is recognized by the law in various cases, and goes by the name of lien. Thus in equity an unpaid vendor has a charge for the amount of the purchase money, or the balance thereof, over the estate, although it may no longer be in his possession. Charges of this kind are sometimes denominated equitable liens. Of the same nature is the charge acquired over a ship by a person who has supplied her with necessaries for the voyage under a lawful contract with the master (maritime lien).

LIERRE, or LIÈGE, a town of Belgium, in the province of Antwerp, 9½ miles south-east of Antwerp (on the railway to Malines), at the junction of the Great and Little Noëthe. It is a busy place of 15,659 inhabitants (1874), and manufactures silk, lace, and shoes, beetroot sugar, and a peculiar kind of white beer known as *caveuse*. The church of St Gommaire (in plan a Latin cross with a lofty tower in front) is one of the most notable buildings of its class in Belgium. It was commenced in 1425, but not completed for more than a century. Of the fine stained glass windows three were presented by the emperor Maximilian.

LIÈGE, which dates from the 9th century, owed much to the favour of the dukes of Brabant, to whose territory it belonged. The more important facts in its annals are the celebration of the marriage of Philip the Fair with Joanna of Castile (1496), the residence in the town of Christian II. of Denmark during his exile, and the contests between the Dutch and Belgian forces in 1830. Joseph II. ordered the fortifications to be razed in 1784.

LIFE ASSURANCE. SEE INSURANCE.

LIFEBOAT. It will be convenient to consider here, not the lifeboat simply, but also other means of saving life at sea. When it is borne in mind that the vast commerce of such a country as Great Britain extends to every part of the world, that the arrivals and departures from the ports of the country in one year average six hundred thousand vessels, that these are manned by more than two hundred thousand men and boys, and carry goods to the estimated value of six hundred millions sterling, with unknown thousands of passengers, that its seaboard is nearly 5000 miles in extent, many parts of it being exceedingly dangerous to shipping, that about two thousand wrecks occur every year on its shores, and above seven hundred lives are lost, the necessity that exists for a well-organized system of life-saving apparatus becomes very apparent. It is satisfactory to be able to add that this well-organized system is most efficiently provided by the Royal National Lifeboat Institution, with its splendid fleet

of two hundred and seventy-one lifeboats, and by the Rocket Service. The number of lives saved annually, either by the lifeboats or by special excursions for which the institution has granted rewards, averages in round numbers nine hundred, and by far the greater proportion of these (four-fifths) are saved by lifeboats. These lifeboats, too, are the means of saving every year from twenty to thirty vessels which, owing to stress of weather, exhausted men, &c., would almost certainly have been lost but for the aid afforded by the fresh and experienced lifeboat crews.

The qualities of the lifeboat first deserve our attention. These are such that this boat is able to live in seas, and go into positions of danger, that would overwhelm ordinary boats or insure their destruction. Eight important qualities are possessed by it in a very high degree—(1) buoyancy, (2) great lateral stability, or resistance to upsetting, (3) the power to right itself if upset, (4) the power of immediate self-discharge when filled with water, (5) strength, (6) stowage room for a large number of passengers; (7) speed against a heavy sea, (8) facility in launching and taking the shore.

The buoyancy of the institution's lifeboat, or its inability to sink, be it ever so deeply laden, is secured chiefly by means of a watertight deck or floor, air-cases round the sides inboard, and two large air-chambers, one in the bow, the other in the stern. The "extra buoyancy" thus obtained cannot be too great so long as it does not interfere with the space necessary for working the boat and stowing shipwrecked persons. The air-cases round the sides serve also to confine any water shipped to the centre of the boat, a point of great importance. There is an airtight space between the boat's floor and its bottom, filled partly with air partly with cork-balling, which gives it additional buoyancy, but the air-chambers above the floor would float the boat even if she were stove in and this space filled with water. In a 33-feet boat the buoyancy obtained by all its chambers is equal to 11½ tons.

Stability is obtained chiefly by means of ballast. Immense difficulty was experienced in arriving at the present form of the institution's splendid boat, because qualities of differing value had to be sacrificed to each other in due proportion. Thus, while breadth of beam secured stability, it seriously interfered with the self-righting quality. Ballast, therefore, in the form of a heavy iron keel, instead of breadth, became necessary to give the requisite stability.

Fig. 1 represents, let us say, the 38-feet, double-barked, tanned, self-righting, and self-emptying lifeboat of the institution on its transposing carriage, ready for launching, figs. 2 and 3, respectively, a section and a bird's-eye view of the same. The

FIG. 1.—TEN-OWNED LIFEBOAT.

breadth is 8 feet, with stowage room for forty-three persons—thirty passengers and thirteen of a crew. The trestled lines (fig. 1) enable people in the water to clamber aboard, or, without assistance. The shaded parts of figs. 2 and 3 show the position of the air-cases. The white oblong space in fig. 3 shows the free space available for crew and passengers. In fig. 2 are seen the depth to which the air-cases descend, and the height to which the bow and stern air-chambers ascend above the gunwale, also the ballast space between the floor and the keel.

The self-righting power is due to the large elevated air-chambers in bow and stern, coupled with great sheer, or rise fore and aft, of gunwale, to the iron keel, which weighs

about 9 cwt in a 33-foot boat, and to the air-cases and ballast, which latter weighs from 7 to 8 cwt. When the boat is upset it cannot rest on its two elevated air-chambers, it necessarily rolls on one side, then the heavy iron keel and ballast come into play and drag it back to its right position.

FIG. 2—Lan.boat (Sheet Plan)

FIG. 3—Lifeboat (Deck Plan)

in a few seconds. This principle of self-lighting was discovered—at all events first exhibited—at the end of last century, by the Rev James Biemess of Orkney, but was not finally adopted till the middle of the present century.

The self-emptying quality depends chiefly on the well-known physical fact that water must find its level. The float of the lifeboat (fig. 2), the dotted double line extending from stem to stern, on which the men's feet rest when seated on the thwarts, is placed so as to be very slightly—2 or 3 inches—above the level of the sea when the boat is fully manned and loaded. In this floor there are six holes of 6 inches diameter, into which are fitted six metal tubes. These pass through the boat's bottom into the sea. The water of course enters them, but cannot rise above them into the boat, because it cannot rise above its own level. Valves at the upper ends of the tubes, opening downwards, prevent the annoyance of water spouting in, but allow it freely to run out. When, then, a billow overwhelms the boat, and fills it, the water rushes violently down the discharging tubes until it reaches the sea-level, by that time it has descended below the level of the floor and left the boat empty. So complete and swift is the process that a filled boat frees herself in about half a minute. This principle was first applied by the institution in 1851. Lifeboats devoid of the self-discharging quality become temporarily useless when filled by a sea, as they can be emptied only by the slow and laborious process of baling.

Strength, that will enable the lifeboat to suffer treatment which no ordinary boat could stand, is dependent on peculiarity of construction and material. The best Honduras mahogany is used, and the diagonal plan of construction adopted,—that is, the boat has two distinct "skins" of planking, both sets of planks being laid on in a position diagonal to the boat's keel and contrary to each other, besides passing round from gunwale to gunwale under the boat instead of from stem to stern as in ordinary boats. The skins have a layer of prepared canvas between them, and thus great strength and elasticity are combined.

The *carriage* of the lifeboat is an essential adjunct for the purpose of conveying it over any kind of road or beach to the place where it may be required. It can be run deep into a raging surf, and the boat, with its crew seated and oars ready out, can be launched at once, by blocks and tackle, so as to enable the men to dash forward and meet the incoming rollers with sufficient force to propel it through or over the seas, and thus avoid the risk of being hurled back on the beach. Each lifeboat is furnished with a set of spare oars, as these are frequently broken.

The institution's lifeboats are of various sizes—six, eight, ten, and twelve oared,—and they are placed at various

points of the coast according to the necessities of each station. Some are called out at long intervals, others, such as those near the Goodwin Sands, are constantly on duty in rough weather—that of Ramsgate having a steamer to attend on it, which lies in harbour, with its fires banked up, ready for instant action night and day. The average cost of a lifeboat station is £1000,—the boat and equipments, including belts and carriage, costing £550, and the boat-house £350. The average annual expense of maintaining a station is £70, which is expended in paying the crew for going off and saving or attempting to save life from shipwreck, for exercising the lifeboat once a quarter, paying coxswain's salary, replacing gear, and repairs.

The *lifebelt* of the institution is a part of the equipment of the lifeboat which merits special attention, because it is a very efficient contrivance, and has been the means of saving many lives in time past. Fig. 4 shows its appearance and the manner in which it is worn. It was designed in 1854 by Admiral J. R. Ward, the institution's Chief Inspector of Lifeboats. It is made of cork fastened on canvas, and contains great buoyancy with strength and flexibility. It not only floats a heavily-clad man head and shoulders above water, but enables him to support a comrade easily—the extra buoyancy being 25 lb. One of its distinctive features is its division at the waist, by which means great freedom of action is allowed. It serves also as a species of armour to protect the wearer's most vital parts from blows against rock or wreck, while it affords some degree of warmth. No man may serve in the lifeboats of the institution without it, and it would be well if every British ship were obliged to carry lifebelts of this kind.

FIG. 4

History.—The first lifeboat was conceived and designed by Lionel Lukin, a London coachbuilder, in 1785. Encouraged in his philanthropic plans by the prince of Wales (George IV.), Lukin fitted up a Norway yawl as a lifeboat, took out a patent for it, and wrote a pamphlet descriptive of his "Inamemorable Boat." Buoyancy was obtained by means of a projecting gunwale of oak and air-chambers inside—one of these being at the bow, another at the stern. Stability he secured by a false iron keel. The self-lighting and self-emptying principles he seems not to have thought of; at all events he did not compass them. Despite the patronage of the prince, Lukin went to his grave a neglected and disappointed man. But he was not altogether unsuccessful, for, at the request of the Rev. Dr Sharp, Lukin fitted up a coble as an "inamemorable" lifeboat, which was launched at Bamberough, saved several lives the first year, and afterwards saved many lives and much property.

Public anxiety in regard to shipwreck was at length swept away by the wreck of the "Adventure" of Newcastle in 1789. This vessel was stranded only 300 yards from the shore, and her crew dropped, one by one, into the raging breakers in presence of thousands of spectators, none of whom dared to put off in an ordinary boat to the rescue. An excited meeting among the people of South Shields followed; a committee was formed, and arrangements were entered for the best models of a lifeboat. This called forth many plans, of which those of William Wouldhave, a painter, and Henry Gienstead, a boatbuilder, of South Shields, were selected. The committee awarded the prize to the latter, and, adopting the good points of both models, gave the order for the construction of their boat to Greenhead. This boat was rendered buoyant by nearly 7 cwt of cork, and had very taking stem and stern-posts, with great curvature of keel. It did good service in after years, and Gienstead was well rewarded; nevertheless no other lifeboat was launched till 1798, when the duke of Northumberland ordered Greenhead to build him a lifeboat which he endowed. This boat also did good service, and its noble owner ordered another in 1800 for Oporto. In the same year Mr Cathcart Dempster ordered one for St Andrews, where, two years later, it saved twelve lives. Thus the value of lifeboats began to be recognized, and before the end of 1808 Greenhead had built no fewer than thirty-one boats—eighteen for England, five for Scotland, and eight for foreign lands. That these boats were lamentably insufficient to meet the necessities of England was shown year after year by the ever enlarging record of wreck and loss of life on her shores; nevertheless, public interest in lifeboats was not thoroughly aroused till 1828.

In that year Sir William Hillary, Bart., stood forth to champion the lifeboat cause. Sir William dwelt in the Isle of Man, had

assisted with his own hand in the saving of three hundred and five lives, and felt the horrors of shipwreck so keenly that he resolved to stir up public men and the nation generally to a sense of their duty in regard to this matter. Eventually, in conjunction with two members of parliament—Mr Thomas Wilson and Mr George Hibbert—he founded the "Royal National Institution for the Prevention of Life from Shipwreck." This, perhaps the grandest of England's charitable societies, and now named the "Royal National Lifeboat Institution," was founded on the 4th of March 1824. The king and many of the nobility and gentry patronized it. The archbishop of Canterbury presided as its patron; the next day the king—among them the Wilkes—pleaded the cause; the institution was launched under the most favourable auspices, and began its noble career with a sum of only £9826. In the first year twelve new lifeboats were built and placed at different stations, besides which thirty-nine lifeboats had been stationed on the British shores by benevolent individuals and by independent associations over which the institution exercised no control though it often assisted them. In its early years the institution placed the mortar apparatus of Captain Mauley at its many stations, and provided for the wants of sailors and other saved from shipwreck. The latter duty was soon efficiently discharged by the "Shipwrecked Fishermen and Mariners' Royal Benevolent Society." At the date of the institution's second report it had contributed to the saving of three hundred and forty-two lives, either by its own life-saving apparatus or by other means for which it had granted rewards. With fluctuating success, both regards means and results, the institution continued its good work from year to year—saving many lives, and occasionally losing a few brave men in its tremendous battles with the sea. District or branch societies were established in most of the coast towns. Ultimately it began to be recognized that inland towns owed something to the lifeboat cause, as well as towns on the coast, and now such cities as Manchester, Liverpool, Glasgow, Edinburgh, &c., have presented lifeboats to the institution and become annual contributors. Since the adoption of the self-righting boats, loss of life in the service has been comparatively small and infrequent.

Towards the middle of this century the lifeboat cause appeared to lose interest with the public, though the life-saving work was prosecuted with unremitting zeal, but the increasing loss of life by shipwreck, and a few unusually severe disasters to lifeboats, brought about the reorganization of the society in 1836. The late Prince Albert became the patron of the institution in conjunction with the late king of the Belgians, and afterwards Her Majesty the Queen, who had been its patron since her accession, became an annual contributor to its funds. About the same time its present secretary, Mr Richard Lewis, barrister-at-law, was appointed. The following year (1837) the Duke of Cumberland became its president, and from that time forward a tide of prosperity set in, which is literally unrepresented in the history of benevolent institutions, both in regard to the great work accomplished and the pecuniary aid received. Its flow of property has never since been checked. In 1850 its committee undertook the immediate superintendence of all the lifeboat work on the coasts, with the aid of local committees. Periodical inspections, quarterly exercise of crews, fixed rates of payments to coxswains and men, and quarterly reports were instituted, at the time when the self-righting self-empowering boat came into being. This boat was the result of a hundred-guinea prize, offered by the president, for the best model of a lifeboat, with another hundred to defray the cost of a boat built on the model chosen. In reply to the offer no fewer than two hundred and eighty models were sent in, not only from all parts of the United Kingdom, but from France, Germany, Holland, and the United States of America. The prize was gained by Mr James Beesling of Great Yarmouth, whose model, slightly modified by Mr Penke, one of the committee of inspection, became the foundation of the present boat, which, having been still further improved as time and experience have suggested, is now probably as near to perfection as can be attained.

The earliest year permitted to exhibit the progressive work of the institution is to contrast the report of 1860 with that of 1880. In the former year the receipts had dwindled down to £84 of subscriptions and donations, which, with £270 of dividends (on a capital of £9000) and a balance of £476 on hand, gave an available income of £350. The expenditure was £350, and the lives saved were about one hundred. In 1880 donations and annual subscriptions amounted to £28,240, dividends and interest (on a capital of £331,000) amounted to £9266. The total income was £38,506, besides legacies in the same year to the amount of £40,789. The expenditure, including liabilities, was £40,596, and the number of lives saved was about seven hundred. In the past twenty disastrous years (1861), the institution has saved 966 lives by its boats, and granted rewards for the saving of 156 more, besides rescuing 93 vessels from destruction. The total number of lives saved either by the lifeboats, or by special exertions for which the institution has granted rewards, since its formation, is 28,724, for which services 66 gold medals, 939 silver medals, and 209,000

in cash have been granted as rewards. So highly are the services of the institution appreciated that donations of boats, gifts of money, acknowledgments, and legacies come in from nearly all quarters of the globe, in sums varying from a shilling to £10,000.

Rocket Apparatus.—This, next to the lifeboat, is the most important and successful means by which shipwrecked persons are rescued on the British shores. Many vessels are cast every year on the rocky parts of the coasts, under cliffs, where no lifeboat could be of service. In such places the rocket alone is available. It is worked by the men of the coastguard, with the aid, in a few places, of volunteer rocket brigades. The courage and skill displayed in its use are evinced by the saving of many lives every year, and by the fact that a large proportion of the medals given by the lifeboat institution for heroic conduct are awarded to the men of the coastguard, who, besides managing the rockets, frequently man the lifeboats and also effect rescues in their own boats. The number of lives saved by means of the rocket apparatus in the year ending 30th June 1881 was 657. This, however, is the greatest number saved in any one year since 1856, at which date the life-saving rocket apparatus was placed under the entire control and management of the Board of Trade. The rocket stations on the coast at the 30th June 1881 numbered 288. The Board of Trade now gives a sum of money for each life saved, besides awarding silver and bronze medals for acts of special gallantry.

The apparatus consists of five principal parts, viz, the rocket, the rocket-line, the whip, the hawser, and the self-lubricating. The mode of working it is as follows: A rocket, having a light line attached to it, is fired over the wreck. By means of this line the wrecked crew haul out the whip, which is a double or endless line, rove through a block with a tail attached to it. The tail-block, having been detached from the rocket-line, is fastened to a mast, or other portion of the wreck, high above the water. By means of the whip the rescuers haul off the hawser, to which is hung the travelling or sliding lifeboat. When on the hawser the hawser has been fast to the mast, about 18 inches above the whip, and its other end is tacked fast to an anchor on shore, the lifeline is run out by the rescuers, and the shipwrecked persons, getting into it one at a time, are hauled ashore. Sometimes, in cases of urgency, the lifeboat is lowered by means of the whip alone, on which the system of the board with instructions to wrecked crews, printed in English and French, is sent off with the whip, as ignorance in regard to the mode of working the apparatus has been the cause of much loss of life. Such ignorance is culpable, because the Board of Trade issues enamelled plates with instructions, which are supplied gratuitously to shipowners and masters to be placed on conspicuous parts of their vessels, and are fixed in public places along the British coast, while every certificated officer in the mercantile marine is required to understand the working of the rocket apparatus.

The late Captain G. W. Mauley, F.R.S., in 1807 invented, or at least introduced, the mortar apparatus, on which the system of the rocket apparatus is founded. Previously, however, in 1791, the idea of throwing a rope from a wreck to the shore by means of a shell from a mortar had occurred to Sergeant Bell of the Royal Artillery, and about the same time, to a Frenchman named La Fere. Both of whom made successful experiments with their apparatus. In the same year (1807) a rocket was proposed by Mr Trengrove of Helston in Cornwall, also a hand and lead line as means of communicating with vessels in distress. The *heaving-cable*, a fruit of the latter suggestion, is now used at every station in the kingdom. In 1814 forty-five mortar stations were established, and Mauley reserved £2000, also addition to previous grants, in acknowledgment of the good service rendered by his invention. Mr John Dennett of Newport, Isle of Wight, introduced the rocket, which was afterwards extensively used. In 1826 four places in the Isle of Wight were supplied with Dennett's rockets, but it was not till after Government had taken the apparatus under its own control, in 1836, that the rocket now in use was adopted. It was invented by Colonel Boxer, and its peculiar characteristic lies in the combination of two rockets in one case, one being a continuation of the other, so that, after the first compartment has carried the machine to its full elevation, the second gives it an additional impulse, whereby a great increase of range is obtained. The rocket has now entirely superseded the mortar in England.

The *United States Life-Saving Service* is chief among the lifeboat societies of other nations, both as regards the extent of coast embraced and the amount of work done. There are several points of difference between this service and that of England which are noteworthy. In the first place the whole or nearly the whole of its

support is provided for by annual grants of money from Congress. Secondly, besides protecting its vast extent of seaboard, it is to provide for the shores of its great lakes, or fresh-water seas. Then, the coasts of America, unlike those of England, are destitute of human habitations in many places, which renders necessary the constant employment of sailmen for the express purpose of looking out for vessels in distress and manning the surf-boats. It also necessitates the erection of houses of refuge, procured so as to afford shelter and food to shipwrecked crews for a considerable time, at places where, without such provision, those who escape the sea would probably perish from hunger and exposure.

The shores of the United States—lakes and sea—are over 10,000 miles in extent, embracing almost every variety of climate and formation of land. This vast extent of coast-line is divided into 12 districts, with a total of 279 stations. Of these 139 are on the Atlantic, 34 on the lakes, and 6 on the Pacific. Those on the desolate coast of Florida are houses of refuge only, without boats or apparatus. Many of the stations are closed during the fine months of the year, then crews being disbanded till the winter gales again summon them to the heroic and dangerous work of saving the shipwrecked. That they render noble service in this way may be gathered from the annual reports. The report for 1830 shows that the distresses to shipping in that year amounted to 300; that on board of the vessels thus endangered there were 1989 persons, of whom 1980 were saved and only 9 lost. The property imperilled at the same time was estimated at, in round numbers, \$760,000, of which over \$640,000 worth was saved, besides which, in one hundred and twenty-eight instances, stranded vessels were hove off, and piloted out of danger by the surfmen. The total number of lives saved by this service, since the introduction of the present system in 1871, to the close of the fiscal year in June 1881, was 11,864, the total number of persons sheltered 2610, and the number of days shelter afforded 7350, the total value of property saved, \$14,958,875.

Owing to the flat shores of the Atlantic coast, and the sparseness of the population, heavy boats are found unsuitable. Only a few boats on the English model exist in the service. The boats chiefly in use are surf-boats, incapable of sea-sighting, and liable to be swamped, but which nevertheless serve well suited for the work, and are admirably managed. They are very light, and can, on their transporting carriages, be easily dragged along the shore by their crews. The cork life-belts worn by the men are of the plan first designed in 1854 by Rear-Admiral Ward. For projecting a line over a stranded vessel, the men use the mortar, or other piece of ordnance, to the rocket. In addition to the travelling life-buoys, they use a mattress car, or small covered boat, which can hold three or four persons, who, entering it by a small manhole, are slung in and drawn ashore, safely protected from injury, even though overboarded by the surf. Thus also, contrivances have been of great service in rescuing invalids, children, and aged persons. The total cost of the service is somewhere about £200,000 a year.

The history of the United States Life-Saving Service may be said to have begun in 1848, though half a century before that the Humane Society of Massachusetts had erected some huts of shelter and stationed some boats on the coast. In that year the United States Government was led to consider the subject of loss on their shores, chiefly through the energy of the Hon. W. A. Newell of New Jersey, a member of the House of Representatives. Captain Douglass Ottinger (the inventor of the life-buoy) was charged with the management and reconstruction of the service. The impetus given to it at this time was never quite lost. Again, in 1854, renewed efforts were made to improve the service, but no great progress was made till the year 1871, when the present effective system was organized, new stations were built; the patrol system between the stations was introduced; the regular keeping of journals and sending in of reports was ordered; libraries for the use of the men were sent to stations, uniformity in signals was arranged, and a thorough reform in all departments accomplished.

The French Society for Saving Life from Shipwreck, modelled on the basis of the English system, is a vigorous and highly efficient. It continues steadily to extend its operations along the coasts of France, besides introducing its life-saving apparatus into Algeria and other colonies. It was founded in the year 1865, and from that year onward has continued to do good and ever-increasing service in the saving of life from shipwreck. As the date of its report ending 30th June 1881, its lifeboat stations numbered 69, and its mortar or other projectile stations 391. During the year its life-boats and gun apparatus had saved 200 lives and 16 ships, to which may be added 81 lives, for the saving of which the society had granted rewards. From the time of its commencement in 1865 to the above date it has rendered the following noble service:—

Lives saved by its own boats and apparatus	1,826
Lives saved by other means, for which the society granted rewards in gold, silver, and bronze medals, and cash	308

Total of lives saved from the beginning 2,129

Besides this it has saved 146 vessels and succoured 546, and has awarded 28 gold, 120 silver, and 316 bronze medals, 1313 diplomas d'honneur, and about £20,400 in recompenses to those who have assisted in saving life in circumstances of unusual danger. It has also spent about £53,000 in the purchase and repair of its matériel. The reports of the society show that its work is appreciated. At 31st December 1880 the subscriptions and donations together amounted to nearly £2260, and the legacies bequeathed to it the same year were about £1000. The boats chiefly made are built on the model of those of the English institution. The gun is adapted to the rocket in connexion with the life-saving apparatus. In addition to its direct work of saving life, the French society has accomplished much good indirectly by its influence. It has been instrumental in bringing about this result, that, among the qualifications for a captain's certificate in the French mercantile marine, a thorough knowledge in detail of the means of saving life from shipwreck is required. It has also laboured to extend the usefulness and reduce the cost of the gun and rocket apparatus, besides securing that this apparatus, on Mr. Delvigne's system, shall be supplied to every ship of the French navy.

The German Association for the Rescue of Life from Shipwreck, under the patronage of the emperor William, was founded at Kiel in May 1850, and is a prosperous body in regard to its work and funds. It is maintained by voluntary contributions, and has 21 local branches on the coast and 27 in the interior, besides 140 agencies over the country. Previous to 1865 several private societies for saving life from shipwreck existed in the chief seaports of the North and Baltic. These have been absorbed in the present association, the proceedings of which are reported in a paper entitled *From Shore and Sea*, published at Bremen once a quarter, and largely modelled on the *Lifeboat Journal* of the English institution. The association provides the whole extent of the German coast with life-saving apparatus. It has 74 lifeboat stations, 30 of which are provided with the mortar or rocket apparatus. With these means it has, in the year 1880-81, saved 132 lives and 2 ships. The total number of human lives saved by the association since its commencement in 1854. From May 1860 to May 1881 the amount subscribed by its members was £257,300. As in America, the heavy self-righting and self-comprising life-boats have been found to be unsuitable to the thinly peopled and flat sandy beaches of Germany. Lighter and shallower boats have therefore been adopted. These are non-plated and not self-righting, but almost impossible to capsize. The stations are visited at least once a year by an inspector, and the whole system seems to be well regulated and thoroughly efficient.

In addition to the above, lifeboat societies or other lifeboat organizations—formed more or less on the basis of the Netcolt Lifeboat Institution of Great Britain—are to be found in Russia, Italy, and Spain.

Life-saving Hammocks, &c.—Various forms of buoyant mattresses, pillows, and india-rubber cloth life jackets and belts have been contrived. Among these may be specially mentioned the air lifeboat of Admiral Ward, which has four compartments, separately inflated, so that the puncture of one does not quite destroy the belt. Admiral Ryder's hammock also deserves notice. Its virtue lies simply in a cork mattress, which, when rolled up in its hammock, forms an efficient lifebuoy capable of supporting a man with his head and shoulders well above water, and it enables three men to float in an upright position. Cork mattresses are said to be cheaper and more comfortable than those stuffed with hair. Two such hammocks lashed together, about 26 inches apart, will enable two or three men to propel themselves easily through the water. The advantage of having such mattresses in a ship is obvious, for every one on board would be thus provided with a life-preserver.

It has also been suggested that the cushions of dock and cabin seats should, in a similar way, be made life-preservers, and that cabin furniture should be constructed so as to form rafts in cases of emergency. It is well to know, on the authority of the *Philosophical Magazine* (vol. xc. p. 369), that even a hat in a pocket handkerchief and hat in the crown downwards may be used to sustain a drowning man. It need scarcely be added that empty water-cans, tightly bunged, with ropes arranged for clinging to, form pretty good life-preservers.

(R. M. B.)

LIFTS may properly be held to include all sorts of apparatus whose object is the lifting of weights. When the apparatus consists of comparatively small, separate, and portable pieces, it is called *lifting tackle*. When the lifting apparatus reaches that degree of size and complication that entitles it to be called *machinery*, there seems to be no general technical term that will include all kinds, but for the different classes of lifting machines there are such special names as *cranes*, *hoists*, *elevators*, *lifts*, *winding engines*, and *lift pumps*.

There is very little distinction made between hoists,

elevators, and lifts. The word *hoist* refers more particularly to machines used in warehouses and factories for raising goods from one story to another. They are worked by hand or by power, and are for comparatively light loads. *Elevator* is used in two different senses. It refers to apparatus for lifting passengers to the upper stories of buildings. It also refers to the very different sort of apparatus used in grain-mills and storehouses for transferring the grain from one floor to another. The grain is drawn along channels or pipes, which are sometimes vertical and more often inclined, by means of a rotating archimedean screw, or of a strap continuously travelling upwards through the interior of the channel and carrying, fastened to it, a series of small buckets. Occasionally, if the inclination to the horizontal be small, a broad strap of the same width as the bottom of the channel runs along that bottom, and carries the grain with it simply lying on its upper surface. This latter method of transportation is more efficient, however, as a horizontal carrier or distributor than as a means of lifting. Grain might also easily be blown up a pipe by an air-blast, but the writer does not know any instances of this method having been used. *Lifts* are constructed either for raising passengers in buildings or for heavier loads, such as freighted trucks and waggons, or the superstructure of bridges and large roofs during their erection.

In lifts or elevators, the working force is either hand, steam, or hydraulic power. Gas-engines are unsuitable as direct sources of power for lifts, but they may be advantageously used to store hydraulic power in an accumulator from which water is supplied to work an hydraulic lift. Electricity has quite recently been used, but has not yet been tried sufficiently to allow of any valuable opinion being formed of its ultimate practical success.

The lift consists of (1) a box or "cage" to contain the persons or material to be raised, (2) a vertical square well or shaft, to the walls of which are attached guides to prevent the cage swinging to and fro; (3) a rope or chain by which to haul the cage upwards from above, or else a long rod or pillar by which to push it up from below, (4) a "barrel" or "sheave" over which to wind the chain or rope, and which is mounted on a shaft lying in bearings firmly supported by the building, or else a cylinder to contain water or steam to actuate the lifting rod; (5) mechanism through which the working power is transmitted to the barrel, or else water or steam piping connecting the cylinder above mentioned with the source of power; and (6) the driving engine or other source of power.

Most accidents happen to lifts through the hauling chain or rope breaking. For the sake of safety, therefore, particular care should be exercised in the choice of material for this part, and an appliance should always be attached to the cage whereby, if the rope breaks, the cage is caught immediately in whatever position it may be at the time of the breakage.

For light loads hempen ropes are sufficient and more convenient than chains, because they are noiseless in their action. If of the best quality (Manila) they are quite as reliable as ordinary chains, and an advantage claimed for them is that their gradual destruction by wear becomes easily apparent, and gives timely warning before they become dangerous, whereas the failure of a chain may take place without any easily visible previous sign having been given. For very heavy loads, however, chains or wire ropes should be used in preference to hempen ropes. Wire ropes may be made stronger for a given weight per foot of length than chains are, but unfortunately as commonly manufactured their quality cannot be certainly relied on. Like hempen ropes, they are almost noiseless.

To insure smoothness and noiselessness in passenger lifts, the sheave over which the rope passes is lined in the groove with leather.

For the sake of safety, the rope by which the cage hangs is often duple. Sometimes even three or four are used. In order that these should give additional safety, each rope must be capable of supporting the load by itself. Generally the load is lifted by one or other kind of power, and descends by the weight of the cage itself. This weight is always much more than sufficient for the purpose, and therefore counterpoises are introduced to balance the greater part of it, thus lessening the work to be done during ascent by an amount equal to the product of the balance weight and the height of the lift. In the commonest arrangement, the balance weights are hung on the same rope as that by which the cage is suspended. This passes over a pulley whose diameter is half the width of the well, so that the cage end of the rope rises vertically from the centre of the roof of the cage. This pulley is keyed on a horizontal shaft, which is driven by power from below, either directly by means of a rope or chain passing over another pulley, or else through intermediate spur gearing. The actual working rope is in this case not attached to the cage. Less frequently the rope from the engine forms one of the suspenders of the cage, the balance weights being attached by separate ropes.

The rope or chain by which the load hangs has to be so strong that its own weight is very considerable. A large excess of strength being more in demand in this kind of machinery than in other kinds, a greater stress than about 1 ton per square inch cannot be put upon the chain or rope (supposed to be of iron). This would make the rope weigh 3·4 lb per foot of length for every ton of load carried. If the height of lift were, for example, 60 feet, then, comparing the top and bottom positions of the cage, there would be in the former 60 feet less of rope on the cage side of the pulley, and 60 feet more on the counterpoise side, than in the latter position, so that if the counter-weight just balanced the load when the cage was at the bottom, it, along with the rope, would outweigh the cage in its highest position by the weight of 120 feet of rope, that is 408 lb for every ton of load, or nearly $\frac{1}{4}$ th of the whole load. Since the whole load—that is, that of cage, ropes, and passengers or goods—is three or four and sometimes five or six times as great as the net load, this is a very serious increase on the *unavoidable* loss of balance resulting from the fact that the cage is alternately loaded and unloaded. The difficulty can be got over by extending the rope downwards from the balance weight to pass underneath a grooved pulley at the bottom of the well, and up from this to the under side of the cage, where it is attached. There will then be an equal length of rope always hanging on each side of the top bearing pulley; but an extra amount of friction occurs at the bearing journals due to the weight of the extra rope. The lower half of the rope may be of cheap inferior material, since there is very little stress upon it.

A precisely similar difficulty occurs if the cage be lifted from below by an hydraulic ram or piston-rod. Occasionally the weight of the cage and ram is left unbalanced. In this case the water pressure on the ram or piston has to support the whole load. Suppose the pressure in the reservoir from which the water is drawn to remain steady during the ascent, then evidently at the top of its stroke the water pressure on the ram is less than at the bottom of its stroke, by the weight of a column of water of section equal to that of the ram, and height equal to the lift. Suppose, for example, that the water pressure at the level of the face of the ram in its highest position is 200 lb per square inch. Then for every ton of total load there must be provided about 11 square inches of piston area. A column of water of this horizontal section and 1 foot high weighs about 4·75 lb. This would give a difference of supporting pressure of 285 lb for every ton of total load in a lift of 60 feet, that is, about $\frac{1}{4}$ th of the total load.

of the cage and the ram is balanced by counterpoises on chains fastened to the top of the cage and passing over a pulley overhead, while the water pressure is used to overcome only the friction, and the additional load of passengers or goods. In this case again, owing to the passage of the chains over the pulleys, the balance is disturbed in a rise of 50 feet, by about 1 lb the weight of the cage and the ram, while the upward water pressure on the ram is the same rise diminished by 4 lb. The former disturbance of balance is a *decrease* of the load resting on the base of the ram, while the latter is a *decrease* of the supporting pressure on the same base. If these were made equal, the cage and load would be perfectly balanced in every position. To make them equal, it would be necessary simply to adjust the ratio of the part of the load borne by the counterpoise to the part borne by the water. Let the former part be W_1 and the latter W_2 , the total load being $W_1 + W_2$. Then for a water pressure of 200 lb per square inch, it would be necessary to have

$$\frac{1}{2}W_1 = \frac{1}{2}W_2, \text{ or } W_1 = \frac{1}{2}W_2 = \frac{1}{2}(W_1 + W_2)$$

For a pressure of 400 lb per square inch, the equation would be

$$W_1 = \frac{1}{4}W_2 = \frac{1}{4}(W_1 + W_2).$$

For 100 lb per square inch it would be

$$W_1 = \frac{1}{2}W_2 = \frac{1}{2}(W_1 + W_2).$$

Thus adjustment would necessitate a large unnecessary consumption of water, because the weight of cage and ram always bears a much greater ratio to the extra weight of passengers or goods than any of the above fractions $\frac{1}{2}$, $\frac{1}{4}$, or even $\frac{1}{2}$. The adjustment being attainable by other means, this waste can in no case be desirable.

If a second cylinder stand beside the lift-well and be connected by a pipe to the cylinder directly underneath the cage, so that there is a continually open passage between the two cylinders, then the supporting rod underneath the cage, together with the column of water leading from its base through the pipe to the second cylinder, is the exact counterpart in compression of the overhead ropes in tension in the other class of machine, and, as counterweights are hung upon these ropes, a balancing weight may be laid on the top face of the water in the second cylinder.

The balance weight, equaling that of cage and ram, rests on a plunger or piston fitting this cylinder, and the rod is extended upwards into a third smaller cylinder, on the plunger of which is admitted, by means of the valve worked from the cage or landing-platforms, an extra amount of water pressure suf-

Fig. 1.

Fig. 2.

ficient to elevate the extra load of passengers or goods. This is the arrangement in Tamm's hydraulic balanced lift. The for example, the ratio of the rope in the overhead arrangement passes from one cylinder to the other, and

never, in the same way as the rope passes from the cage side to the counterweight side of the overhead pulley. This is the lift used, which may be made correct for one position of the lift, becomes disturbed for other positions by a similar amount to that already unbalanced. A perfect balance of the constant part of the total load, namely, that of the cage and ram, is, however, obtained for all positions of the cage by the arrangement shown in figs. 1 and 2. This is the design of Mr. Edward Ellington, described by him in a paper read before the Institution of Mechanical Engineers in January 1882. The whole load is borne by the rod a underneath the cage, which enters as a ram into the vertical cylinder A . This rod is made solid in order to reduce the area of the cylinder as much as possible, and, therefore, also the area of the well that has to be bored in the ground to contain this cylinder. This class of lifts is especially expensive on account of this boring, and the objection to them on the score of expense is lessened by making the well small. The rod is made only just strong enough to safely bear the load on it. Its section should be designed with reference to the length of lift, because the longer the free length of the supporting pillar the greater is its tendency to buckle under a given load. If l be the stress per square inch calculated to be admissible on its section, and if W be the weight of cage and ram together and W' that of passengers or goods to be raised, the section is made equal to $\frac{W+W'}{l}$. Since

this same load has to be supported by the water pressure on the lower end of this rod, that water pressure is made also equal to h . This cylinder A is kept always in open communication with the lower end of the cylinder B . In this moves a piston b fastened to the top of the thick piston rod d . This passes downwards into the third cylinder C , and to its lower extremity is fastened the long piston e . These pistons have a common stroke, which is much shorter than the lift of the cage. The cylinders are correspondingly shorter than A , and they stand above ground. The ratio of the strokes may range from $\frac{1}{2}$ to $\frac{3}{4}$, and is the same as the ratio of the annular area of the under side of the piston b to that of the rod a . If b and d be the areas of the piston and piston rod, and c that of the rod supporting the cage, the ratio of the strokes is $b-d : c$. Suppose the piston b to be at the top of its stroke and the cage to be consequently at the bottom of the lift-well, then, if in this position the piston b be at a height above the lower end of A equal to h inches, and if w be the weight of a cubic inch of water, then, the pressure per square inch on a being h , that on the lower side of piston b is $h-hw$. The whole upward pressure on this piston is therefore $(b-hw)(b-d)$, and a downward pressure equal to or rather more than this must be exerted on the top of the rod a to lift the cage. This is supplied by admitting the water from the main, or from the hydraulic accumulator if force-pumps are employed to provide water-pressure, into the upper ends of the cylinders B and C . The lower end of C is always kept in open communication with the atmosphere. The water is continually admitted to B , and the water pressure on the top surface of piston b is designed to balance the constant load of cage and ram when this piston is at the top of its stroke. During the ascent of the cage, the water is admitted into C by a valve moved from the cage or platforms by means of the rope f , and the water pressure on the annular top surface of piston c , when that piston is at its highest position, is designed to balance the extra load of passengers or goods. During the descent, the cage being empty, the connection between C and the accumulator is shut by the valve actuated from the cage, and the water is allowed to escape freely to the atmosphere. If the pressure on c becomes equal to atmospheric pressure, it is the pressure per square inch of the working water at the level of the piston b at its highest position, and c be the area of the cross-section of cylinder C , and if h' be the length of plunger e , then in this position the whole downward force that is borne by the water is underneath the piston b , and distributed over its area to b , and $ph + (p + h'w)(c-d)$, when the pressure is on piston c , and simply ph when this pressure is cut off from C (To this should be added the weight of b , d , and c , but for our present purpose of explanation only this may be left out of account.) The former quantity has to equal $(b-hw)(b-d)$, and the latter should equal

$$\frac{W}{b-hw} - h'w(c-d).$$

These two equations serve to determine two of the quantities involved in terms of the other.

When the water pressure is admitted to the upper side of b alone, the intensity of pressure on the under side of b is evidently as many times greater than the intensity on its upper side as the area of its upper side is greater than that of its lower surface. Thus any increase of intensity on the upper surface will cause a correspondingly greater increase of intensity on the lower. Now if the pressure on the under side of b were to remain the same while the cage ascended, the pressure on the lower end of a would decrease by an amount proportional to the change in their difference of level. If, for example, the ratio of the strokes $b-d : c$ is $3 : 1$, then, as the cage rises 6 inches, b will fall 1 inch, and h , the difference of level

between b and a , will be decreased 7 inches. The pressure per square inch on a would decrease 7 psi, that on the under side of b kept constant. But, as the upper side of b also sinks 1 inch, the pressure per square inch on it will increase by 7. It now the ratio of this upper force of b to its lower area be made T , this increase of pressure on the top face will cause an increase of 7 psi on the lower face, and this just offsets the diminution of pressure on a due to the column 1 inch of the edge and fall of the lower side of b . Thus the imbedded edge will be in perfect balance, at whatever height it stands, if the areas b and $b-d$ are given the ratio

$$\frac{b}{b-d} = \frac{b-d}{a} + 1$$

The ratio $b-d$ of the two strokes having been already chosen, this equation gives b directly. From the other two equations c and the necessary pressure p are found. This pressure p may be obtained by hydraulic pumps, and an amount not loaded to the right amount. If, however, the water from the mains is to be used, the ratio of the strokes on the side of a may be modified so as to suit the available working pressure p . If p be proportional for the extra load at a given height, it will not be correct for all other heights, but this is not highly consequential, because the extra load itself is vanishingly small, so that no adjustment of d except of its maximum desired amount is possible. An excess of pressure on c above that needed for any given load has the effect simply of accelerating the speed of descent, and this is modified roughly by partially closing the valve admitting water to c .

We have shown this lift for description as the latest improvement in the design of hydraulic lifts. In it no water is wasted in raising or lowering the constant load.

When the hydraulic power is applied to the cage through a chain of rope passing over an overhead pulley, the hydraulic cylinder is usually laid horizontal for facility of setting and examination. Of course this arrangement involves much greater frictional resistance to the motion of the apparatus, but in it all the severely stressed parts may be in tension. There is an security when they are so than when they are in compression. Tange Brothers' hydraulic lift is an example of this.

Accidents to lifts occur in two ways. First, the suspending chain or rope may break, or, in those supported from below, the run may break, at the cylinder or in pipes enclosing the water way. To lessen the risk of such mishaps the only method is to insist on good design in the details, good materials (which should be subjected to test before being used) and good workmanship. The connection at both ends of the rope or chain to the load suspended from it, or the joining of the different sections of the run to each other and to the cage, is a point especially important. If such a breakage does actually occur, however, the cage is usually kept from falling by a device known as a toothed rack.

The connection at both ends of the rope or chain to the load suspended from it, or the joining of the different sections of the run to each other and to the cage, is a point especially important. If such a breakage does actually occur, however, the cage is usually kept from falling by a device known as a toothed rack. Tange Brothers have for this purpose at each corner of the cage a toothed rack. The suspending rope sustains the cage through levers as shown in fig. 5. So long as there is a considerable pull on the rope, the levers keep the cams in the position shown. If the strain on the rope is relieved by accident to its powerful spiral springs immediately the cams swing outwards and the rack becomes buried in the wooden guide-posts. A toothed rack is sometimes bolted to the vertical posts and tooth-shaped plungers are forced forward by springs to engage with the rack when the rope breaks. Similar arrangements are not placed between the top of the cage and the cage of direct acting hydraulic lifts, but it is a mistaken idea that they are not as necessary in this case as in the other. Such appliances should be examined and tested at regular frequent intervals. They are apt to get out of working order though durable. A double rope is a greater safeguard against accident.

In chain or rope lifts the gearing or other machinery may break, and in consequence the cage might run down with dangerous rapidity without the rope either breaking, or being wholly relieved of tension, so that the above catches may not come into action. This may be prevented by a self-acting clutch on the shaft, which prevents the barrel rotating unless the clutch is specially released. The most perfect and mechanically beautiful of the many devices that have been invented for this purpose is Weston's frictional automatic coupling. Fig. 4 shows it as applied to a hand shaft-hoist. To the shaft a is keyed a ratchet wheel b . A pawl gearwork this prevents the shaft from ever rotating except in one direction. The plate c is also keyed to the shaft. The leading rope sheave d and the winding barrel e both run loose on the shaft. Their opposing end surfaces are cut helically, so that, according to the relative angular positions of d and e , they are either jammed against each other and between c and b , or are loose and free to rotate round the shaft. On pulling the sheave d in one direction all the parts are frictionally

coupled together, and the barrel hauls up the load. The axial pressure producing friction between c and b and between d and e is greater than the load being hauled up in the ratio of the circumference of the barrel to the pitch of the helix. As there are two frictional surfaces, the whole friction is double this axial thrust multiplied by the coefficient of friction, and this friction must act at such a mean radius from the shaft as to balance the load on the shaft as to horizontal pressure.

If this is so for one load, it is so also for all others, as the friction is proportional to the load. To get sufficient friction for heavy loads with a diminished axial thrust, the very ingenious design shown in fig. 5 is adopted. Here the shaft a is driven by power, and is keyed to the boss d with a helix cut on one end. This helix abuts against a similar helix on the pumion e , which drives the hoisting barrel on a second shaft. The ratchet wheel b abuts against the collar f on the shaft a , b runs loose on the shaft and is cast on the end of a hollow drum containing three disks of hard wood, P, P, P. These disks contact with f along the interior of the drum, but are prevented from turning except along with the drum. The interlocking between these wood disks are two iron disks, O, O, which may slide axially along the boss of the pumion e , but are prevented from rotating except along with this pumion. The axial pressure is transmitted through the surfaces of the disks P and O, and, these being six pairs of surfaces between which this pressure is exerted, a very slight axial thrust produces sufficient friction at these surfaces to couple the ratchet wheel b to the pumion e . So long as this is exerted all the parts are jammed together, and the pawl engaging in b prevents the load lowering. When, however, the shaft a is rotated backwards, the helices disengage and the friction no longer binds e with b , so that e along with d and a can be rotated backwards and the load thus lowered. The weight of the load keeps e following d closely in its backward motion, and as soon as the operation of machine ceases to turn the shaft backwards the whole arrangement becomes once more frictionally bound together, and the ratchet wheel prevents further lowering. Fig. 6 shows another arrangement whereby the pumion e is unaccepted and allowed to lower the load by only a slight backward motion of the shaft a , it being unnecessary to rotate the shaft back and continuously.

This last is obviously the most handy arrangement, and when worked carefully is as absolutely safe as the other. This device in a modified form is used in Tange's lifts.

Thomas & Sons, of Cardiff, have a similar patent safety shaft coupling, which, although it has a very different form, is constructed on exactly the same principle as that of fig. 5.

Steam has been used as a motive power in long cylinders similar to those in hydraulic lifts. It has the great advantage of being very little weight, so that the difference of head occasioned by the rise of the piston is practically nil. The disadvantage is that the steam rapidly condenses, and thus the load could not be held up at any desired height for a length of time, without a continual fresh supply of steam to the cylinders. It is not likely to come into general use for passenger lifts, but may be used advantageously for goods lifts and heavy cranes.

LIGHT

SOUND may be defined as any effect on the sense of hearing, and in the same way **Light** may be defined as any effect on the sense of sight. This is the purely subjective use of the terms. But both terms are quite as frequently used in the objective as in the subjective sense. Thus, as **Sound** may be defined in terms of the motion of the air in the cavity of the external ear, mechanically affecting the tympanum, so **Light** may be defined by the mechanical effect produced upon the extension of the optic nerve which forms the sensitive surface of the retina.

In treating of **Light** it will be convenient to use the term in a sort of mixed sense, at least until we come to discuss the different theories which have been devised to account for the propagation of the agent which causes vision. Then we shall have to use the term entirely in the objective sense. On the other hand, in Physiological Optics we are concerned chiefly with the subjective sense of the term.

The present article is intended to give a general sketch of the subject of Optics, so far as it can be treated by the help of elementary mathematics, but with sufficient detail to show the connexion of its various branches, and to enable the reader who desires further information on any point to judge for himself under what heading he will find it in this work. The subject is arranged in the following order:—

Early History of Optics
Preliminary Statements with regard to Vision, Distinct Visions, the Colour-Sense, and the Duration of Visual Impressions
Sources of Light
General Reflections on the Mechanism of Propagation of Light
Division of the Subject into Geometrical and Physical Optics.

GEOMETRICAL OPTICS.

Rectilinear Propagation of Light in Homogeneous Media, Shadows, Common Obscurity, &c.
Intensity of Illumination, as depending on the Distance of the Source and the Obliquity of the Rays. Brightness and Intrinsic Brightness
Photometry.
Velocity of Light.
Behaviour of Light at the Common Surface of Two Homogeneous Media.
Reflection. Plane, Spherical, and Cylindrical Mirrors. Real and Virtual Images.
Single Reflection. Composite Nature of White Light. Refractive Index. Dispersion. Prisms; Strahlender Lines. Irregularity of Dispersion. Achromatism. Lenses. Telescope, Microscope. Pure Spectrum. Refraction by Cylinder. Rainbow.
Refraction in a Non-homogeneous Medium. Hamilton's Characteristic Function. Mirage.
Absorption, Abnormal Dispersion, Fluorescence, Phosphorescence.

PHYSICAL OPTICS. UNDULATORY THEORY.

Nature and Propagation of Waves. Huygens's Principle. Explanation of Reflection and Single Refraction. Disproof of the Corpuscular Theory.
Sketch of the History of the Undulatory Theory. Young's Discovery of Interference.
Interference Bands. Spectrum formed by Gratings. Measure of Wave-Length. Loss of Semundulation. Newton's Rings. Colours of Thin Plates and of Grooved Surfaces.
Relation between Wave-Length and Refractive Index.
Double Refraction. Wave-Surface in Iceland Spar.
Polarization. Transverse Vibrations. Nature of Unpolarized Light.
Plane, Circularly, and Elliptically Polarized Light. Nicol's Prism. Depolarization by Doubly-Refracting Plate. Fresnel's Rhomb.
Doppler's Principle. Measurement of the Relative Velocity of Luminous Source and Spectator.

Under OPTICS (GEOMETRICAL, PHYSICAL, and PHYSIOLOGICAL) further developments will be given; and the

connexion between light and radiant heat will be discussed under **RADIATION**.

EARLY HISTORY OF THE SUBJECT—It is to sight that the we are mainly indebted for our knowledge of external things. All our other senses together, except under very special conditions, do not furnish us with a tithe of the information we gain by a single glance. And sight is also that one of our senses which we are able most effectively and extensively to aid by the help of proper apparatus—not merely (as by spectacles, invented circa 1300) for the cure of natural defects, but (as by the telescope and microscope) for the examination of bodies either too distant or too minute to be studied by the unaided eye.

It is very remarkable, under these circumstances, to find how slowly men have reached some even of the simplest facts of optics. We can easily understand how constant experience must have forced on them the conviction that light usually moves in straight lines,—i.e., that we see an object in the direction in which it really lies. But how they could have believed for ages that objects are rendered visible by something projected from the eye itself—so that the organ of sight was supposed to be analogous to the tentacula of insects, and sight itself a mere species of touch—is most puzzling. They seem not till about 350 B.C. to have even missed the question—If this is how we see, why cannot we see in the dark? or, more simply,—What is darkness? The former of these questions seems to have been first put by Aristotle.

The nature and laws of reflexion were, of course, forced on the ancients by the images seen in still water; and the geometrical of the Hæcetic school were well acquainted with these laws. To Hero of Alexandria we owe the important deduction from them that the course of a reflected ray is the shortest possible.

The general nature of refraction also was known, with some of its special applications, such as, for instance, to burning-glasses and to magnifiers. These were probably either spherical glass shells filled with water (Pliny, *H.N.*, xxxvi. 67 [25]; Lact., *De Ira Dei*, c. 10) or balls of rock crystal (Pliny, xxxvi. 10).

In the first century of our era Ptolemy pointed out how a coin at the bottom of an empty cup, where the eye cannot see it, can be made visible by filling the cup with water; and he showed that, in a similar way, the air may render the sun visible to us while it is still under the horizon. Shortly after this date Ptolemy (the celebrated astronomer) published his great work on Optics. He treats of vision, refraction, the theory of plane and concave mirrors, and refraction. He measured, with considerable accuracy, the angles of incidence and refraction, for rays passing from air into water and into glass, and from water into glass; it was not, however, till more than fifteen hundred years had passed that the true relation between these angles was discovered. In addition to what has just been mentioned, the ancients' knowledge of optics was limited to a very superficial acquaintance with some of the properties of rainbows, halos, mirage, &c. But it was fragmentary in the extreme—though it far surpassed in amount as well as in accuracy their knowledge of the other branches of physical science.

It is not easy to understand the ideas of the ancients about colour. That it is a property of a body—just as its density, its hardness, or its smell is a property—was probably held by them. But they also imagined that a body could communicate its colour to light; thus, for instance, the clouds were, by some of them, supposed

to communicate their colours to the sunbeams which form a rainbow.

Our next glimpse of real progress dates from the 11th or 12th century, when ALHAZEN (*q.v.*)¹ wrote a treatise on optics in Arabic, which for five hundred years or more was a recognized authority on the subject. It was, in many parts, founded on the work of Ptolemy, but with considerable additions and improvements. Alhazen gives an anatomical description of the eye, and points out, fairly enough, how with two eyes we see only one image. But he also points out that we see each object, however small, by a *penetral* of diverging rays,—not (as the ancients imagined) by a single ray. Alhazen accounts for twilight, and shows how by it to measure the height of the atmosphere. He also gives the now generally received explanation of the curious fact that the sun and moon appear larger when rising or setting than when they are high in the heavens.

The farther progress of the subject we need not now trace. From the end of 16th century that progress has been extremely rapid. The dates of the more important steps, and the names of their authors, will be given when we treat of these, in their turn, in the course of the article; and we will give them the additional interest of being presented, when this can readily be done, in the author's own words.

Vision.

PRELIMINARY STATEMENTS.—Before we commence a more rigorous treatment of the subject, it may be well to make a few preliminary statements as to the nature of vision and the conditions for distinct vision. Properly speaking, these belong to OPTICS (PHYSIOLOGICAL) (*q.v.*), but it is impossible to treat intelligibly any part of our subject without presupposing some, generally very slight, knowledge of other parts. And the few preliminary statements we have now to make are in no respect theoretical, while they are so simple that any one may at once test their truth for himself.

Distance of distinct vision.

Except in the case of a very abnormal eye (extremely short-sighted or long-sighted as the case may be) there is a distance from it—usually somewhere about 10 inches—at which if an object be placed it is seen more distinctly than if placed at any other distance. Almost every one, perhaps without knowing it, habitually places at or about that distance from his eye an object which he wishes to examine carefully. When he places it at a smaller distance he becomes conscious of the effort required to see it distinctly. He has, in fact, to alter the form of the optical machinery of the eye, by a muscular effort, so that it may become capable of bringing to a focus on the retina rays more divergent than those for which the parts were in their unstrained state adapted. A corresponding effort, but usually much more slight, is commonly felt to be required if the object be at a distance greater than 10 inches.

Limits of distinct vision.

Hence we arrive at the conclusion that, for the minimum of strain on the eye, rays should fall on it diverging as if they came from a point about 10 inches distant. But for all ordinary eyes any divergence from double of this (*i.e.*,

divergence as if from a distance of 5 inches) to zero (*i.e.*, parallel rays) is consistent with the possibility of distinct vision. Rays either more divergent than the former limit, or convergent, are unfit to produce distinct vision. Hence every optical instrument, whatever be the reflexions or refractions to which light has been subjected in passing through it, must finally allow the light to escape either in parallel rays or with a divergence within the above specified limits, if it is to be employed by an ordinary eye. The comparatively slight differences which exist among ordinary eyes are easily compensated by the rack-work, or screw adjustment, which is invariably attached to the eye-piece of a good telescope and to the body of a good microscope. Every motion of this rack-work alters the divergence of the rays as they finally escape from the instrument. Any eye, however abnormal, if it be capable of producing distinct vision at all, has only to be furnished with suitable spectacles in order that it may behave exactly as does a normal eye. The statement, however, refers only to sharpness of definition, not in any degree to colour. The deficiency which causes *colour-blindness* cannot be supplied by any conceivable process. A definite part of the ordinary organ of vision is wanting (or inactive) in such cases—while the merely optical parts of the eye are usually in perfect order.

Another fact which must be stated here is that, to produce vision of a body in its natural position, the image on the retina, as seen from the back, must be inverted—not merely as regards up and down, but also as regards right and left. Thus, in the ordinary astronomical telescope, the image on the retina is not inverted, and we therefore see an inverted image.

A third is that our judgment of the relative distances of objects is formed mainly by the use of the two eyes simultaneously. One eye, kept still, can inform us only of relative distance in virtue of the greater or less effort to see distinctly (already spoken of). With both eyes, or with one eye moved from side to side, *parallax* comes in, and gives us the *stereoscopic* effect, as it is called. This power of judging distance is, of course, greater as the eyes are set more widely apart. There is, practically, no limit to the effective distance between the eyes when the proper instrumental methods (as with the telescope) are employed.

It is also necessary to premise a few words about colour.

The various homogeneous rays of the solar spectrum have each a colour of its own which no refraction can modify. But what about the many colours which do not occur in the spectrum? To such a question as "What is yellow?" the answer is, "Each particular kind of yellow may be any one of an infinite number of different combinations of homogeneous rays." And the same is true, in general, of all other colours. Clerk Maxwell found that a yellow equivalent to that of the spectrum can be obtained by mixing in proper proportions certain homogeneous red and green rays. This single example is sufficient to show that the colour-sense is of a very singular nature. This question will be fully treated in OPTICS (PHYSIOLOGICAL); but for our present purpose it is only necessary to say that we now know (after Wüch and Young) that the normal eye has only three colour-sensations—a red, a green, and a violet,—and that the apparent colour of any light which falls on it depends merely on the relative intensities of the excitement produced by the light on the three organs of sense corresponding to these sensations. This is true, however, only within certain limits of intensity; for extremely bright light, whatever be its real colour, seems to excite all the three sensations simultaneously, much as white light does; and with very feeble light (as, for instance, that of an ordinary aurora or of a lunar rainbow) we are sometimes scarcely conscious of

¹ The proper name of this geometer is El-Hazan (or by other accounts Muhammad) bin al-Hazan bin al-Estheran, and it is as Ibn al-Estheran that he is commonly referred to. See Woepcke, *L'Algèbre d'Omar Alkhiyari* (Paris, 1851), p. 73 *sq.*, and Bar Hebraeus, *Chronica*, p. 221 *sq.* Several of his mathematical treatises exist in English libraries (see the Catalogues of the Br. Mus., Bodl., and India Office MSS.); but the only copy of his great optical work—the *Kitab al-Mandari*—known to be in Europe is No. 1011 of the Leyden collection, with the commentary *Sharh al-Mandari* of Kamil ed-Din Abul Hasan (Cat. Cod. Or. Leyd. Bat., III. 61). A smaller work (Woepcke, *op. cit.*) was based on the optical treatise ascribed to Alhazen and Ptolemy, and Ibn al-Estheran claims to have restored the lost first book of the latter. The Arabs had Alhazen's Optics (*Kitab al-Mandari*) in the version of Nasir ed-Din Tusi (*H. Khatt.*, No. 10,582; Loth, *MSS. of India Office*, No. 748).

Colour-blindness

colours. In *colour-blindness* one or more of these organs of sense is wanting, or imperfect. The most common form, Daltonism, depends on the absence of the red sense. Great additions to our knowledge of this subject, if only in confirmation of results already deduced from theory, have been obtained in the last few years by Holmgren¹; who has experimented on two persons, each of whom was found to have one colour-blind eye, the other being nearly normal. In this way was obtained, what could otherwise have been matter of conjecture only, a description of colour-blind vision in terms of (at least approximately) normal vision.

Duration of visual impressions

Finally, the sensation of sight is not limited to the duration of the mechanical action on the eye. It is known that we do not see a sudden flash (an electric spark for instance) until a measurable, though very short, period has elapsed. This depends on the rate at which an excitation is propagated along the optic nerve. But the familiar experiment of whirling a red hot stick in a dark room shows that the sensation of sight lasts for a short period after the mechanical action which produced it has ceased. This period is probably different for different eyes, and for different amounts of excitement even in the same eye. (If the light be very intense the effect lasts much longer, but completely changes its character.) For our present purpose it may be assumed that the duration is somewhere about $\frac{1}{4}$ th of a second. Thus, if the end of the red-hot stick describes a circle once in $\frac{1}{4}$ th of a second, we see the complete circle, if in a longer period, we only see at once such a part of it as was described in $\frac{1}{4}$ th of a second. Connected with this is the remarkable result obtained experimentally by Swan,² that the amount of sensation is, for flashes of short duration, directly proportional, not only to the brightness of the flash, but also to its duration. A flash which lasts for $\frac{1}{4}$ th of a second produces the full effect on the eye; but an electric spark, as a flash of lightning, which certainly does not endure for more than $\frac{1}{1000}$ th of a second, produces at most only $\frac{1}{1000}$ th of the effect it would produce if it lasted $\frac{1}{4}$ th of a second. On this short duration of visual impressions depends the action of the *chaumatrope*, the *wheel of life*, &c. By various kinds of machinery a succession of views of an object in different positions or forms is presented to the eye, each for a brief interval. The result is that we fancy we see one and the same object going through a species of *continuous* motion, or of change of form, which would present it to the eye in these successive positions or forms. Thus, a tadpole may be represented as wriggling about, or as developing continuously into a frog, &c.

Intensity as depending on duration of exciting cause.

SOURCES OF LIGHT.—This subject will be fully treated in other parts of this work under various heads: from the purely scientific point of view under **RADIATION**; from the more practical side under **LIGHTING** (**ΕΛΚΤΙΣΜΟΣ**), &c. For our present purpose a very brief summary of the question will suffice; and we do not require to investigate the *process* by which, in any case, the light is produced.

Incandescence

1. The main source of light is *incandescence*. (It is usually understood that to be *incandescent* a body must be at a high temperature.) This may be due to any of a number of causes, such as the following:—

(a) *The Potential Energy of Gravitation of Scattered Fragments of Matter.*—When these fall together, as in the formation of the sun and stars, heat enough is generated by impact to render the whole vividly incandescent. It is probable that the light of nebulae, and the *proper* light of comets, is due to this cause. The proximate causes in all these cases is the kinetic energy of the fragments

before impact. To this class, therefore, can be reduced the light given out when a target is struck by a cannon shot.

(b) *The Kinetic Energy of Current Electricity or of an Electric Discharge.*—Here we have lightning, the electric light, and probably also the light of the aurora.

(c) *The Potential Energy of Chemical Affinity.*—The lime-light, gas-light, candle and lamp-light, fire-light, the magnesium light, &c.; also phosphorus, dead fish (f), &c., glowing in the dark.

(d) *Friction*, as in the trains of sparks from a grindstone or brake; though here, in general, chemical affinity also has a share.

(e) *Sudden great Compression of a Gas*, as of air by meteoric stones and falling stars.

2. Another very curious source, not (so far as is known) reducible to incandescence, is the *giving out* (usually in excited or altered form) of light previously absorbed:—fluorescence, phosphorescence, &c.

3. A third source is *physiological*:—fire-flies, glow-worms, *Medusa*, dead fish (f), &c., the eye of a cat

Any not black and not transparent body, exposed to any of these sources of light, becomes in its turn what may for our purposes also be treated as a source.

As will be shown in **RADIATION**, the only bodies which, when incandescent, give *every* constituent of white light are bodies which are black in the sense of absorbing each and every ray which falls upon them. Such bodies are not necessarily solids—though the best examples we have of them are lamp-black, and (somewhat less perfect) charcoal and gas-coke.

Newton's speculations on these subjects, taken from the *Newtonian "Queries"* at the end of his *Optics*, give an exceedingly interesting sketch of the state of this subject in his time. We quote a few of the more curious. There is a strange admixture of errors, but a still more strange anticipation of some of the most important of modern discoveries.

"Query 6. Do not Black bodies conserve heat more easily from light than those of other colours do, by reason that the light falling on them is not reflected outwards but enters the bodies, and is often reflected and refracted within them, until it is stifled and lost?"

"Query 8. Do not all Fixed bodies, when heated beyond a certain degree, emit light and shade; and is not this emission performed by the vibrating motions of their Parts. And do not all bodies, which abound with Terrestrial parts, and especially with Sulphureous ones, emit light, as often as those Parts are sufficiently agitated; whether that agitation be made by heat, or by friction, or percussion, or putrefaction, or by any vital motion, or any other cause?"

"Query 9. Is not Fire a body heated so hot, as to emit light copiously? For what else is a red hot iron than fire? And what else is a burning coal than red hot wood?"

"Query 10. Is not Flame a vapour, fume, or exhalation heated red hot, that is, so hot as to shine? For bodies do not flame without emitting a copious fume, and this fume burns in the flame. The *Ignis Fatuus* is a vapour shining without heat, and is there not the same difference between the vapour and flame, as between rotted wood abating without heat and burning coals of fire? In distilling hot spirits, if the head of the still be taken off, the vapour, which ascends out of the still, will take fire at the flame of a candle, and turn into flame, and the flame will run along the vapour from the candle to the still. Some bodies heated by motion or fermentation, if the heat grow useless, fume copiously; and if the heat be great enough, the fumes will shine, and become flame. Metals in fusion do not flame for want of a copious fume, except spelter, which fumes copiously, and thereby flames. All flaming bodies, as oil, tallow, wax, wood, fossil coals, pitch, sulphur, by flaming waste and vanish into burning smoke; which smoke, if the flame be put out, is very thick and visible, and sometimes smells strongly, but in the flame loses its smell by burning; and, according to the nature of the smoke, the flame is of several colours; as that of sulphur, blue; that of copper, green with sublimis great; that of tallow, yellow; that of camphire, white. Smoke passing through flint cannot but grow red hot; and red hot smoke can have no other appearance than that of flame. . . .

"Query 11. Do not Great bodies conserve their heat the longest, their parts heating one another; and may not Great bodies and Fixed bodies, when heated beyond a certain degree, emit light?"

¹ *Proc. Roy. Soc.*, Jan. 1881.

² *Trans. Roy. Soc. Edin.*, 1849, 1861.

coquishly, as by the emission and re-action of its light, and the reflexions and refractions of its rays within its pores, to grow still hotter, till it comes to a certain period of heat, such as is that of the sun! And are not the sun and fixed stars great earths vehemently hot, whose heat is conserved by the greatness of the bodies, and the mutual action and re-action between them, and the light which they emit, and whose parts are kept from running away, not only by their fixity, but also by the vast weight and density of the atmospheres incumbent upon them, and very strongly compressing them, and containing the vapours and exhalations which arise from them! . . . And the same great weight may condense those vapours and exhalations, as soon as they shall at any time begin to ascend from the sun, and make them presently fall back again into him, and by that action increase his heat, much after the manner that in our earth the air increases the heat of a culinary fire. And the same weight may hinder the globe of the sun from being diminished, unless by the emission of light, and a very small quantity of vapours and exhalations."

THEORIES OF PROPAGATION OF LIGHT.—We may begin by assuming that the sensation of light is due to a mechanical action on the retina (see EYE). Now such a mechanical action must have a mechanical cause, and, as far as we can judge with our present knowledge, this latter must consist of impacts on the retina, due to moving matter. This matter may have travelled all the way from the source of light, or it may have been set in motion in the eye by a disturbance (analogous to a wave) which has travelled from the source. What is transferred, or what moves, is a quite independent question. Light must, as far as we can conceive, consist in the motion of particles of some kind from external objects to the eye, or in the propagation of some disturbance or wave-motion in an as yet unknown medium. Though it has been proved, as we will presently show, that some of the consequences of the first supposition are entirely inconsistent with observed facts, the nature of the propagation of the supposed luminous particles is still a very interesting study, and indeed many of the fundamental propositions in optics follow more easily from this hypothesis than from the other. We will therefore *not* at present dismiss this hypothesis, but will refer freely to it now and then, until its truth is shown to be inconsistent with experiment.

This view, associated with the names of Newton, Laplace, and Biot, is known as the *corpuscular theory* of light. A formidable objection to it, *in limine*, will be easily seen to be furnished by the velocity of light. Since every point of every visible body must (on this theory) send such corpuscles to the eye, moving as we shall find at a rate of nearly 200,000 miles per second, their masses must be inconceivably minute in order that their united momentum may not amount to something comparable with that of a cannon shot, a supposition of course utterly destructive of all belief in the hypothesis. But, as we shall see, there are still higher grounds of objection, and such as no mere smallness of mass or size of each corpuscle can explain away.

The rival theory labours under considerable disadvantages, inasmuch as the theory of wave-propagation is very much more obscure and difficult than that of the motion of free particles; but the student, who has mastered the fundamental difficulties of sound (see ACOUSTICS), which presents a fair although not an exact analogy, will find it comparatively easy to obtain a clear conception of the fundamental principles of the explanation offered by the *undulatory theory* of light.

The difference between these two theories of light may be illustrated by contrasting wind moving at the rate of 1100 feet per second (an inconceivably violent hurricane) and sound, gentle or violent, moving at precisely the same rate—yet how different in its effects!

DIVISION OF THE SUBJECT.—Optics, or the science of Light, is usually divided into two parts. A simple illustration of the nature of this division will be found in

the different conditions of fluid equilibrium according as Geom. we do not or do introduce the idea of action between metrical the fluid and the containing vessel (CAPILLARY ACTION, and physical optics g *). In the first or hypothetical case it is known that the free surface must be horizontal, and that all its separate parts must lie in the same plane, in the second, *i. e.*, the actual, case we find molecular action modifying these results, sometimes indeed to a very large extent, so that no part of the free surface is plane, and no two portions of it are at the same level. So in what is called GEOMETRICAL OPTICS it is assumed from experiment that light moves in straight lines in air, while PHYSICAL OPTICS, or the undulatory theory, agrees with experiment in showing that under certain circumstances a ray of light bends round an obstacle. But as, in obtaining the main facts of fluid equilibrium, capillary forces may be neglected, so, for the explanation of the ordinary phenomena of light, even with accuracy sufficient for the construction of the very finest telescopes and microscopes, it suffices that Geometrical Optics, based on laws *nearly* verified by experiment, be followed out to its consequences. The residual phenomena then came in to be treated by the undulatory theory. Foucault divides the subject, in consequence of this distinction, into two parts, *viz.*, (1) that in which we deal with the direction only of the rays, and (2) that in which we deal with the physical properties of the rays themselves.

In this order we will consider the subject, giving the Proposed explanations of the approximate experimental laws of *order of treatment* Geometrical Optics, as we reach them, in the language of either theory. But before we come to the residual phenomena we shall have found that the corpuscular theory must be rejected, and we will therefore give, without detail, the principles of the undulatory explanation, which will be fully discussed in a special article.

GEOMETRICAL OPTICS.

Rectilinear Propagation of Light.

It is approximately true that, in any homogeneous medium, *light moves in straight lines*.

If an opaque body be placed anywhere in the straight line between the eye and an object, the object is concealed. Through a long straight tube no objects can be seen but those situated in the direction of its axis produced. This is so fundamental a fact, or it is so evident a result of experience, that it is the foundation of every process which involves the direction in space of one object as regards another,—whether it be for the aiming with a rifle, the pointing of a telescope, or for the delicate observations of a geodetic survey. But we must carefully observe the restrictions under which the statement is made. Not merely is it said to be only approximately true, but it is so only in a homogeneous medium. To both of these restrictions we will revert later.

(a) On this is founded the geometrical theory of *shadows*, *Shadows*.

—a subject of some importance, especially as regards eclipses. In this application the results may be considered as absolutely true, though, as we shall see in a subsequent page, the statement is liable in certain delicate cases to somewhat startling exceptions. When an opaque body is placed between a screen and a luminous point, it casts a shadow on the screen. (The sun's image formed by a lens or burning glass of short focus is our best mode of attempting to realize the conception of a luminous point; but a fair approximation may be made by piercing a very small needle-hole in a large plate of thin metal, and placing it close to any bright flame or incandescent body.) The outline of the shadow is, of course, to be found by drawing straight lines from the luminous point so as to touch the

theory.

Undula-
tory
theory.

opaque body all round. These lines form a cone. The points of contact form a line on the opaque body separating the illuminated from the non-illuminated portion of its surface. Similarly, when these lines are produced to meet the screen, their points of intersection with it form a line which separates the illuminated from the non-illuminated parts of the screen.

This line is called the boundary of the *geometrical shadow*. A common but beautiful instance of it is seen when a very small gas-jet is burning in a ground-glass shade, near the wall of a room. In this case the cone, above mentioned, is usually a right cone with its axis vertical. Thus the boundary of the geometrical shadow is a portion of a circle on the roof, but a portion of an hyperbola on the vertical wall. If the roof be not horizontal, we may obtain in this way any form of conic section. Interesting and useful hints in *perspective* may be obtained by observing the shadows of bodies of various forms cast in this way by rays which virtually diverge from one point *e.g.*, how to place a plane quadrilateral of given form so that its geometrical shadow may be a square, how to place an elliptic disk, with a small hole in it, so that the shadow may be circular with a bright spot at its centre, &c.

When there are more luminous points than one, we have only to draw separately the geometrical shadows due to each of the sources, and then superpose them. A new consideration now comes in. There will be, in general, portions of all the separate geometrical shadows which overlap one another in some particular regions of the screen. In such regions we still have full shadow, but around them there will be other regions, some illuminated by one of the sources alone, some by two, &c., until finally we come to the parts of the screen which are illuminated directly by all the sources. There will evidently be still a definite boundary of the parts wholly unilluminated, *i.e.*, the true shadow or *umbra*, and also a definite boundary of the parts wholly illuminated. The region between these boundaries—*i.e.*, the partially illuminated portion—is called the *penumbra*.

Fig. 1 shows these things very well. It represents the shadow of a circular disk cast by four equal luminous

Fig. 1.

points arranged as the corners of a square,—the disk being large enough to admit of a free overlapping of the separate shadows. The amount of want of illumination in each portion of the penumbra is roughly indicated by the shading. The separate shadows are circular, if the disk is parallel to the screen. If we suppose the number of sources to increase indefinitely, so as finally to give the appearance of a luminous surface as the source of light, it

is obvious that the degrees of darkness at different portions of the penumbra will also increase indefinitely, *i.e.*, there will be a gradual increase of brightness in the penumbra from total darkness at the edge next the geometrical shadow to full illumination at the outer edge. It is most instructive to contrast with the above figure that now given (Fig. 2), in which the size of the disk is considerably diminished—everything else being unchanged. Here there is no true shadow—only four *equally bright* portions of the penumbra, each illuminated by three of the sources.

Fig. 2.

Thus we see at once why the shadows cast by the sun, stars, or moon are in general so much less sharp than those cast ^{now} by the electric light (when it is not surrounded by a semi-opaque screen). For, practically, at moderate distances from the electric arc, it appears as a mere luminous point. But, if we place a body at a distance of a foot or two only from the arc, the shadow cast will have as much of penumbra as if the sun had been the source. The breadth of the penumbra when the source and screen are nearly equidistant from the opaque body is equal to the diameter of the luminous source. Simple as is the question from the point of view we have adopted, it may to some persons appear simpler to imagine themselves placed (as spectators) on the screen in different parts of the shadow or penumbra, and to consider what portions of the luminous source they would then be in a position to see.

This is what happens to us when we observe an eclipse. Eclipse of the sun. When the eclipse is total, there is a real geometrical shadow,—very small compared with the penumbra (for the *apparent* diameters of the sun and moon are nearly equal, but their distances are as 370 : 1); when the eclipse is annular, the shadow is all penumbra. In a lunar eclipse, on the other hand, the earth is the shadow-casting body, and the moon is the screen, and we observe things according to our first point of view.

Suppose, next, that the body which casts the shadow is light, a large one, such as a wall, with a hole in it. If we were passing through the hole, the whole screen would be in geometrical shadow. Hence the illumination of the screen by the light passing through the hole is precisely what would be cut off by a disk which fits the hole. Fig. 3, which is the

Fig. 3.

shadow. Hence the illumination of the screen by the light passing through the hole is precisely what would be cut off by a disk which fits the hole. Fig. 3, which is the

complement of fig. 1, gives therefore the effect of four equal sources of light shining on a wall through a circular hole. And it is evident that, with the change of a word here and there, the previous reasoning may be applied to this case also. The umbra in the former case becomes the fully illuminated portion, and vice versa.

The penumbra remains the penumbra, but it is now darkest where before it was brightest, and vice versa. For further information we subjoin the complement (fig. 4) of the second case above,—the same four sources, but the smaller hole.

Here we have four equally bright, separate images

labeled
by the
hole

Fig. 4

—one belonging to each of the sources. Thus we see how, when a small hole is cut in the window-shutter of a dark room, a picture of the sun, and bright clouds about it, is formed on the opposite wall. This picture is obviously inverted, and also reversed, for not only are objects depicted lower the higher they are, but also objects seen to the right are depicted to the left, &c. But it will be seen unperturbed (though still inverted) if it be received on a sheet of ground glass and looked at from behind. The smaller the hole (so far at least as Geometrical Optics is concerned) the less confused will the picture be. As the hole is made larger the illuminated portions from different sources gradually overlap, and when the hole becomes a window we have no indications of such a picture except from a body (like the sun) much brighter than the other external objects. Here the picture has ceased to be one of the sun, it is now a picture of the window. But if the wall could be placed 100 miles off, the picture would be one of the sun. To prevent this overlapping of images, and yet to admit a good deal of light, is one main object of the lens which usually forms part of the camera obscura.

The formation of pictures of the sun in this way is well seen on a calm sunny day under trees, where the sunlight penetrating through small chinks forms elliptic spots on the ground. During a partial eclipse these pictures have, of course, a crescent form. When detached clouds are drifting rapidly across the sun, we often see the shadows of the bars of the window on the walls or floor suddenly shifted by an inch or two, and for a moment very much more sharply defined. They are, in fact, shadows cast by a small portion of the sun's limb, from opposite sides alternately. Another beautiful illustration is easily obtained by cutting with a sharp knife a very small T aperture in a piece of note paper. Place this close to the eye, and an inch or so behind it place another piece of paper with a fine needle-hole in it. The light of the sky passing through the needle hole forms a bright picture of the T on the retina. The eye perceives this picture, which gives the impression of the T much magnified, but turned upside down.

Phenomenon
of light
observed

Another curious phenomenon may fitly be referred to in this connection, viz., the *phantoms* which are seen when we look at two parallel sets of palisades or railings, one behind the other, or look through two parallel sides of a meat-safe formed of perforated zinc. The appearance presented is that of a magnified set of bars or apertures which appear to move rapidly as we slowly walk past. Their origin is the fact that where the bars appear nearly to coincide the apparent gaps bear the greatest ratio to the dark spaces; i.e., these parts of the field are the most highly illuminated. The exact determination of the appearances in any given case is a mere problem of convergents to a continued fraction. But the fact that the

apparent rapidity of motion of this phantom may exceed in any ratio that of the spectator is of importance,—enabling us to see how velocities, apparently of impossible magnitude, may be accounted for by the mere running along of the condition of visibility among a group of objects no one of which is moving at an extravagant rate.

(b) Another important consequence of this law is that *illumination of the medium is transparent the intensity of illumination within which a luminous point can produce on a white surface directly exposed to it is inversely as the square of the distance.*

The word transparent implies that no light is absorbed or stopped. Whatever, therefore, leaves the source of light must in succession pass through each of a series of spherical surfaces described round the source as centre. The same amount of light falls perpendicularly on all these surfaces in succession. The amount received in a given time by a unit of surface on each is therefore inversely as the number of such units in each. But the surfaces of spheres are as the squares of their radii,—whence the proposition. (We assume here that the velocity of light is constant in the medium, and that the sources give out its light uniformly and not by fits and starts.) When the rays fall otherwise than perpendicularly on the surface, the illumination produced is proportional to the cosine of the obliquity; for the area seen under a given spherical angle increases as the secant of the obliquity, the distance remaining the same.

As a corollary to this we have the further proposition *English*—that the apparent brightness of a luminous surface (seen ^{near} at different distances through a transparent homogeneous medium) is the same at all distances.

The word brightness is here taken as a measure of the amount of light falling on the pupil per unit of spherical angle subtended by the luminous surface. The spherical angle subtended by any small surface whose plane is at right angles to the line of sight is inversely as the square of the distance. So also is the light received from it. Hence the brightness is the same at all distances.

The word brightness is often used (even scientifically) in another sense from that just defined. Thus we speak of a bright star, of the question—When is Venus at its brightest? &c. Strictly, such expressions are not defensible except for sources of light which (like a star) have no apparent surface, so that we cannot tell from what amount of spherical angle their light appears to come. In that case the spherical angle is, for want of knowledge, assumed to be the same for all, and therefore the brightness of each is now estimated in terms of the whole quantity of light we receive from it. It is in this sense ^{Maximum} that we use the word when we speak of Venus at its brightest, for if we take the former definition of brightness the solution of this once celebrated problem would be very different from that usually given. As the question, however, is an interesting one both in itself and historically, we give an approximate solution of it. The approximation assumes what is certainly not true, that the illuminated portion of Venus always appears *uniformly* bright, and of the same degree of brightness in all aspects.

Let a be the radius of the earth's orbit, b that of the orbit of Venus, d the distance between the planets when Venus is brightest. Then if θ be the apparent angular distance of the earth from the sun as seen from Venus, the illuminated part of the disk of Venus as seen from the earth is

$$\frac{1 + \cos \theta}{2}$$

of the whole disk. Hence

$$\frac{1 + \cos \theta}{2^2}$$

is a maximum,—with the obvious trigonometrical relation $a^2 = b^2 + d^2 - 2bd \cos \theta$.

Substituting for $\cos \theta$, and putting the differential coefficient $=0$, we have a quadratic equation of which the only admissible root is the positive one

$$r = \sqrt{3a^2 + b^2} - 2b.$$

From this the other quantities can be calculated.

Effect of contraction of pupil. But another matter has to be taken into consideration when we apply the above definition of brightness in practice. For the aperture of the pupil is usually very much contracted when we look at a brightly illuminated sky or cloud. Thus there is a rough compensation which, to a certain extent, modifies the effect on the retina.

Argument for finite number of stars. Founded on the above is Cheseaux's celebrated argument about the finite dimensions of the stellar universe. For it is easy to see, as below, that if stars be scattered through infinite space, with average closeness and brightness such as is presented by those nearest us, and if stellar space be absolutely transparent, the whole sky should appear of a brightness like that of the sun. Cheseaux and Olbers endeavoured to show that, because the sky is not all over as bright as the sun, there is absorption of light in stellar space. This idea was ingeniously developed by Struve.

Consider a small spherical angle ω . The number of stars included in it whose distances are between r and $r + \delta r$ from the earth is proportional to

$$\omega r^2 \delta r.$$

The whole amount of light received from such a portion of the sky must be therefore as

$$\int_0^{\omega} \delta r,$$

provided that no star intercepts the light coming from another. This condition is unattainable, so that the conclusion is that the brightness is as great as it can be with the materials employed. Every portion of the background shines as if it were a star.

Brightness at different obliquities. (c). A third very important fact, connected with our present subject, but not immediately deducible from our principle, is—*The brightness of a self-luminous surface does not depend upon its inclination to the line of sight.*

Thus a red-hot ball of iron, free from scales of oxide, &c., appears flat in the dark, so, also, the sun, seen through mist, appears as a flat disk. This fact, however, depends ultimately upon the second law of thermodynamics, and its explanation will be fully given under RADIATION.

It may be stated, however, in another form, in which its connexion with what precedes is more obvious—*The amount of radiation, in any direction, from a luminous surface is proportional to the cosine of the obliquity.*

General principles of the theory of illumination. The flow of light (if we may so call it) in straight lines from the luminous point, with constant velocity, leads as we have seen to the expression $\frac{\mu}{r^2}$ (where r is the distance from the luminous point) for the quantity of light which passes through unit of surface perpendicularly to the ray in unit of time, μ being a quantity indicating the rate at which light is emitted by the source. This represents the illumination of the surface on which it falls. The flow through unit of surface whose normal is inclined at an angle θ to the ray is of course

$$\frac{\mu}{r^2} \cos \theta,$$

again representing the illumination. These are precisely the expressions for the gravitation force exerted by a particle of mass μ on a unit of matter at distance r , and for its resolved part in a given direction. Hence we may employ an expression

$$V = \pm \frac{\mu}{r},$$

which is exactly analogous to the gravitation or electric potential, for the purpose of calculating the effect due to any number of separate sources of light.

And the fundamental proposition in potentials, viz., that if a be the element normal at any point of a closed surface, the integral

$$\iint \frac{aV}{dn},$$

taken over the whole surface, has the value

$$= 4\pi\mu.$$

where μ is the sum of the values of μ for each source lying within the surface, follows almost intuitively from the mere consideration of what it means as regards light. For every source external to the closed surface sends in light which goes out again. But the light from an internal source goes wholly out; and the amount per second from each unit source is 4π , the total area of the unit sphere surrounding the source.

It is well to observe, however, that the analogy is not quite complete. To make it so, all the sources must lie on the same side of the surface whose illumination we are dealing with. This is due to the fact that, in order that a surface may be illuminated at all, it must be capable of scattering light; i.e., it must be to some extent opaque. Hence the illumination depends mainly upon those sources which are on the same side as that from which it is regarded.

Though this process bears some resemblance to the least analogy employed by Sir W. Thomson for investigations in statistical electricity (*Cambridge Mathematical Journal*, 1844) and to Clerk Maxwell's device of an incompressible fluid without mass (*Proc. Phil. Trans.*, 1868), it is by no means identical with them. Each method deals with a substance, real or imaginary, which flows in conical streams from a source so that the same amount of it passes per second through every section of the cone. But in the present process the velocity is constant and the density variable, while in the others the density is virtually constant and the velocity variable. There is a curious reciprocity in formulae such as we have just given. For instance, it is easily seen that the light received from a uniformly illuminated surface is represented by

$$\iint \cos \theta \frac{\mu}{r^2}.$$

As we have seen that this integral vanishes for a closed surface which has no source inside, its value is the same for all shells of equal uniform brightness whose edges lie on the same cone.

We have said that light moves in straight lines in a homogeneous medium. This rectilinear path follows at rehearsal once from the corpuscular theory, as well as from the undulatory theory of light: in the first case there is no deflecting cause, so each corpuscle moves in a straight line; in the second, the direction of propagation of a plane wave progresses in a uniform isotropic medium is always perpendicular to its front. Looking along a hot poker or the boiler of a steamboat, we see objects beyond distorted; i.e., we no longer see each point in its true direction. Here we have a non-homogeneous medium, the air being irregularly expanded in the neighbourhood of the hot body. To homogeneous media, the reduplication of images of a distant object seen through an irregularly heaped atmosphere, the scintillation or twinkling of stars, and the uselessness of even the best telescopes at certain times, &c. It is interesting to note here that Newton says—"Long telescopes may cause objects to appear brighter and larger than short ones can do; but they cannot be so formed as to take away that confusion of the rays which arise from the tremors of the atmosphere. The only remedy is a most serene and quiet air, such as may perhaps be found on the tops of the highest mountains, above the grosser clouds."

PHOTOMETRY.—The principle above explained suggests many simple methods of comparing the amounts of light given by different sources. If, for instance, a porcelain plate, or even a sheet of paper, of uniform thickness, have one half illuminated directly by one source of light, the other by a different source, and if one or other of these sources be moved to or from the plate till the halves appear equally illuminated, it is obvious that the amounts of light given out by the two sources are directly as the squares of their distances from the screen. This is the principle of Ritchie's photometer. Rumford suggested the comparison of the intensity of the shadows of the same object thrown side by side on a screen by the two lights to be compared. In this case the shadow due to one source is

PHOTOMETRY.—The principle above explained suggests many simple methods of comparing the amounts of light given by different sources. If, for instance, a porcelain plate, or even a sheet of paper, of uniform thickness, have one half illuminated directly by one source of light, the other by a different source, and if one or other of these sources be moved to or from the plate till the halves appear equally illuminated, it is obvious that the amounts of light given out by the two sources are directly as the squares of their distances from the screen. This is the principle of Ritchie's photometer. Rumford suggested the comparison of the intensity of the shadows of the same object thrown side by side on a screen by the two lights to be compared. In this case the shadow due to one source is

* Express the formulae of which the proof has been indicated. Green's theorem, and the consequences, follow immediately. But we need not give these here.

* Option, end of part I.

lit up by the other alone, and here again the amounts of light given out by the sources are as the squares of their distances from the screen when the shadows are equally intense. The shadow-casting object should be near the screen, so as to avoid penumbra as much as possible; yet not too near, so that the shadows may not overlap.

Dansen's
photo-
meter.

Dansen has recently suggested the very simple expedient of making a grease-spot on white paper for photometric purposes. When the paper is equally illuminated from both sides, the grease-spot cannot be seen except by very close inspection. In using this photometer, the sources are placed in one line with the grease-spot, which lies between them and can be moved towards one or other. To make the most accurate determinations with this arrangement the adjustment should first be made from the side on which one source lies, then the screen turned round and the adjustment made from the side of the other source,—in both cases, therefore, from the same side of the paper screen. Take the mean of these positions (which are usually very close together), and the amounts of light are as the squares of the distances of the sources from this point.

Wheat-
stone's

Wheatstone suggested a hollow glass bead, silvered internally, and made to describe very rapidly a closed path, for use as a photometer. When it is placed between two sources, we see two parallel curves of reflected light, one due to each source. Make these, by trial, equally bright; and the amounts of light from the sources are, again, as the squares of the distances. These simple forms of apparatus give results which are fairly accurate, so long at least as the qualities of the light furnished by the two sources are nearly the same. But, when we endeavour to compare differently coloured lights, the result is by no means so satisfactory. In fact, we cannot well define equality of illumination when the lights are of different qualities. In the undulatory theory, no doubt, we can distinctly define the intensity of any form of radiation.

Difficul-
ties of
photo-
metry.

But the definition is a purely dynamical one, and has not necessarily any connexion with what we usually mean by intensity, viz. the amount of effect produced upon the nerves of the retina. Thus the theoretical intensities of a given violet and a given red source may be equal, while one may appear to the eye very much brighter than the other. Think, for instance, of a colour-blind person, who might, under conceivable circumstances, be unable to see the red at all. We are all as it were colour-blind as far as regards radiations whose wave-lengths are longer or shorter than those included in the range of the ordinary solar spectrum.

Chemical
photo-
metry.

Other modes of measuring the intensity of light usually depend upon more reconcitable physical principles,—such as, for instance, the amounts of chemical action of certain kinds which can be produced by an exposure of a given duration to the light from a particular source. But all have the same grand defect as the simpler processes,—they are not adapted to the comparison of sources giving different qualities of light. And those last mentioned are liable to another source of error, viz. the action of radiations which are not called light, only because they are not visible to the eye, for in all other respects they closely resemble light, and are often more active than it is in producing chemical changes.

Velocity
of light.

VELOCITY OF LIGHT.—Light moves with a velocity of nearly 186,000 miles per second. Of this we have four distinct kinds of proof, on each of which depends a method which is capable of giving pretty accurate results.

Römer's
method.

1. *Römer's Method*.—By this the finite velocity of light was discovered in 1676. Suppose, to illustrate this, that at a certain place a cannon is fired precisely at intervals of an hour while the weather is perfectly calm. A person

provided with an accurate watch travels about in the surrounding district. When he first hears the cannon let him note the time by his watch, then on account of the non-instantaneous propagation of sound, if at the next discharge he be *nearer* the gun than before, the report will arrive at his ear *before* the hour's interval has elapsed; if he be *further* from the gun, the interval between the discharges will appear longer than an hour; and the number of seconds of defect or excess will evidently represent the time employed by sound in travelling over a space equal to the difference of his distances from the gun at the successive observations.

Now the satellites of Jupiter are subject—like our moon, only much more frequently—to eclipses, and the interval between two successive eclipses can easily be observed. The almost sudden extinction of the light is a phenomenon similar to the discharge of the gun; and, if light take time to move from one place to another, we should find the interval between successive eclipses too short when we are approaching Jupiter, too long when we are receding from him. Such was found to be the case by Römer; and he also found that the shortening or lengthening of the interval depended upon the rate at which the earth was approaching to or receding from Jupiter. The inevitable conclusion from these facts is that light is propagated with finite velocity. Römer calculated from them that light takes about $16\frac{1}{2}$ " to cross the earth's orbit. The exact velocity deduced by this method is, after making all corrections, and assuming the most probable value of the solar parallax, about 186,600 miles per second.

2. *Bradley's Method*.—This depends on the aberration of Bradley's light, discovered by Bradley in 1728. When in a calm method, rainy day one stands still he holds his umbrella vertical in order to protect himself. If he walk he requires to hold it forwards, and more inclined the faster he walks. In other words, to a person walking the rain does not appear to come in the same direction as to a person standing still.¹ Now the earth's velocity in its orbit is a very large quantity, some $16\frac{1}{2}$ miles per second, or about $\frac{1}{1000}$ th of that of light. Hence the light from a star does not appear to come in the proper direction unless the earth be moving exactly to or from the star, and, as the direction of the earth's motion is continually changing, so the directions in which different stars are seen are always changing, and thus this phenomenon, called the "aberration of light," proves at once the finite velocity of light and the earth's motion round the sun.

As an additional illustration of the phenomenon, suppose a bullet fired through a railway carriage, in a direction perpendicular to the sides of the carriage. If the carriage be standing still, the bullet will make holes in the sides, the line joining which is perpendicular to the length of the carriage; if it be in motion, then the second side of the carriage will have moved through a certain space during the interval occupied by the bullet in passing from side to side, and thus the line joining the holes in the sides (i.e., the line pursued by the bullet relatively to the carriage), will be inclined at an angle greater than a right angle to the direction of the train's motion.

It is evident that the path apparently described by each star during a year, in consequence of aberration, will be found by laying off from the star lines which bear the same ratio to the star's distance as the velocity of the earth does to that of light,—their directions being always the same as that of the earth's motion at every instant. This is precisely the definition of the HODOGRAPH (η) of the earth's orbit. Hence, on account of the finite velocity of

¹ In fact, to estimate the relative direction and velocity of two moving bodies we must subtract the vector velocity of the first from that of the second.

light, each star appears to describe in space a circle (not an ellipse) of fixed magnitude in a plane parallel to that of the ecliptic. As seen from the earth, therefore, stars will appear to describe paths which are the projections of these circles on the celestial sphere. These are in general ellipses, but circles for stars at the poles of the ecliptic and straight lines for stars in the ecliptic. This is found to be quite consistent with observation, and the major axes of these ellipses, the diameters of the circles, or the lengths of the lines subtend equally angles of about $41''$ at the earth. Hence the velocity of light is to the velocity of the earth as $1 : \tan \frac{1}{2} 41''$, that is, about 10,000 : 1.

Do these methods depend, for their final result, upon a true knowledge of the earth's distance from the sun. But the most accurate measurements of this quantity are probably to be obtained from the velocity of light itself, this being independently determined by the physical processes next to be described. Thus the earth's distance from the sun will in future be measured rather by the constant of aberration, or by the acceleration or retardation of the eclipses of Jupiter's satellites, than by a transit of Venus, by the moon's motion, or by the parallax of Mars. Thus Romer's and Bradley's processes are now applied to the determination of solar parallax.

Foucault's method.

—3 *Foucault's Direct Measurement of the Velocity of Light.*—To illustrate the next and by far the most convincing popular proof of the finite velocity of light, suppose a person looking at himself in a mirror, before which is moving a screen with a number of apertures, the breadth of each aperture being equal to the distance between any two of them. If the screen be at rest with an aperture before the mirror, the light from the observer's face passes through the aperture and is reflected back, so that he sees himself as if the screen were not present. Suppose the screen to be moving in such a way that, when the light which passed through the aperture returns to the screen after reflection, the unperforated part of the screen is in its way, it is evident that the observer cannot see himself in the mirror. If the screen pass twice as fast, the light that escaped by one aperture will, after reflection, return by the next, so that he will see his image as at first. If three times as fast, the second unperforated part of the screen will stop the returning light, so he cannot see his image. To apply this practically a thin metallic disk had a set of teeth cut on its circumference so that the breadth of a tooth was equal to that of the space between two teeth. This disk could be set in very rapid rotation by a train of wheelwork, and the rate of turning could easily be determined by Savart's method (see *Acoustics*, vol. I. p. 108). Light passed between two teeth to a mirror situated at 10 miles' distance, which sent it back by the same course, so that when the wheel was at rest the reflected light could be seen. On turning the disk with accelerated velocity the light was observed to become more and more feeble up to a certain velocity, at which it was extinguished; turning faster it reappeared, growing brighter and brighter till the velocity was doubled; then it fell off, till it vanished when the velocity was trebled, and so on. It is evident from the first illustration above that the velocity of light in air is to that of the tooth, at the first disappearance of the reflected light, as the distance of the mirror from the disk is to the half breadth of the tooth. It is not to be supposed that the description we have just given embodies all the details of this remarkable experiment. On the contrary, telescopes were used at each station to prevent loss of light as much as possible, and many other precautions were adopted which would be unintelligible without references to later parts of this article. This method and its first results were published in 1849 in the *Comptes Rendus*. The experiments gave, on their very careful repetition by

Cornu in 1874, the value 186,700 miles for the velocity in *vacuo* (*Nature*, xi. p. 274).

4 *Foucault's Method.*—This was described in 1850 to Foucault's Academy of Sciences. It depends upon the principle of the rapidly revolving plane mirror introduced by Wheatstone to demonstrate the non instantaneous propagation of an electric discharge. The mirror was made to revolve from 600 to 800 times per second, by means of a *arcs* (see *Acoustics*) driven by steam. A ray of sunlight fell upon it from a small aperture crossed by a grating of platinum wires. Between the wires and the mirror was placed an achromatic lens—the wires being farther from it than its principal focus, but not twice as far—so that the rays falling on the mirror were slowly convergent. They formed an image of the wires at a distance of about 4 metres from the mirror. In certain positions of the revolving mirror, the rays fall upon a concave mirror of 4 metres radius whose centre of curvature was at the centre of the revolving mirror. They were, therefore, reflected back directly to the revolving mirror, and, passing again through the lens, formed an image of the wire grating which, when the adjustment was perfect, coincided with the grating itself. This coincidence was observed by reflexion from a piece of unannealed glass, placed obliquely in the track of the rays, the image in which was magnified by an eye-piece. It is obvious that, when the mirror is made to turn, the light which comes back to it after passing to the fixed mirror, finds it in a position slightly different from that in which it left it. That difference is due to the amount of rotation during the time of passage of the light to and fro along an air-space of 4 metres. Accordingly, as soon as the mirror began to rotate with considerable velocity, the coincidence between the wires and their images was destroyed; and the two were separated more and more widely as the velocity of rotation was increased. It was easy to calculate, from the measured dimensions of the apparatus, the amount of deflexion, and the rate of rotation of the mirror; the velocity of light. The rate of rotation was, of course, given by the pitch of the note produced by the discs.

Foucault's early results with this apparatus showed that the velocity of light which had been deduced from the old methods was too large; and he concludes his first paper by the statement that the determination of the distance of the earth from the sun must now be made by physical instead of astronomical methods. Foucault's process has recently been very considerably improved by Mitchell, who, in 1879, found for the velocity of light in *vacuo* 186,380 miles per second (*Nature*, vol. xxi. p. 226).

By interposing a tube filled with water, and having flat glass ends, between the fixed and revolving mirrors, Foucault found that (for the same rate of rotation) the displacement of the image was greater than before in the proportion of the refractive index of water to unity. Thus in air it was at once evident, by a mode of experimenting exposed to no possible doubt, that light moves faster in air than in water, and, therefore, as will be seen later, that the corpuscular theory of light must be abandoned.

Other methods of determining the velocity of light in air, and for comparing the velocity of light in air and water (on which depends the most definite proof of the erroneousness of the corpuscular theory), and in still and moving water, will be afterwards explained. They give results of very great value, but we cannot introduce them here, as they depend upon somewhat more recondite principles of physical optics.

It is interesting to observe that, as the nearest fixed star is probably about 200,000 times farther from us than the sun is, we now see such a star by light which left it more than three years ago. If, as is now supposed, ~~the light~~

TIME of
passage
of light
from the
object
-rays

(such as Mira Ceti) owe their rapid periodical changes of brightness to eclipses, and if different homogeneous rays travel with different velocities in free space, it is evident that such stars would show a gradual change of colour as they wax, and an opposite change as they wane. Nothing of the kind has as yet been observed, though it has been carefully sought for. Hence we have every reason to conclude that, in free space, all kinds of light have the same velocity. It will be seen later that *dispersion* has been accounted for by the different velocities of light of different wave-lengths in the same refracting medium,—this being a consequence of the ultimate grained structure of ordinary matter, which is on a scale not incomparably smaller than the average wave-length.

Behaviour of Light at the Common Surface of Two Homogeneous Media.

Effect at
a surface
of separa-
tion
between
two
media

When a ray of light, moving in one homogeneous medium, falls on the bounding surface of another homogeneous medium, it is in general divided into several parts, which pursue different courses. These parts are respectively—(a) reflected, (β) refracted (singly or doubly); (γ) scattered; (δ) absorbed.

In the first two categories the result is two or three rays of light pursuing definite paths according to laws presently to be given. The fraction of the incident light which is reflected is in general greater as the angle of incidence is greater. In one important class of cases the reflexion is *total*. But at direct incidence the reflected portion is much greater for some bodies, such as mercury, than for others, such as water or glass. In bodies which give no scattering, the refracted portion of a ray consists of all the non-reflected portion, and therefore usually diminishes as the angle of incidence increases.

In the third category the common surface of the two media becomes illuminated, and behaves as if it were itself a source of light, sending rays in all directions. It may be objected to this, that in many cases the rays are scattered while penetrating the second medium. But in such cases the second medium cannot be called *homogeneous*. This will come up for discussion when we treat of absorption and colours.

In the fourth category the light ceases for an instant to exist as light; but its energy may either become heat in the absorbing body, or it may again be given out by the absorbing body in the form of light, but of a *degraded* character. This is called *fluorescence*, or *phosphorescence*, according as the phenomenon is practically instantaneous or lasts for a measurable time.

In category (a) the light is sent back into the first medium; in (β) it penetrates into the second; in (γ) it goes, in general, mainly to the first; in (δ) it is shared by both.

Visi-
bility of
non-
luminous
objects

It is by scattered light that non-luminous objects are, in general, made visible. Contrast, for instance, the effects when a ray of sunlight in a dark room falls upon a piece of polished silver, and when it falls on a piece of chalk. Unless there be dust or scratches on the silver you cannot see it, because no light is given from it to surrounding bodies except in one definite direction, into which (practically) the whole ray of sunlight is diverted. But the chalk sends light to all surrounding bodies from which any part of its illuminated side can be seen; and there is no special direction in which it sends a much more powerful ray than in others. It is probable that if we could, with sufficient closeness, examine the surface of the chalk, we should find its behaviour to be of the nature of reflexion, but reflexion due to little mirrors inclined in all conceivable aspects, and at all conceivable angles, to the incident light. Thus scattering may be looked upon as ultimately due to

reflexion. When the sea is perfectly calm, we see in it one intolerably bright image of the sun only. But when it is continuously covered with slight ripples, the definite image is broken up, and we have a large surface of the water shining by what is virtually scattered light,—though it is really made up of parts each of which is as truly reflected as it was when the surface was flat.

We have spoken above of the behaviour of light at the Gradual common surface of two media. Now we do not by this phrase necessarily mean two media different in their chemical composition. We mean merely media *optically* different. Thus water with steam above it, and in very unusual cases layers of water or air of different temperatures, other give surfaces of separation at which reflexion and refraction may and do take place. But, except in such special cases, we rarely have an abrupt change, such as is necessary for reflexion, between two portions of the same substance in the same molecular state. In general the transition is gradual, and special mathematical methods must be applied for the purpose of tracing the behaviour of the ray, which is now really travelling in a non-homogeneous medium.

REFLEXION OF LIGHT.—It light be reflected from a Reflexion plane surface bounding two dissimilar isotropic media, the incident and reflected rays are in one plane with, and are equally inclined (on opposite sides) to, the perpendicular to the reflecting surface at the point of incidence. This is sometimes stated in the form—*The angles of incidence and of reflexion are equal to one another, and in one plane*. The best experimental proof of the truth of this statement is deduced from the use of a reflecting surface of mercury in observations with the mural circle. The graduation of such an instrument is the most perfect that human skill can accomplish, and no one has ever been able to find by it the slightest exception to the preceding statement.

The principle of Hadley's quadrant, and of the sextant as now used (an invention of Newton's), is founded on this fact. If a plane mirror on which a ray falls be turned through any angle about an axis perpendicular to the plane of reflexion, the reflected ray is turned through twice that angle. This is an immediate consequence of the above law. For, if the plane be turned through any angle θ , the perpendicular to it is turned through the same angle. Hence the angle between the incident ray and the perpendicular is increased or diminished by θ , and therefore that between the incident and reflected rays (which is double of this) is altered by 2θ . A plane mirror is now extensively used for the purpose of indicating, by the change of direction of a reflected ray, the motion of a portion of an instrument to which the mirror is attached. Thus the magnetometers of Gauss, the tuning-forks of Lissajous, and the electrometers and galvanometers of Sir W. Thomson are all furnished with mirrors. The law of reflexion is also the basis of the goniometer, for the measurement of the angles of crystals and prisms.

It follows from this law that, if a ray pass from one point to another, after any number of reflexions at fixed surfaces, the length of its whole path from one point to the other is the least possible—subject to the condition that it shall meet each of the reflecting surfaces. For the point in a given plane the sum of whose distances from two given points (on the same side of the plane) is the least possible is that to which, if lines be drawn from the points, they are in one plane with the normal (or perpendicular) to the given plane and make equal angles with it. And, as the same is true of each separate reflexion, it is true for the whole course of the ray, since for any one of the reflecting surfaces may be substituted its tangent plane at the point of incidence.

It is to be remarked that there are exceptions to this form of the statement. The true form is, that the actual path of a ray, under the given conditions, is less in length than any other path (satisfying the conditions) which is nowhere faintly divergent from it. This may be best seen by another method. Suppose a series of ellipses to be described whose foci are the source of light and an assigned point which it is to be reached by the reflected ray. Let this system turn about the line joining the foci, it generates a series of prolate spheroids, such that the time of light's passing from one focus to a point in any one of the surfaces, and thence to the other focus, is the same whatever point be chosen on that particular surface. If we take any point *without* that surface, find the corresponding time as obviously greater. Hence to find the path of that one of a system of rays diverging from a given point which, after reflection at a given surface, shall pass through a given point, we have only to imagine spheroids constructed as before. Of these one at least will touch the given surface. All points on the surface is the *nearest point* of the point of contact (mark this limitation) will in general be outside the spheroid. Hence this point gives the shortest path. But the spheroid and the reflecting surface have the same tangent plane, and therefore the parts of the ray are equally inclined to the surface.

Images by reflection

Formation of Images by Reflection at a Plane Surface.—We may assume here—what is indeed evident from the rectilinear propagation of light—that objects are rendered visible to the eye by rays *diverging* from them. Hence, if we have a set of reflected or refracted rays diverging from any point, or diverging as if they came from any point, they will convey to the eye the impression of the existence of a luminous source at that point. The eye, in fact, can only tell us what effect is produced upon it, i.e., what sort of mechanical action it is subjected to. Its indications must therefore depend only upon what reaches it, and in no other sense whatever upon the source or the path of light. This point from which rays diverge, or appear to diverge, is called an *image*.

The image of any point in a plane mirror is found by drawing from the point a perpendicular on the mirror and producing it till its length is doubled.

The extremity of the line so drawn is the image of the point; or, in other words, rays proceeding from the point *diverge* after reflection as if they came from the image so found. The image in this case is called *virtual*, to distinguish it from cases, subsequently to be mentioned, where it is *real*—the distinction being that the rays have actually passed through a real image, while they only appear to come from a virtual one.

To prove this it is only necessary to observe that, if A (fig. 5) be a luminous point or a point from which rays

Real and virtual images.

Fig 5

diverge, and CB any section of the mirror by a plane through AB, the perpendicular to it, and if we make Ba=AB, and take any point P, then, joining AP, aP, and producing the latter, the angles APB, aPB, and therefore CPQ are equal; also the plane of the paper contains the perpendicular to the mirror at P. Hence PQ is the reflected ray; or the ray, after reflection, appears

to come from a. Hence a is the image—a virtual one, as before noticed. Also, if R be any point whatever (not P) in the plane of the mirror, we have obviously aR=RA. Hence the path AR, RQ is equal to aR, RQ, two sides of the triangle aRQ, of which aQ, which is equal to the actual path (AP, PQ), is the third side.

Fig. 6 represents the pencils of diverging rays by which two points of the image are rendered visible to an eye placed in front of the mirror.

From the requisite modification of this figure it follows that one can see his whole person in a mirror of only half his height and breadth.

Duck's ghost, which has played a prominent part in popular entertainments for some years back, is the image, in a large sheet of unsilvered

Duck's ghost

Fig 6

plate glass hung at the front of the stage, of an actor or figure strongly illuminated, and concealed from the audience in a sort of enlarged prompter's box. Any one can see the phenomenon completely by looking into a plate-glass window on a sunny day, when he sees the passers-by apparently walking *inside* the house.

The principles already stated suffice fully for the explanation of the curious vistas of images formed by two *parallel* plane mirrors facing one another at opposite sides of a room. The only additional observation necessary on this subject is that, if the mirrors are silvered on the back, the light at each reflexion has to pass twice through the glass. Thus, if the glass be pinkish or greenish, the various images are more and more coloured as they are due to more numerous reflexions.

These principles also easily explain the KALEIDOSCOPE (qv) of Sir D. Brewster, where images are formed by two mirrors inclined to one another.

It is easy to see that the series of images of a luminous point produced by such an arrangement after one, two, &c., reflexions must all lie on a circle, also that, if the angle between the mirrors be an aliquot part of four right angles, these images will form a finite number of groups, each consisting of an infinite number of images which have exactly the same position.

The explanation of the law of reflection which is furnished by the corpuscular theory is excessively simple. We have only to suppose that at the instant of its impact on the reflecting surface the velocity of a corpuscle *perpendicular* to the surface is reversed, while that *parallel* to the surface is unchanged. It bounces off, in fact, like a billiard-ball from the cushion. The undulatory theory gives an explanation, which is, in reality, quite as simple, but requires a little more detail for those who are not familiar with the common facts of wave-motion. We therefore reserve it for a time.

Reflection at a Spherical Surface.—Let APB (fig. 7) be Spherical a section of a concave spherical mirror by a plane passing through its centre of curvature O, and through the luminous point U. Then, if any ray from U, as UP, meet the surface, it will be reflected in a direction PV, such that UP, PO, and PV are in one plane, and so that PO bisects

the angle UPV (This follows because OP , a radius of the sphere, is normal to the surface at P). Hence it is

Fig 7

approximately true that, if V be the intersection of PV with OU ,

$$\frac{VO}{AV} = \frac{OU}{UP}$$

The full consequences of this *exact* statement will be developed under OPTICS (GEOMETRICAL). For our present purpose, an approximation will amply suffice. Let us suppose P to be so near to A that no sensible error is introduced by writing A for P in the above formula. This amounts to supposing the mirror's breadth to be very small in comparison with its radius of curvature. The formula now becomes

$$\frac{VO}{AV} = \frac{OU}{AU}$$

or, what is the same,

$$\frac{AO - AV}{AV} = \frac{AU - AO}{AU}$$

and V is, to the degree of approximation above stated, independent of the position of the point P . If we call r the radius AO of the mirror, $u = AV$ the distance of the source, and $v = AU$ the distance of the point V from the mirror, this becomes

$$\frac{r - v}{u} = \frac{r}{v}, \text{ or } \frac{1}{u} + \frac{1}{v} = \frac{2}{r}. \quad (a)$$

The formula, or the out, shows at once that this relation between U and V is *reversible*, i.e., all rays from V , falling on the mirror, will be made to converge at U . These points are therefore called *conjugate foci*.

The simplicity of (a) is remarkable, so, also, is that of its interpretation. For the rays passing from a source to a given object, like the mirror, are less and less divergent as the source is farther off. Hence (a) signifies that the (algebraic) sum of the divergences of the incident and reflected rays is equal to that divergence which the mirror can convert into parallelism.

In fact the rigorous geometrical relation may be written in the obvious form $AVP - AUP = 2\Delta OP$,—which, when all three angles are small, is simply (a). A similar statement may easily be made in the case of refraction.

Before we proceed to develop the consequences of this simple formula, we may point out that it is applicable to all cases,—to convergent rays falling on a concave mirror, to divergent rays falling on a convex mirror, &c., &c. The reader may easily verify this by trial for himself. But it follows at once from the necessary interpretation of the negative sign in geometry. Thus, if the mirror were convex, O would be to the *left* of A , as the figure is drawn, and AO , if formerly positive, would now be negative. Thus, for a convex mirror, the formula is

$$\frac{1}{u} + \frac{1}{v} = -\frac{2}{r}$$

If the incident rays be *emergent*, U is to the left of A , and therefore AU , or v , is negative; and so on.

We must now study the *relative* positions of U and V , in order to find the size and position of the image for different positions of the object.

Returning to the formula (a) above, we see that the following pairs of values of u and v satisfy it:—

u	v
Infinite	$\frac{r}{2}$
Greater than r	Greater than $\frac{r}{2}$, less than r
r	∞
Less than r , greater than $\frac{r}{2}$	Greater than r
$\frac{r}{2}$	Infinite
Greater than 0, less than $\frac{r}{2}$	Negative
0	0

Thus, when the source is at a practically infinite distance (as the sun or a star) the image is formed at a distance f from the mirror equal to *half* its radius of curvature. It is then said to be in the *principal focus*. As the source comes nearer, the image comes out to meet it, and they coincide at the centre of curvature of the mirror. In fact, a ray leaving the centre of the mirror must meet the surface at right angles, and thus go back by the way it came. When the source comes still nearer, the image goes further off, until, when the source is at the principal focus, the image is at an infinite distance, that is, the rays go off parallel to one another. This is the mode in which a concave reflector is employed for lighthouse purposes. When the source comes still nearer, the image is behind the mirror, i.e., the incident rays are so divergent that part of their divergence remains after reflexion. This remnant of divergence becomes greater and greater as the source is nearer to the mirror, i.e., the (then *virtual*) image comes closer to the mirror, which finally behaves, for a very near source, almost precisely like a plane mirror.

All of these phenomena can be beautifully seen in a dark room by employing a beam of sunlight, rendered distinctly visible, in the fashion noted by Lucretius, by the motes in the air.

For further explanation pictures are given (figs 8, 9). Paths of showing the course of the pencil of rays when (1) a *real* object forms an image.

Fig 8

Fig 9

and (2) a *virtual* image is formed by a concave mirror. It will be seen at once that, in the cases figured, the *real* image is *inverted* and less than the object, the *virtual* image *erect* and larger. In fact the size of a small object is obviously to that of its image in proportion to their distances from O , the centre of curvature of the mirror. Also the image is erect when it lies on the same side

of the centre of curvature with the object, inverted, if on the opposite. In other words, the image is inverted if the rays cross one another's path, erect if they do not.

Caustics

When the breadth of the mirror is large compared with its radius, the approximation upon which all these results depend can no longer be made. There is then no definite image even of a luminous point. It becomes spread over what is called a *caustic*, a section of which is the bright curve familiar to every one who has looked at a cup of milk in sunshine.

Spherical aberration

Even when the approximation is close enough for ordinary purposes, it is not so for astronomical purposes, and the effect of its inexactness upon the image is known as *spherical aberration*. For the fine mirrors of reflecting **TELESCOPES** (γ) the spherical form cannot be employed, the surface of the mirror must be of *parabolic* section.

Cylindrical mirror

Cylindrical Mirrors.—As a simple example of the application of the law of reflexion at curved surfaces, when the rigorous solution is demanded, let us take the case of a vertical right cylinder, the object being a drawing on a horizontal plane. Such mirrors, with the frightfully distorted drawings, necessary to give an image of natural proportions, were very common fifty years ago, but are now rarely seen. They are still, however, valuable as illustrations of our subject.

Let the plane of the object cut the axis OB of the cylinder at right angles in O (fig 10), and let A be the position of the eye, and BOA a ray from a point B of the object, reflected at Q. Draw QP perpendicular to the axis. Then AQ and QR are in the same plane with QP (the normal to the surface) and make equal angles with it. Hence, when this figure is projected by vertical lines on the plane of the object, it takes the form in fig 11, and AQ, QR now make equal angles with OQ. Also, if AB be drawn (in fig 10) perpendicular to OF, the ratio of AQ to QB in fig 11 is equal to that of BP to FO in fig 10.

Fig. 10.

Fig. 11

Take OS, QO, QR, QA, and draw ST parallel to OA. Then it is obvious that $SR = ST = \frac{QS \cdot OA}{QO}$;

and also that the angles QSR and QST are equal. Hence the following theorems, which enable us at once to draw a figure on the object plane such that its image shall appear of any assigned form.

1. Any line, such as QR, on the object plane, drawn from a point Q in the section of the cylinder so that the angles QQR and QQA are equal, is seen after reflexion as a generating line of the cylinder.

2. If an epicycloid be described by lines of fixed length OS, SR, turning about O with angular velocities 1 and 2, and both coinciding with OA at starting, its image will be a circular section of the cylinder.

Thus, if we imagine as drawn on the cylinder any number of vertical and horizontal sections, forming a network, the object corresponding to them can be traced as a number of intersecting straight lines and epicycloids. Thus we have a well-known means of drawing the required object. A similar process may be applied to other modes of using such mirrors.

Diagrams for cylindrical mirror

When the cylinder has a small diameter, it may be usefully employed to intercept and reflect part of a beam of sunlight entering a dark room. It is easy to see, by a geometrical construction, that the reflected rays will, in this case, form a right cone, whose axis is that of the cylinder; and one of its generating lines will be parallel to the incident ray. Thus the angle of the cone becomes smaller as the inclination of the reflecting cylinder to the ray becomes less. If the ray, at the point of interruption, was at the centre of a spherical dome, after reflexion it will form on the dome a circle, small or great, which passes through its original point of incidence.

Reflection from polished metal

In the language of QUATERNIONS (γ), let α be the incident ray, β the axis of the cylinder, τ any normal to the cylinder, ρ the reflected ray. Then the law of reflexion gives

$$\nabla \cdot \tau \rho \alpha = 0$$

The property of the normal gives

$$S\beta\tau = 0.$$

Eliminating τ , we have at once

$$\frac{\rho^2}{\alpha^2} = \left(\frac{S\beta\rho}{S\alpha\beta} \right)^2,$$

the equation of a right cone.

Imitations, more or less perfect, of primary and secondary rainbows can easily be made by this process,—the sunbeam being led through a prism just before it falls on the cylindrical rod. This experiment is a very striking one, but, though capable of giving much information, it is of that dangerous kind which is liable to mislead instead of instructing an audience.

If we look at a great number of thin cylindrical rods, parallel to one another, and illuminated by sunlight, the rays which reach the eye must, by what we have already said, each form a side of some right cone (of definite angle) whose axis is parallel to each of the cylinders. The appearance presented will therefore be that of a luminous circle, passing through the sun. Its angular diameter becomes less as the axes of the cylinders are less inclined to the incident rays.

This phenomenon is beautifully shown by some specimens of crystals, especially of Iceland spar, which are full of minute tubes parallel to one another. In a plate of such a doubly-refracting crystal, however, there are necessarily four images. That which is *throughout* due to the ordinary ray (this term will be explained later) shows perfectly the phenomenon above described. The light of the luminous circle is white. The other three curves are not circles, and in them the colours are separated. One of them, which is elliptical, is usually very much brighter than either of the remaining two.

REFRACTION.—If homogeneous light be refracted at a Ordinary plane surface separating two homogeneous isotropic media, the incident and refracted rays are in one plane with the normal to the surface, and the sines of their inclinations to it are in a constant ratio

Refraction

The law of single refraction was put in a form equivalent to this (all but one word) for the first time by Snell in Leyden, some time before 1626. It was first published in 1637 by Descartes, who undoubtedly obtained it from Snell; but he gave it without any mention of its author.

The one word referred to is *homogeneous* as applied to the incident light. For the fact that white light consists of innumerable different homogeneous constituents, which are separated from one another by refraction, was first established by Newton. We quote his own account of this important discovery from his letter to Oldenburg, dated Feb. , 1672:—

Newton
on the
composition
of
white
light.

"To perform my late promise to you, I shall without further ceremony acquaint you, that in the year 1666 (at which time I applied myself to the grinding of peack-glasses of other figures than spherical) I procured me a triangular glass-prism, to try therewith the celebrated phenomena of colours. And in order thereto, having darkened my chamber, and made a small hole in my window-shutts, to let in a convenient quantity of the sun's light, I placed my prism at its entrance, that it might be thereby refacted to the opposite wall. It was first a very pleasing divertissement, to view the varied and mixt colours produced thereby, but after a while applying myself to consider them more circumspectly, I became surpris'd to see them in an oblong form, which, according to the received laws of refractions, I expected should have been circular. They were terminated at the sides with straight lines, but at the ends the decay of light was so gradual, that it was difficult to determine justly what was their figure, yet they seem'd semicircular.

"Comparing the length of this coloured spot with its breadth, I found it about five times greater; a disproportion so extravagant, that it could not be a mere effect of the irregularity of grinding from whence it might proceed. I could scarce think, that the various thickness of the glass, or the termination with shadow or darkness, could have any influence on light to produce such an effect. Yet I thought it not amiss, first to examine these circumstances, and so tried what would happen by transmitting light through parts of the glass of divers thicknesses, or through holes in the window of divers bignesses, or by setting the prism without, so that the light might pass through it, and be refacted, before it was terminated by the hole: but I found none of those circumstances material. The fashion of the colours was in all these cases the same.

"Then I suspected, whether by any unevenness in the glass, or other contingent irregularity, these colours might be thus dilated. And to try this, I took another prism like the former, and so placed it, that the light passing through them both, might be refacted contrary ways, and so by the latter returned into that curve from which the former had diverged it. For by this means I thought the regular effects of the first prism would be destroyed by the second prism, but the irregular ones more augmented, by the multiplicity of refractions. The event was, that the light, which by the first prism was diffus'd into an oblong form, was by the second reduced into an orbicular one, with as much regularity as when it did not at all pass through them. So that whatever was the cause of that length, it was not any contingent irregularity.

"I then proceeded to examine more critically, what might be effected by the difference of the incidence of rays coming from divers parts of the sun, and to that end, I measured the several lines and angles belonging to the image. Its distance from the hole or prism was 22 foot, its utmost length 12½ inches, its breadth 2½; the diameter of the hole ½ of an inch. The angle which the rays, tending towards the middle of the image, made with those lines, in which they were here proceeded without refraction, was 44 deg. 56 min. and the vertical angle of the prism 68 deg. 19 min. Also the refractions on both sides the prism, that is, of the incident and emergent rays, were, as near as I could make them, equal; and consequently about 64 deg. 4 min. And the rays fell perpendicularly upon the wall. Now embracing the diameter of the hole from the length and breadth of the image, there remains 13 inches in the length, and 2½ the breadth, comprehended by those rays which passed through the center of the said hole; and consequently the angle of the hole, which that breadth subtended, was about 81 min. measurable to the sun's diameter; but the angle which its length subtended, was more than 5 such diameters, namely, 2 deg. 49 min.

"Having made these observations, I first computed from them the refractive power of that glass, and found it measured by the ratio of the sines 20 to 81; and then by that ratio I computed the refractions of two rays flowing from opposite parts of the sun's discus, so as to differ 81 min. in their obliquity of incidence, and found that the emergent rays should have comprehended an angle of about 81 min. as they did before they were incident.

"But because this computation was founded on the hypothesis of

the proportionality of the sines of incidence and refraction, which though by my own experience I could not imagine to be so erroneous, as to make that angle but 81 min. which in reality was 2 deg. 49 min. yet my curiosity caused me again to take my prism and having placed it at my window, as before, I observed, that by turning it a little about its axis to and fro, so as to vary its obliquity to the light, more than an angle of 4 or 5 degrees, the colours were not thereby sensibly translated from their place on the wall; and consequently by that variation of incidence, the quantity of refraction was not sensibly varied. By this experiment, therefore, as well as by the former computation, it was evident, that the difference of the incidence of rays, flowing from divers parts of the sun, could not make them after decumescence diverge at a sensibly greater angle, than that which they before converg'd; which being at most but about 81 or 83 min. these still remained some other cause to be found out, from whence it could be 2 deg. 49 min.

"Then I began to suspect, whether the rays, after their impaction through the prism, did not move in curve lines, and according to their more or less curvity, tend to divers parts of the wall. And it increased my suspicion, when I remembered that I had often seen a tennis-ball, struck with an oblique racket, describe such a curve line. For, a circular as well as a progressive motion being communicated to it by that stroke, its parts, on that side where the motion concurs, must press and beat the contiguous air more violently than on the other, and there exists a salientcy and re-action of the air proportionably greater. And for the same reason, if the rays of light should possibly be globular bodies, and by their oblique passage out of one medium into another acquire a circulating motion, they ought to feel the greater resistance from the ambient matter, on that side where the motions concur, and therefore be continually bowed to the other. But notwithstanding this plausible ground of suspicion, when I came to examine it, I could observe no such curvity in them. And besides (which was enough for my purpose) I observed, that the difference betwixt the length of the image and the diameter of the hole, through which the light was transmitted, was proportionable to their distance.

"The gradual removal of these suspicions at length led me to the *experimentum crucis*, which was this. I took two boards, and placed one of them close behind the prism at the window, so that the light might pass through a small hole, made in it for that purpose, and fall on the other board, which I placed at about 12 feet distance, having first made a small hole in it also for some of that incident light to pass through. Then I placed another prism behind this second board, so that the light impacted through both the boards might pass through that also, and so again refracted before it arriv'd at the wall. This done, I placed at my right hand, and turn'd it to and fro slowly about its axis, so much as to make the several parts of the image, cast on the second board, successively pass through the hole in it, that I might observe to what places on the wall the second prism would refract them. And I saw, by the variation of these places, that the light, tending to that end of the image towards which the refraction of the first prism was made, did in the second prism suffer a refraction considerably greater than the light tending to the other end. And so the true cause of the length of that image was detected to be no other, than that light is not uniform or homogeneous, but consists of *diverse rays*, some of which are more refrangible than others, so that without any difference in their incidence on the same medium, some shall be more *refracted* than others, and therefore that, according to their particular degree of refrangibility, they were transmitted through the prism to divers parts of the opposite wall."

The constant ratio mentioned in the above statement of Rømer's law of refraction is called the *refractive index*. Its true numerical value depends upon the nature of the two media, ^{index} and also upon the quality of the homogeneous light. It is usually greater for orange light than for red, for yellow than for orange, and so on,—so that the violet rays are often called the "more refrangible" rays.¹

The following experimental facts are additions to the law.

When refraction takes place from a rarer into a denser medium, the angle of refraction is usually less than that of incidence.

If the refractive index for a particular kind of light from a medium A into another B be μ , that from B to A is $\frac{1}{\mu}$.

In other words, a refracted ray may be sent back by the path by which it came.

If μ_1 be the refractive index for a particular ray from A

¹ This statement is, however, liable to some very singular exceptions, which will be mentioned later, when we are dealing with anomalous dispersion.

into B, and μ_2 that for the same ray from A into C, that from B into C is $\frac{\mu_2}{\mu_1}$.

These being premised, let us consider a source of homogeneous light in air shining on a surface of water. Here we may take μ as about equal to $\frac{4}{3}$.

Let MN (fig 12) be the perpendicular to the water surface at the point where the incident ray AP meets it. In the plane APM make the angle QPN such that:

$$\sin \angle APM = \frac{3}{4} \sin \angle QPN,$$

then PQ is the refracted ray. If QP be produced backwards to meet the vertical line BA in g, we may present this statement in the form

$$\frac{FB}{FA} = \frac{PD}{PQ},$$

or

$$PA = \frac{3}{4} PQ$$

If the rays fall nearly perpendicularly on the surface, we may put (approximately) B for P, and we have

$$Bq = \frac{3}{4} BA$$

Hence, an eye placed under water

and nearly in the vertical through A, sees a virtual image of A at g, one third farther from the surface of the water

As P is taken farther and farther from A, the angle of incidence becomes more nearly a right angle, and the sine of the angle of refraction becomes more nearly equal to $\frac{3}{4}$.

A ray cannot go from air into water so as to make, with the perpendicular to the surface, an angle whose sine is greater

Fig 12

Fig 13

than $\frac{3}{4}$. The true nature of this curious statement is, however, best seen when we suppose the source to be under water, and the light to be refracted into air. If APQ (fig 13) be the course of a ray, we have as before

$$AP = \frac{3}{4} PQ$$

Hence, if P_1 be taken so that

$$AP_1 = \frac{3}{4} P_1 B,$$

it is clear that g coincides with B, or the ray AP₁, refracted at P₁, runs along the surface of the water. If AP₁ be less than $\frac{3}{4}$ P₁B, no point g can be found, so that the ray AP₁ cannot get out of the water. It is found to be completely reflected in the water. This reflexion unaccompanied by refraction is called *total reflexion*. The limiting angle of incidence (at P₁) which separates the totally reflected rays

from those which (at least partially) escape into air is called the *critical angle*. When an equilateral triangular prism of glass is placed in a ray of sunlight, and made to rotate, we see (besides the spectra formed by refraction) beams of white light reflected alternately from the outside and the inside of each face. The totally reflected ray from the inside is seen to be very much brighter than that reflected from the outside.

To an eye placed nearly in the vertical of A, A appears at A₀, where

$$A_0 B = \frac{3}{4} AB$$

Thus a clear stream, when we look vertically into it, appears to be of only $\frac{3}{4}$ ths of its real depth. But when we look more and more obliquely, seeing A for instance by the ray QP, the image appears nearer and nearer to the surface; or, if A be at the bottom, the water will appear more and more shallow; and all objects in it will appear to be crowded towards the surface. Thus the part of a stick immersed in water appears bent up towards the surface of the water.

Again, to an eye at A, all objects above the water will be seen within a right cone of which AB is the axis and AP, a side. The rest of the water surface, outside the cone just mentioned, shows us objects at the bottom by reflexion in a perfect mirror.

All this is on the supposition that the light is homogeneous. But when white light is emitted by A, the point A₀ will be nearer the surface for each constituent the greater is the refractive index. Thus a white point at A will appear drawn out into a coloured line whose lower end is red and upper end violet.

It is easily seen from the law of refraction that light, on passing through a plate of homogeneous material with parallel faces, finally emerges in a direction parallel to that at incidence, and therefore white light comes out from it still white. If the plate be water in a glass vessel with parallel sides, a body placed close to one side, while the eye is close to the other, appears to be at $\frac{3}{4}$ ths of its real distance from the eye.

The explanation of the law of refraction, on the corpuscular theory, was given by Newton. It is still of importance, as the earliest instance of the solution of a problem involving molecular forces. Newton shows that, as the molecular forces on a corpuscle balance one another at every point inside either of the media, its velocity must be constant in each, but that in passing through the surface of separation of the two media the square of the velocity perpendicular to the surface undergoes a finite change.

Thus, if v be the velocity in air, a the angle of incidence, then in glass the velocity parallel to the surface is still v sin a, but that perpendicular to the surface is $\sqrt{v^2 \cos^2 a + c^2}$. Thus the whole velocity is $\sqrt{v^2 + c^2}$, and, if a' be the angle of refraction,

$$\sqrt{v^2 + c^2} \sin a' = v \sin a.$$

Prisms—When the surfaces are plane, but not parallel, Prisms. we have what is called a prism.

The general nature of the action of a prism will be easily understood by the help of the previous illustrations, if we restrict ourselves to the case of a prism of very small angle and to rays passing nearly perpendicularly to each of its faces. Thus, the rays falling nearly at right angles to its surface from a point A (fig 14) will, after the first refraction, appear to diverge from a luminous line RV, red at the end next to A, violet at the other. This line is in the perpendicular AB from A to the first surface of the prism. Draw from R and V perpendiculars RS, VT to the second surface of the prism. Join BS, BT, and draw Ar, Av parallel to them so as to cut RS in r and VT in v. To an eye behind the prism, the bright point A will appear to be drawn out into a coloured line rv, red at the end nearest to A.

If A be a narrow bright line of light, parallel to the edge of the prism, it will appear to be drawn out into a rectangle consisting of images of the line ranged parallel to one another, and due to the various homogeneous constituents of white light in order of their refrangibility. If the light do not contain rays of every degree of refrangibility, some of these images will be wanting, and there will be corre-

Fig 14

sponding dark lines or bands crossing this spectrum (as it is called). The amount by which any part of this spectrum is shifted from the true position of the bright slit depends (*ceteris paribus*) upon the amount of the refraction. It also depends on the angle of the prism. And, for a given angle, the length of the spectrum depends upon the difference between the refractive indices for the red and the violet rays. This is called the *dispersion*.

If a second prism, of the same glass, and of the same angle, as the first, be placed in a reversed position behind it (as indicated by the dotted lines in the figure), the effect of the two would be simply that of a plate of glass with parallel faces, the emergent rays would each be parallel to its original direction, and there would be no separation of colours. The reversed prism would therefore undo the work of the direct prism. Then we should have no dispersion, but we should also have no refraction. We have, however, as has already been shown, an increase of divergence, &c., the image is nearer to the eye than the object. Blair, Brewster, and Amici devised combinations of two pairs of prisms of the same glass, those of each pair having their edges parallel, such that the combination acted as a sort of achromatic telescope of low power.

Newton, from some rough experiments, hastily concluded that the amount of dispersion is in all substances proportional to that of the refraction. If such were the case it is easy to see that prisms of two differently refracting materials and of correspondingly different angles, combined (as above described) so as to annul the dispersion, would likewise annul the refraction. Thus Newton was led to suppose that refraction without dispersion is impossible.

It was found by Hall in 1733, and afterwards (independently) by Dollond, that this idea is incorrect—that, in fact, we have in certain media large refraction with com-

paratively small dispersion, and *vice versa*, and thus that the dispersion may be got rid of while a part of the refraction remains. James Gregory had previously conjectured that this might be done by using, as is done in the eye, more media than one. Thus we have for certain specimens of flint and crown glass, whose optical constants were carefully measured by Fraunhofer, the following values of the refractive index for three definite kinds of homogeneous light —

	C	D	F
Flint glass.	1.6297	1.6350	1.6483
Crown glass.	1.5268	1.5298	1.5340

The rays C and F are in the red and greenish blue respectively, and are given off by incandescent hydrogen. D is the orange-yellow ray of sodium.

When the angle of the prism is very small (the only case we treat here), we may consider Ax as approximately a straight line, whose length is (*ceteris paribus*) proportional to the angle of the prism. Also the distances Ar , Ax , are to one another in the proportion of the refractive indices of red and violet rays, each diminished by unity. Hence, for a prism of flint glass such as was employed by Fraunhofer, the distances from A to its images formed by these three kinds of homogeneous light respectively are very nearly as

630, 635, 648

When a prism of crown glass is used they are nearly as

627, 630, 636

The differences between the numbers for C and F are

For flint glass	18
„ crown glass	9

as 2 : 1. Hence if we make the small angle of the crown-glass prism twice that of the flint, and observe A through the two prisms, with their edges turned in opposite directions, the C and F images will coincide. Both, however, will be displaced from the real direction of A as if a prism had been employed, with its edge turned as that of the crown glass was, and to the same extent as that prism would have displaced them had its refractive index been about 1.31 and the same for the two kinds of light C and F.

In fact, the displacements by the flint prism are as

630, 648,

and those by the crown prism (to the opposite side) are as

1651, 1672

The differences, in favour of the crown prism, are as

424, 424

This combination of prisms is called *achromatic*, or colourless, but is not perfectly so. For if we inquire into the displacement of the D image, we find that it is as

635

for the flint prism, but as

1080

in the opposite direction, for the crown prism. Hence its whole displacement is as

125,

a little greater than that common to C and F. The reason for this is obvious from Fraunhofer's numbers given above. The interval from C to D is to that from C to F in a greater ratio in crown than in flint glass,—so that the spectra given by these media are not similar. The rays of higher refrangibility are more separated in proportion to those of lower refrangibility in flint than in crown glass. This is the *irrationality of dispersion*—which, so far as we yet know, renders absolute achromatism unattainable. Three lenses in combination give a better attempt at achromatism than can be made with two, and some re-

markable results were obtained by Blair,¹ with two glass lenses enclosing a lenticular portion of a liquid.

LAYS IN
the SOLA
SPECTRUM

By looking through a prism at a very narrow slit formed by the window shutters of a darkened room, Wollaston (in 1802) found that the light of the sky (*i.e.*, sunlight) gives a spectrum which is *not continuous*. It is crossed by dark bands, as already hinted. These bands are due to the deficiency of intensity of certain definite kinds of homogeneous light. They were, independently, rediscovered, and their positions measured, by Fraunhofer² in 1817 with far more perfect optical apparatus. He also found similar, but not the same, deficiencies in the light from various fixed stars. The origin of these bands will be explained in RADIATION, along with the theory of their application in spectrum analysis. In optics they are useful to an extreme degree in enabling us to measure refractive indices with very great precision. Wollaston's own account of his discovery is as follows:—

"If a beam of day-light be admitted into a dark room by a crevice $\frac{1}{4}$ th of an inch broad, and received by the eye at the distance of 10 or 12 feet, through a prism of flint-glass, *free from strain*, held near the eye, the beam is seen to be separated into the four following colours only, red, yellowish-green, blue, and violet, in the proportions represented in fig.

"The line A limit bounds the red side of the spectrum is somewhat confused, which seems to result from the want of power in the eye to converge red light. The line B, between red and green, in a certain position of the prism is perfectly distinct, so also the D and E, the two limits of violet. But C, the limit of green and blue, is not so clearly marked as the rest, and there are also on each side of this limit other distinct dark lines *f* and *g*, either of which in an imperfect experiment might be mistaken for the boundary of these colours.

"The position of the prism in which the colours are most clearly divided is when the incident light makes about equal angles with two of its sides. I then found that the spaces AB, BC, CD, DE occupied by them were nearly as the numbers 16, 23, 38, 25."

The mode of formation of a spectrum which was employed by Newton, and which is still used when the spectrum is to be seen by many spectators at a time, differs from that just explained in this, that the light from a source A is allowed to pass through the prism, and to fall on a white screen at a considerable distance from it. In this case the paths of the various rays as they ultimately escape from the prism are found by joining the points *r*, ... *v*, with the prism and producing these lines to meet the screen. Unless one surface of the prism be covered by an opaque plate, with a narrow slit in it parallel to the edge of the prism, the spectrum produced in this way is very impure, *i.e.*, the spaces occupied by the various homogeneous rays overlap one another. To make it really pure an achromatic lens is absolutely requisite. This leads us, naturally, to the consideration of the refraction of light at spherical surfaces.

Refraction at a Spherical Surface.—Following almost exactly the same course as that taken with reflexion above, let O (fig 16) be the centre of curvature of the spherical refracting surface AB. Let U be the point-source of homogeneous light, and let PV be the prolongation (backwards) of the path pursued, after refraction, by the ray UP

Then, *rigorously*, we have

$$\sin UTO = \mu \sin OPV,$$

where μ is the index of refraction between the two media employed. This may be written (by omitting a common factor) as

$$\frac{OU}{UO} = \frac{OV}{VO}$$

It, as before, the breadth of the surface be small compared with its radius of curvature, we may approximate

FIG 16

(sufficiently for many important practical purposes) by writing A for P. Thus we have

$$\frac{OU}{UO} = \frac{OV}{VO}$$

Retaining the same notation as in the case of reflexion, we get

$$\frac{u-r}{u} = \frac{v-r}{v},$$

or

$$\frac{\mu}{v} - \frac{1}{u} = \frac{\mu-1}{r} \quad \dots \dots (1)$$

Notice that, if we put $\mu = -1$, this becomes the formula for reflexion at a concave mirror.

Lenses.—Suppose now that, after passing a *very short* Th distance into the refracting medium, the ray escapes again into air through another spherical surface whose centre of curvature also lies in the line OA. Let *s* be the new radius of curvature, *v* the value of the quantity corresponding to *v* for the escaping ray. Then, remembering that the refractive index is now $\frac{1}{\mu}$, we have (by the previous formula)

$$\frac{1}{\mu} - \frac{1}{v} = \frac{1}{s} - \frac{1}{u},$$

or

$$\frac{1}{v} - \frac{\mu}{s} = \frac{1-\mu}{s} \quad \dots \dots (2)$$

Adding (1) and (2) we get rid of *v*, which indicates the behaviour of the rays in the substance of the lens, and have

$$\frac{1}{w} - \frac{1}{u} = (\mu-1) \left(\frac{1}{r} - \frac{1}{s} \right).$$

This contains the whole (approximate) theory of the behaviour of a very thin lens.

When the source is at an infinite distance, or $u = \infty$, we have

$$\frac{1}{w} = (\mu-1) \left(\frac{1}{r} - \frac{1}{s} \right) \\ = \frac{1}{f} \text{ suppose}$$

This quantity *f*, defined entirely in terms of the refractive index and of the curvatures of the two faces of the lens, is called the *principal focal distance*. If μ be greater than 1, *i.e.*, as in the case of a glass lens in air, *f* is positive if

$$\frac{1}{r} > \frac{1}{s}$$

be so; and it obviously retains the same value, and sign, if the lens be turned round. For, in the formula, *r* and *s* simply change places, and they also change signs; *i.e.*, we must

¹ *Trans. R.S.E.*, vol. III (1791)

² *Gilliet's Analysis*, III

³ "The correspondences of these lines with those of Fraunhofer I have, with some difficulty, ascertained to be as follows:—

A, B, *f*, C, G, D, R, Wollaston's lines
B, D, *b*, F, G, H, Fraunhofer's lines.

There is no single line in Fraunhofer's drawing of the spectrum, nor is there any in the real spectrum, consistent with the line C of Wollaston; and indeed he himself describes it as not being "so clearly marked as the rest." I have found, however, that this line C corresponds to a number of lines half-way between D and F, which, owing to the absorption of the atmosphere, are particularly visible in the light of the sky near the horizon. — Brewster, *Report on Optics*, Brit. Association, 1882

put $-s$ for r and $-r$ for s . This leaves the result unchanged.

All lenses, therefore, whose sections are of any of the forms in fig 16, whichever way they are turned, render

Fig 16

parallel rays which pass through them *diverge*. Their characteristic is that they are thinnest at the middle. But

$$\frac{1}{s} - \frac{1}{s'}$$

is negative for lenses whose sections are of any of the forms shown in fig 17. Such lenses, whichever way they are turned, render parallel rays *convergent*. Their characteristic

Fig 17

is that they are thickest at the middle. But these characters are interchanged when μ is less than 1, as, for instance, when the lens is an air-space surrounded by water. The similarity on reversal is *not* in general true in a second approximation.

The formula for a thin lens now takes the form,

$$\frac{1}{s} - \frac{1}{s'} = \frac{1}{f}$$

and differs from that for a curved reflecting surface only in the sign of the second term. With the proper allowance for this, then, all that we have said of reflection at spherical mirrors holds true of refraction through thin lenses with spherical surfaces.

We may now put the whole matter in the excessively simple form which follows —

A thin lens increases or diminishes by a definite quantity the convergence or divergence of all rays which pass through it.

This quantity is the divergence or convergence of rays falling on the lens from or passing from it to its principal focus. Or it is the convergence or divergence which the lens produces in parallel rays. Thus, if the distance of an object from a convex lens is twice the focal length of the lens, the image is formed at the same distance from the lens, and is equal in size to the object.

Images produced by lenses.

Figs. 18 and 19 show the production of a real image and of a virtual image by lenses which produce convergence of parallel rays—along with the rays by which these are seen by an eye placed behind the lens. In either case it is obvious that the sizes of object and image are, respectively, as their distances from the centre of the lens

Fig. 18 shows how a lens produces a real inverted image (real) of a body placed farther from it than its principal focus. This is the case in the camera obscura, in the solar

Fig 18

microscope, and in the object glass of a telescope. Fig. 19 shows how a virtual image is formed of a body placed nearer to a lens than its principal focus. This is the case of a single lens used as a microscope. In the former case the divergence of the incident rays is so small that the lens renders them convergent. In the latter the divergence is so great that the lens can only diminish, not destroy it.

Fig 19

In using a hand-magnifier in this way, we so adjust it, by practice, that the enlarged image appears to be formed at the distance from the eye at which vision is most distinct. It is obvious that the amount of magnification must, then, be greater as the focal length of the lens is less.

We can now understand the working of the ordinary astronomical telescope (fig 20). The object glass furnishes an inverted but real image of a distant body, *within our reach*. We can, therefore, place the eye-glass (like the single microscope above spoken of) so as to form a virtual magnified image of this real image treated as an object. It is still, of course, inverted. It is easy to see that the

Fig 20

angle subtended at the eye by the virtual image seen through the eye-piece is to that subtended by the object at the unaided eye approximately as the focal length of the object lens is to that of the eye lens. These angles are, in fact, those subtended at the centres of the two lenses by the real image. This ratio is, therefore, called the *magnifying power* of the telescope.

The compound microscope, in its simplest form, is precisely the same arrangement as the astronomical telescope. The only difference is that the object, being at hand, can be placed near to the object-glass (still, however, beyond its principal focus), so that the real image formed is already considerably larger than the object, and is then still further magnified by the eye-glass.

The magnifying power of a single lens, when used as a hand microscope, is to be measured by the ratio of the angle under which the virtual image of an object is seen (at the distance of most distinct vision) to that at which the object itself would be seen (at that same distance), *i. e.*, it is the ratio of 10 inches to the focal length of the lens.

Combinations of Lenses in Contact.—From the formula

$$\frac{1}{f} = (\mu - 1) \left(\frac{1}{r} - \frac{1}{s} \right)$$

we see that the focal length of a simple lens is less as μ is greater. Thus all that we have just said is true for homogeneous light alone. But if we combine two thin lenses, placing them close together, we may arrive at an approximately achromatic arrangement. For we have, for the first lens

$$\frac{1}{w} = \frac{1}{w} - \frac{1}{f},$$

For a second, close to it, we have

$$\frac{1}{x} = \frac{1}{x} - \frac{1}{f'}.$$

For the two, considered as one, we have

$$\frac{1}{x} \frac{1}{u} = \frac{1}{f} + \frac{1}{f'}.$$

Now

$$\frac{1}{f} + \frac{1}{f'} = (\mu - 1) \left(\frac{1}{r} - \frac{1}{s} \right) + (\mu' - 1) \left(\frac{1}{r'} - \frac{1}{s'} \right),$$

and there is an infinite number of ways in which r' and s' can be chosen, when r and s are given, such that the values of the right hand side shall be equal for two values of μ and the corresponding values of μ' . Any one of these gives an achromatic combination, of the necessarily imperfect kind described above in considering prisms. But, as we have now the curvatures of *four* surfaces to deal with, we can adjust these so as not only to make the best attainable approximation to achromatism, but also to reduce the unavoidable spherical aberration to a minimum.

These questions, however, are beyond the scope of this article. We can remark only that the adjustment for two rays, for which the refractive indices are μ and $\mu + \delta\mu$ in the first medium, and μ' and $\mu' + \delta\mu'$ in the second, requires the one relation

$$\frac{\delta\mu}{\mu - 1} \frac{1}{f} + \frac{\delta\mu'}{\mu' - 1} \frac{1}{f'} = 0,$$

which involves only the ratio of the focal lengths of the two lenses—leaving their forms absolutely undetermined. But, if both μ and μ' be greater than unity, the signs of f and f' must be different,—*i. e.*, in an achromatic combination of two lenses one must be convex and the other concave.

The reader must, however, be reminded that we are dealing with a first approximation only, and that spherical aberration does not come in till we reach a second. The details for a proper achromatic combination will be given in OPTICS (GEOMETRICAL).

Before leaving this subject, we must find the behaviour of two thin lenses which are placed at a finite distance from one another. For the first lens we have, as before,

$$\frac{1}{w} = \frac{1}{u} - \frac{1}{f}.$$

If the second lens be placed at a distance a behind the first, the rays which fall on it appear to come from a distance $w + a$. Hence, for the light emerging from the second lens, we have

$$\frac{1}{a} = \frac{1}{w + a} - \frac{1}{f'}$$

When w is infinite, we have from the last two equations

$$\frac{1}{x} = \frac{1}{f} + \frac{1}{f'}$$

It is obvious that a combination of this nature offers the

same kind of facilities for the partial cure of dispersion and of spherical aberration as when the lenses are in contact, with one additional disposable constant. Thus we have compound achromatic eye-pieces, which can be corrected for spherical aberration also.

Formation of a Pure Spectrum.—We may now go back to the formation of an image by a prism, and inquire how, by the use of an achromatic lens, we can project a pure spectrum on a screen. We have seen that a thin prism, for rays falling nearly perpendicular to it, forms a virtual and approximately rectilinear image of a luminous point, in which the colours are ranged in order of refrangibility. Suppose the light which passes through the prism to fall on an achromatic lens, placed at a distance greater than its focal length from the virtual image above mentioned. These rays after passing through the lens will proceed to form, at the proper distance, a real linear coloured image of the luminous point, in which (as in the virtual image) the colours do not overlap. Instead of a luminous point, rays diverging from a very narrow slit parallel to the edge of the prism are employed. It is usual to place the lens at double its focal distance from the virtual image, and thus the real image is formed at an equal distance on the other side of it, and is of the same size. It may now, if required, be magnified by means of an achromatic eye-piece. Or, in other words, it may be examined by means of a telescope. In fact a telescope, whose object glass is covered by a thin prism, has been usefully employed during a total eclipse in examining the light of the solar corona. A similar arrangement, made to have an exceptionally large field of view, is employed to find the nature of the spectra of meteorites or falling stars.

Refraction at a Cylindrical Surface.—A very simple, but interesting, case of refraction at a cylindrical surface is furnished by a thermometer tube. It is easily seen that the diameter of the bore appears, to an eye at a distance large as compared with the diameter of the tube, to be greater than it really is, in the proportion of the refractive index of the glass to unity. Thus in flint glass it appears magnified in about the ratio 5 : 3. Hence the mercury appears completely to fill the external surface of such a tube, if the bore be only $\frac{1}{3}$ ths of the external diameter. But a far more interesting case is that of parallel rays falling on a solid cylinder of glass or water. Its interest consists in the fact that by its aid we can explain the phenomena of the rainbow. We, accordingly, devote special attention to it. The problem, without losing any of its applicability to the rainbow, is much simplified by supposing the rays to be incident in a direction perpendicular to the axis of the cylinder, for in this case the whole course of each ray is in a plane perpendicular to the axis. We need not treat here of rays which pass close to the axis of the cylinder. For such the cylinder acts as a lens, and its focal length (to the usual first approximation) can easily be obtained by methods such as those given above.

What we are mainly concerned with is the behaviour of the rays which escape into the air, after one or two reflexions at the inner surface of the cylinder.

Suppose first that we consider a ray once reflected in the interior of the cylinder. Let SP (fig. 21) be one of the set of incident parallel rays, and let its path be SPQPS'. This involves refraction at P, reflexion at Q, and again refraction

Fig. 21

What we are mainly concerned with is the behaviour of the rays which escape into the air, after one or two reflexions at the inner surface of the cylinder.

Suppose first that we consider a ray once reflected in the interior of the cylinder. Let SP (fig. 21) be one of the set of incident parallel rays, and let its path be SPQPS'. This involves refraction at P, reflexion at Q, and again refraction

Achromatic lenses

tion at P'. But it is obvious from the symmetry of the circular section, and from the laws of refraction and reflection, that this path is symmetrical about the line OQ which joins the axis of the cylinder to the point at which the ray is reflected. Hence SP, SP' meet OQ in the common point s, and the amount by which the direction of the ray has been turned round by the refractions and the reflection is twice the supplement of half the angle at s. But the angle POQ is double OTQ the angle of refraction, while OPs is equal to the angle of incidence. Hence the half angle at s is the excess of twice the angle of refraction over the angle of incidence.

Turn now to fig 22, in which we have two concentric circles whose radii are to one another as the refractive index of the cylinder is to unity. If A be any point on a diameter, and tangents Ap and Aq be drawn from it, we see at once that the sines of the angles at A are to one another as the radii of the circles. Hence, if OAp be the angle of incidence, Oaq is the corresponding angle of re-

function, and it is easy to see that the half angle α (in fig. 22) will in fig. 22 be represented by the *arcus* of OA2 over OA1, α now when OA2 is large, both of these angles are small, and thus their difference is likewise small. As OA becomes less, the difference of the angles becomes greater, but only up to a certain point, for when OA is near the outer circle the angle OA2 begins to increase much faster than does OA1. If hence these A's single definite position of A for which the difference is a maximum. In the first figure these changes in the angles of incidence and refraction, for the members of a group of parallel rays, correspond to the varying positions of P in the circular section of the cylinder. Hence there is one position of P for which the angle α is a maximum. Now one of the conditions of a maximum or minimum of any quantity is that, near it, the value of the quantity *changes very slowly*. Thus a number of issuing rays are crowded together near the direction corresponding to the maximum, the others being more widely scattered,—while for all of them the angle α is a smaller. Newton gives us as an illustration of this, the very slow change of length of the day when the sun is near one of the tropics.

Now suppose the diameter of the cylinder to be small compared with the distance of the eye from it. In this case the point s may be considered as being in the axis of the cylinder.

Let $S\alpha E_1$ (fig. 23) be made equal to the maximum value of α , then an eye placed anywhere in the line αE_1 will receive the rays which are congregated towards the maximum. An eye *within* the angle $S\alpha E_1$ (as at E_2) will receive some

of the straggling rays, while an eye outside that angle (as at E_1) will see nothing. Let there now be imagined a great number of parallel cylinders, let E_1E_2 be drawn parallel to the incident rays, and make the angle $\angle E_1E_2S'$ equal to $\angle E_1E_2S$. Then the eye at E_1 will see the concentrated rays (already spoken of) in the directions E_1E_2 and E_1E_2' . From points within $\angle E_1E_2S'$ some straggling rays will reach it, from wants outside that angle none.

Now suppose cylinders to be placed in great numbers P_1, P_2, P_3, \dots ^{parallel to} $all\ directions$ perpendicular to the incident rays, as in *E*. ^{parallel to} $all\ directions$ *E* we shall see a bright circle of light whose centre is H ^{parallel to} $all\ directions$ in *E*. Inside that circle there will be feeble illumination; ^{parallel to} $all\ directions$ outside it, darkness. This is obviously the case of the rainbow, where we have spherical drops of water instead of the cylinders above spoken of. For each spherical drop is effective only in virtue of a section through its centre, containing the incident ray and the eye, and such sections are the same as those of the cylinders.

Thus far we have been dealing with *parallel* rays of *homogeneous* light, and the appearance (to the degree of approximation we have adopted) is that of a bright circle whose centre is diametrically opposite to the source of light, whose radius is (for raindrops) about $42^{\circ} 2'$, and whose area is slightly illuminated.

Introduce the idea of the different kinds of homogeneous white light which make up sunlight, and we find a circular (almost light-pure) spectrum—the less refrangible rays being on the outside. Next we introduce the consideration of the finite disk of the sun, and we have an infinite series of such arrangements superposed on one another, the centre of each individual of the series being at the point diametrically opposite to the point of the sun's disk which produced it. This leaves the *general* aspect of the phenomenon unchanged, but altogether destroys the purity of the spectrum.

If we next consider light which has been twice reflected within the cylinder, we have a figure like the diagram fig 24, where the lettering is as nearly as possible the

Fig. 22

Fig. 25

Fig. 2

To find it, we have

$$\frac{\pi}{2} - 4\epsilon - 3\mu - \theta,$$

with

$$\sin \theta = \mu \sin \phi.$$

Differentiating, &c., as before, we find

$$8 \cos \theta = \mu - 1,$$

whence, finally,

$$\sin \frac{1}{2}\theta = \frac{\mu^2 + 18\mu^2 - 27}{8\mu^2}.$$

This quantity increases with μ , for its differential coefficient is

$$\frac{1}{8} \left(\frac{9}{\mu^3} - 1 \right)^2,$$

which is necessarily positive (It vanishes, no doubt, for $\mu=3$, but then so does θ).

For $\mu=\frac{4}{3}$ the value of $\sin \frac{1}{2}\theta$ is

$$0.4908 \text{ nearly,}$$

so that

$$\theta = 50^\circ 58'.$$

Second-
ary rain-
bow.

Carrying out the same steps of reasoning as before, and applying the result to raindrops, we find a second rainbow concentric with the first, but with a greater radius, viz., about $61''$ (for yellow light). All the above remarks about the impurity of the spectrum, &c., apply to this bow also. In this bow the less refrangible rays are on the *inner* side, and the straggling rays illuminate feebly the space *outside* it. Hence the space between the red boundaries of the two bows has no illumination from rays reflected either once or twice within the water drops.

What we have now given is nearly all that geometrical optics can tell us about the rainbow. It seems that the first really important steps in the explanation, viz., (1) that the primary bow is due to rays falling on the outer portions of the drops, which suffer two refractions and one reflexion before reaching the eye, and (2) that the secondary bow is due to rays falling on the inner side, and suffering two refractions and two reflexions, are due to Theodorich, about 1811. His work was not published, and its contents were first announced by Venturi¹ in the present century. These results were, independently, discovered by De Dominis² in 1611. Neither of these writers, however, pointed out the concentration of the rays in particular directions. This was done by Descartes in 1637, by the help of Snell's law. He calculated with great labour the paths of each of 10,000 parallel rays falling on different parts of one side of the drop, and showed that from the 8600th to the 8600th the angle between the extreme issuing rays is measured in minutes of arc,—thus discovering by sheer arithmetic the maximum which, as we have seen above, is so easily found by less laborious methods. Newton's addition to this theory consisted mainly in applying his discovery of the different refrangibilities of the different homogeneous rays. The explanation was then thought to be complete. For a long time this was held to be one of Newton's most brilliant discoveries. It is well to notice that he himself speaks of it in its true relation to the work of his predecessors. He merely says,—"But whilst they understood not the true origin of colours, it is necessary to pursue it here a little further." And he said well, for a full investigation conducted on the principles of the undulatory theory introduced, as was first pointed out by Young, certain important modifications in the above statements. Of these we need mention only one, viz., that in each bow there is more than one maximum of brightness for each homogeneous ray. The *spurious* bows, as they are called, which often appear like ripples, inside the primary and outside the secondary bow, and which depend upon the fact just mentioned, have

Spurious
bows.

¹ *Commentarii operis in storia e in teoria dell' Ottica*, Bologna, 1814.

² Newton, in his *Optics*, says the work of De Dominis was written twenty years before it was published.

no place in even Newton's theory. About them, in fact, geometrical optics has nothing to say. Young, in 1804, took the first step for their explanation. They were fully investigated, from the undulatory point of view, by Airy, in 1836-38, and his results were completely verified by the measurements of Hallows Miller in 1841.³ Miller used a fine cylinder of water escaping vertically from a can. This is one of the reasons which induced us to treat the subject as a case of refraction and reflexion in a right cylinder.

The overlapping of the colours in the rainbow, due to the White apparent size of the sun's disk, is occasionally so greatly exaggerated that only faint traces of colour appear. This may happen, for instance, when the sun shines on raindrops in the lower strata of the atmosphere through clouds of ice-crystals in the higher strata. By reflexion from the faces of these crystals, the source of light is spread over a much larger spherical angle, and there is no sharp edge to it as in the case of the unclouded disk. The rainbow is then much broader and fainter than usual, and nearly white. The size of the drops also produces modifications which are not indicated by the geometrical theory.

When the moon is the source of light, the rainbow is so *Lunar* faint that it is often difficult to distinguish the colours; *bow* but with full moon, and other favourable circumstances, it is easy to assure one's self that the colours are really present.

The refraction of sunlight, or moonlight, through ice-Halos, crystals forming cirrus clouds, gives rise to coloured *halos*, *parhelia*, *paraselenae*, &c. Their approximate explanation depends upon the behaviour of prisms with angles of 60° or 90° , and therefore does not come within the scope of the present article. They must not, however, be confounded with *coronae*, those rings which encircle the sun or moon *Coronae* when seen through a mist or cloud. Halos have definite radii depending on the definite angles of ice-crystals; the size of a corona depends on the size of the drops of water in a mist or cloud, being smaller as the drops are larger. Thus their diminution in radius shows that the drops are becoming larger, and implies approaching rain. They are due to *diffraction*, and can only be explained by the help of the undulatory theory.

Refraction in a Non-Homogeneous Medium.—The principles already explained are sufficient for the purpose of *homoe-* treating this question also. But they require, for the *success* application, the artifice of supposing the medium to be made up of layers, in each of which the refractive power is the same throughout the layer, but finitely differs from one layer to another, and then supposing these layers to become infinitely thin and infinitely numerous. In this case there will of course be only an infinitely small difference in properties between contiguous layers; and the abrupt change of direction which accompanies ordinary refraction is now replaced by a *continuous curvature* of the path of the ray.

Glimpses of a more general method had been obtained even in Hamilton's 17th century; and in the 18th these had become a constant *homoe-* process so far as application to the corpuscular theory is concerned, general. But it was reserved for Sir W. R. Hamilton (q.v.) to discover the invest- existence of what he called the *characteristic function*, by the help of *gustions* of which all optical problems, whether on the corpuscular or on the undulatory theory, are solved by one common process. Hamilton was in possession of the germs of this grand theory some years before 1824, but it was first communicated to the Royal Irish Academy in that year, and published in imperfect statements some years later. The following is his own description of it. It is extremely important as showing his views on a very singular part of the more modern history of science.

³ These who have meditated on the beauty and utility, in theoretical mechanics, of the general method of Lagrange, who have felt the power and dignity of that central dynamical theorem which is deduced, in the *Mécanique Analytique*, . . . must feel that mathe-

³ Airy's paper is in vol. vi. of the *Cambridge Phil. Trans.*, Miller's in vol. vii.

metrical optics can only *claim* attain a coordinate rank with mathematical mechanics, when it shall possess an appropriate method, and become the unfolding of a central idea.

It appears that if a general method in deductive optics can be attained at all, it must flow from some law or principle, itself of the highest generality, and among the highest results of induction. . . . (That) must be the principle, or law, called usually the Law of Least Action; suggested by questionable views, but established on the widest induction, and embracing every known combination of media, and every straight, or bent, or curved line, ordinary or extraordinary, along which light (whatever light may be) extends its influence successively in space and time, namely, that the linear path of light, from one point to another, is always found to be such that, if it be compared with the other infinitely various lines by which in thought and in geometry the same two points might be connected, a certain integral or sum, called often *action*, and depending by fixed rules on the length, and shape, and position of the path, and on the media which are traversed by it, is less than all the similar integrals for the other neighbouring lines, or, at least, possesses, with respect to them, a certain *stationary* property. From this Law, then, which may, perhaps, be named the Law of STATIONARY ACTION, it seems that we may most fully and with best hope set out, in the synthetic or deductive process and in the search of a mathematical method.

"Accordingly, from this known law of least or stationary action I deduced (long since) another connected and coextensive principle, which may be called by analogy the LAW of VARYING ACTION, and which seems to offer naturally a method such as we are seeking, the one law being as it were the last step in the ascending scale of induction, respecting linear paths of light, while the other law may usefully be made the first in the descending and deductive way.

"The former of these two laws was discovered in the following manner. The elementary principle of straight rays showed that light, under the most simple and usual circumstances, employs the direct, and therefore the shortest, course to pass from one point to another. Again, it was a very early discovery (attributed by Laplace to Ptolemy), that, in the case of a plane mirror, the bent line formed by the incident and reflected rays is shorter than any other bent line having the same extremities, and having its point of bending on the mirror. These facts were thought by some to be instances and results of the simplicity and economy of nature; and Fermat, whose researches on maxima and minima are claimed by the Continental mathematicians as the germ of the differential calculus, sought analogies to trace some similar economy in the more complex case of refraction. He believed that by a metaphysical or cosmological necessity, arising from the simplicity of the universe, light always takes the course which it can traverse in the shortest time. To reconcile this metaphysical opinion with the law of refraction, discovered experimentally by Snell, Fermat would to suppose that the two lengths, or *indices*, which Snell had measured on the incident ray prolonged and on the refracted ray, and had observed to have one common projection on a refracting plane, are inversely proportional to the two successive velocities of the light before and after refraction, and therefore that the velocity of light is diminished on entering those denser media in which it is observed to approach the perpendicular; for Fermat believed that the time of propagation of light along a line bent by refraction was represented by the sum of the two products, of the incident portion multiplied by the index of the first medium, and of the refracted portion multiplied by the index of the second medium; because he found, by his mathematical method, that this sum was less, in the case of a plane refractor, than if light went by any other than its actual path from one given point to another, and because he perceived that the supposition of a velocity inversely as the index reconciled his mathematical discovery of the minimum of the foregoing sum with his cosmological principle of least time.

Descartes attacked Fermat's opinions respecting light, but Leibnitz zealously defended them; and Saul Huygens was led, by reasonings of a very different kind, to adopt Fermat's conclusions of a velocity inversely as the index, and of a *uniformity* time of propagation of light, in passing from one given point to another through an ordinary refracting plane. Newton, however, by his theory of emission and attraction, was led to conclude that the velocity of light was *directly*, not *inversely*, as the index, and that it was *increased* instead of being *diminished* on entering a denser medium; a result incompatible with the theorem of the shortest time in refraction. This theorem of shortest time was accordingly abandoned by many, and among the rest by Maupertuis, who, however, proposed in its stead, as a new cosmological principle, that *celestial* law of least action which has since acquired so high a rank in mathematical physics, by the improvements of Euler and Lagrange.

"Maupertuis gave the name of *action* to the product of space and velocity, or rather to the sum of all such products for the various elements of any motion,—conceiving that the more space has been traversed and the less time it has been traversed in, the more action may be considered to have been expended, and by combining this idea of action with Newton's estimate of the velocity of light as

increased by a denser medium, and as proportional to the refracting index, and with Fermat's mathematical theorem of the minimum sum of the products of path and indices in ordinary refraction at a plane, he concluded that the course chosen by light corresponded always to the *least possible action*, though not always to the least possible time. He proposed this view as reconciling physical and metaphysical principles which the results of Newton had seemed to put in opposition to each other, and he soon proceeded to extend his law of least action to the phenomena of the shock of bodies. Euler, attached to Maupertuis, and pleased with these novel results, employed his own great mathematical powers to prove that the law of least action extends to all the curves described by points under the influence of central forces; or, to speak more precisely, that if any such curve be compared with any other curve between the same extremities, which differs from it indefinitely little in shape and in position, and may be imagined to be described by a neighbouring point with the same law of velocity, and if we give the same of action to the integral of the product of the velocity and element of a curve, the difference of the two neighbouring values of this action will be indefinitely less than the greatest linear distance (itself indefinitely small) between the two near curves; a theorem which I think may be advantageously expressed by saying that the action is *stationary*. Lagrange extended this theorem of Euler to the motion of a system of points or bodies which act in any manner on each other; the action being in this case the sum of the masses by the foregoing integrals.

"Laplace has also extended the use of the principle in optics, by applying it to the refraction of crystals, and has pointed out an analogous principle in mechanics, for all imaginable connections between force and velocity."

We give, first, a very brief indication of the nature of Hamilton's Varying method, as applicable directly to the corpuscular theory. Here the action of a corporeal is the quantity which possesses the stationary property. Let v be the velocity at any point a, y, s of the medium, ds an element of the path, α, β, γ the direction cosines of ds , which theory are supposed to enter linearly and homogeneously into the expression for v . Then the action V is given by

$$V = \int v ds$$

Hence, for a path nowhere finitely distant from the first,

$$\delta V = - \int (v \delta \alpha + v \delta \beta + v \delta \gamma)$$

But

$$v = \frac{ds}{da} = \frac{ds}{dy} = \frac{ds}{dz} \\ + \frac{ds}{dx} = \frac{ds}{dy} = \frac{ds}{dz} \\ + \frac{ds}{dx} = \frac{ds}{dy} = \frac{ds}{dz}$$

the first three terms depending on the translation of the element ds , the others on its change of direction, and all the differential coefficients being partial. The homogeneity of v gives

$$\frac{dv}{da} + \frac{dv}{dy} + \frac{dv}{dz} = v$$

Also

$$d^2x = d^2y = d^2z = ds \frac{d\alpha}{ds} + ds \frac{d\beta}{ds} + ds \frac{d\gamma}{ds}$$

with two similar equations in y and z .

By the help of these, and a partial integration of the factors $d\alpha, d\beta, d\gamma$, we have

$$\delta V = \frac{dv}{da} \delta a + \frac{dv}{dy} \delta y + \frac{dv}{dz} \delta z \\ + \left[\frac{dv}{d\alpha} \delta \alpha + \frac{dv}{d\beta} \delta \beta + \frac{dv}{d\gamma} \delta \gamma \right],$$

where the integrated part is to be taken between proper limits.

If the initial and final points of the path be fixed, $\delta a, \delta y, \delta z$, vanish in the integrated part, and the stationary condition shows that we must have

$$\frac{dv}{d\alpha} \delta \alpha + \frac{dv}{d\beta} \delta \beta + \frac{dv}{d\gamma} \delta \gamma = 0,$$

with other two similar conditions, only two of the three being independent because of the necessary relation

$$\alpha^2 + \beta^2 + \gamma^2 = 1.$$

These may be regarded as the differential equations of the ray, or path of the corpuscle.

But the essence of Hamilton's method of *varying action* depends upon a change of the terminal point of the ray, and leads at once to the three equations

$$\frac{\delta V}{\delta a} \delta a, \quad \frac{\delta V}{\delta y} \delta y, \quad \frac{\delta V}{\delta z} \delta z,$$

which follow directly from the general value of δV above, by taking account of the vanishing of the unintegrated part in consequence of the stationary condition. We may now write δ for δ everywhere in these expressions

In any isotropic body, homogeneous or not, it is clear that

$$dV = v(dx + ydy + zdz),$$
 and then we have, to determine V , the partial differential equation

$$\left(\frac{dV}{dx}\right)^2 + \left(\frac{dV}{dy}\right)^2 + \left(\frac{dV}{dz}\right)^2 = v^2$$

The treatment of this equation is precisely the same as that of the corresponding one which will presently be derived from the undulatory view of the question

We will now illustrate the application of Hamilton's method to the undulatory theory, in which the *line* of passage from one point of the path to another is the characteristic which fulfils the stationary condition. For the sake of limitation, we will confine ourselves to its application to single refraction in a non-homogeneous medium. In such a medium the velocity of light, at any point, is the same whatever be the direction of the ray. Hence it depends only upon the coordinates of the point, and upon some characteristic (say the wave-length) of the light considered.

If τ be this time of passage, ds an element of the path, and v the velocity of light in that element, we must have

$$\tau = \int \frac{ds}{v},$$

a quantity fulfilling the stationary condition. This gives

$$\delta\tau = \int \frac{dv}{v} - \int \frac{d\tau dv}{v^2}$$

Now, by what has just been said, if λ be the wave-length, we have an equation expressing the data of the problem,

$$v = f(\lambda, x, y, z),$$

where the form of f depends on the arrangement of the parts of the medium. Hence

$$\delta\tau = \int \frac{d\lambda ds + d\lambda dy + d\lambda dz}{vds} - \int \frac{d\lambda}{v^2} \left(\frac{dv}{d\lambda} \lambda + \frac{dv}{dx} x + \frac{dv}{dy} y + \frac{dv}{dz} z \right) - \delta \left[\frac{1}{v} \left(\frac{dx}{ds} \lambda + \frac{dy}{ds} \lambda + \frac{dz}{ds} \lambda \right) \right] - \delta \left[\frac{1}{v} \left(\frac{dx}{ds} \lambda + \frac{dy}{ds} \lambda + \frac{dz}{ds} \lambda \right) \right]$$

The unwritten part consists of an integral which, by the stationary condition, vanishes if the ray be of a definite wave-length and the terminal points through which it passes be given, i.e., if δx , δy , δz , be each equal to 0.

The rest of the expression depends on the terminal points of the ray, and on the wave-length, only. It gives the equations

$$\frac{\delta\tau}{\delta\lambda} = \frac{1}{v} \frac{dv}{d\lambda}, \quad \frac{\delta\tau}{\delta x} = \frac{1}{v} \frac{dv}{dx}, \quad \frac{\delta\tau}{\delta y} = \frac{1}{v} \frac{dv}{dy}, \quad \frac{\delta\tau}{\delta z} = \frac{1}{v} \frac{dv}{dz},$$

and

$$\frac{\delta\tau}{\delta\lambda} = - \int \frac{1}{v^2} \frac{dv}{d\lambda} ds$$

Squaring and adding the last three, we have

$$\left(\frac{\delta\tau}{\delta\lambda}\right)^2 + \left(\frac{\delta\tau}{\delta x}\right)^2 + \left(\frac{\delta\tau}{\delta y}\right)^2 + \left(\frac{\delta\tau}{\delta z}\right)^2 = \frac{1}{v^2}.$$

It is easily shown, by a process similar to that used for *raying action* (see MEMORANDOS), that, if we can find a complete integral of this equation, containing therefore two arbitrary constants, in the form

$$\tau = F(x, y, z, \lambda, a, b),$$

then

$$\frac{\delta\tau}{\delta a} = 2a, \quad \frac{\delta\tau}{\delta b} = 2b$$

are the equations of two series of surfaces whose intersections give the paths of the rays. $2a$ and $2b$ here are the arbitrary constants (These four constants are necessary, and sufficient, for the purpose of making the two intersecting surfaces pass each through any two given points.)

Maxwell's Ray-eye problem. As an illustration, let us suppose the light to be homogeneous, and the medium to be arranged in concentric spherical shells such that the velocity at a distance r from their centre is expressed by

$$v = \frac{b^2 + c^2}{c},$$

where b and c are absolute constants. It is easy to see that, on account of the symmetry, the path of every ray is in a plane through the centre of the spheres. We may therefore restrict our work to the plane of x, y passing through that centre.

The equation is then

$$\left(\frac{dr}{ds}\right)^2 + \left(\frac{dr}{dy}\right)^2 = \frac{c^2}{(b^2 + r^2)^2};$$

or, by change to polar coordinates,

$$\left(\frac{dr}{dr}\right)^2 + \frac{1}{r^2} \left(\frac{dr}{d\theta}\right)^2 = \frac{c^2}{(b^2 + r^2)^2}.$$

What we require is a sufficiently general solution. Assume, therefore,

$$\frac{dr}{d\theta} = a,$$

and we have,

$$\frac{dr}{ds} = \sqrt{\frac{r^2}{(b^2 + r^2)^2} - \frac{a^2}{r^2}}.$$

From these

$$\tau = a\theta + \int dr \sqrt{\frac{r^2}{(b^2 + r^2)^2} - \frac{a^2}{r^2}}.$$

The equation of the path is therefore

$$2a = \frac{dr}{d\theta} = b - c \int \frac{dr}{\sqrt{(b^2 + r^2)^2 - \frac{a^2}{r^2}}},$$

$$= b - c \cos^{-1} \frac{b^2 - r^2}{a^2 - 4b^2 r^2},$$

$$r = \sqrt{\frac{a^2}{a^2 - 4b^2} \cos^2(\theta - 2a)}.$$

or

$$\frac{b^2 - r^2}{r} = \sqrt{\frac{c^2}{a^2} - 4b^2} \cos(\theta - 2a).$$

This is the equation of a series of circles, whose one common characteristic is that the rectangle under the segments of any chord which passes through the origin is b^2 .

Hence every ray in any diaphragm plane describes a circle, and pairs of conjugate foci are situated on a line through the centre, the rectangle under their distances from the centre being b^2 . The property holds therefore for all rays in the medium. This very singular ideal arrangement was suggested to Clerk Maxwell by the eye of a fish. He has given an investigation of it, by a totally different analysis, in the *Cambridge and Dublin Mathematical Journal*, vol. ix. As an illustration of those effects of want of homogeneity to which (as already stated) all the complex phenomena of *mirage*, *haze*, are due, it may be well to consider this simple case more closely. We will therefore consider how images are seen in such a medium. To get rid of the infinity which would arise from finite change of density if an eye was supposed to be plunged in the medium, we will suppose it to be cut across by a crevasse whose surface is everywhere nearly at right angles to the rays by which the image is to be seen,—the eye being then placed (in air) close to such a cutting surface. O the centre of the spherical layers of equal refractive index. Tam every ray from A describes a

circle which passes through A' , where $AOA' = b^2$ is a straight line, and

$$AO \cdot OA' = b^2$$

Annulli construction gives B' from B .

To an eye placed at B_2 (a little crevasse as before explained), and looking towards the object, it will be seen erect,— A being seen in the direction of a tangent to the circle through AE_1A' , and similarly for B . Here the rays have not passed through their conjugate focus. But if the eye be now turned away from the object, it (or rather its image) will be seen, A' in the direction opposite to that in which A was seen, B' in the opposite direction to B . The image will now be an *inverted* one, but it will easily be seen to possess a strange peculiarity. For what is now seen will be the *back* of the object, the side farthest from the eye. The reader may easily trace for himself the course of the rays which would fall on the eye in any other assigned position. Vision in such cases would usually be of a peculiar character from another point of view, viz. the amount of divergence in the plane of the figure will in general differ from that perpendicular to its plane, and therefore the rays would have different divergence for the height and for the breadth of the image. These would therefore appear at different distances from the spectator. This, however, could be cured by a proper cylindrical lens. It is clear from this example (which has been chosen for its special simplicity) that want of

Fig. 25.

homogeneity in a refracting medium is capable of producing phenomena of the most extraordinary character.

Mirage.

It is difficult to ascertain exactly what is the condition of the atmosphere when multiple images, mirage, &c. are seen; and it is obvious from the remarks and illustrations already given that many very different arrangements will produce sensibly the same result to a spectator in a given position. Comparison of the appearances seen simultaneously by a great number of scattered observers is the only way in which we can expect to obtain definite information on such a point. But the following investigation suggests the general nature of the explanation.

If we suppose the refractive index of the air to depend only upon the vertical height above the earth's surface, rays will all travel in vertical planes, and Hamilton's equation (neglecting the curvature of the earth's surface) takes the very simple form

$$\left(\frac{dr}{dz}\right)^2 + \left(\frac{dr}{dy}\right)^2 = f(y),$$

x being measured horizontally, and the refractive index being proportional to $\sqrt{f(y)}$.

This equation gives, as before,

$$r = az + \int dz \sqrt{f(y) - a^2},$$

and the equation of the path of a ray is

$$\frac{dr}{da} = z - a \int \frac{dy}{\sqrt{f(y) - a^2}}.$$

Here, on the corpuscular theory, a is the horizontal velocity of the light, and $\sqrt{f(y)} = a^2$ the vertical velocity. If the form of f and the value of a be such that we can have $f(y) - a^2 = 0$, it is clear that at $y = y_0$ the ray is for a moment horizontal. The form of the equation of the ray shows that it has a vertex at this point, and that it is symmetrical about a vertical axis passing through the vertex. If ξ, η be the coordinates of the vertex for a ray passing through the point $0, \delta$, we have the relation

$$1 = \sqrt{f(\eta)} \int_0^\delta \frac{dy}{\sqrt{f(y) - f(\eta)}}.$$

This is the equation of the locus of the vertices of all rays which, starting from a given point, return again to the same level. To find, then, the various rays by which a distant object near the horizon can be seen, all that we have to do is to draw the curve of vertices which passes through the eye of the spectator, and to find the points in which it is intersected by a vertical line situated midway between the object and the eye. Each of these points is the vertex of a ray by which the object can be seen. When the curve of vertices leans forward towards the eye at one of these points, two conjugate rays cross one another, and an inverted image is seen; when it leans from the eye, they do not cross, and the image is erect.

Now, when the curve of vertices is traced, from the above formula, for an arrangement of the air such that the refractive index falls off through a horizontal stratum of air from a greater value below the stratum to a smaller value above it, it is found that the curve of vertices in the stratum can in general be cut by a vertical line in one point only. But if the refractive index have a nearly stationary value at the upper boundary of the stratum the curve of vertices can be cut twice, or not at all, by a vertical line. When there is no intersection we have only the direct image; but when there are two intersections a distant ship will be seen as usual through the lower uniform air, while there will be seen above it an inverted image, and then a direct image, both due to the stratum. This is a form of mirage very commonly seen at sea. When there is no stationary value of the index at the upper boundary, the upper erect image is not given by the stratum. This arrangement, however, turned upside down, explains the ordinary mirage of the desert—where we see objects directly through the nearly uniform air at some distance above the sand, but also an inverted image (suggesting reflexion from a pool or lake) formed by the reflexion in the hot layer of air near the sand.

Scattering and absorption.

Absorption, Fluorescence.—We must now take up the third and fourth of the categories under which light incident on the bounding surface of two media may fall—*scattering* and *absorption*. We take them together, because in the great majority of bodies, as we have already seen, scattering takes place not merely at the surface but within some distance below the surface, which in general is small, but in some cases considerable. And when the scattering takes place, even in part only, below the surface, the scattered light is usually modified by absorption.

¹ See especially Vince, in the Bakerian Lecture, Phil. Trans., 1796.

An excellent instance of this scattering from below the surface is afforded by a mass of thin films or small particles of transparent bodies, such as glass, water, or ice. Thus pounded glass, froth or foam, snow, clouds, &c., appear brilliantly white in sunlight, and are, in consequence, opaque when in layers of sufficient thickness. Here the light is obviously scattered by reflexion. What passes through one film, crystal, or particle is, in part, reflected from the next, and so on.

Even when the froth consists of bubbles of a highly coloured liquid, such as porter for instance, it usually shows but slight traces of colour, for the great majority of the scattered rays have passed through very small thicknesses only of the liquid. In the same way, very finely pounded blue or red glass (unless it be exceedingly deeply coloured when in mass) appears nearly white. But when a mass of water is full of air bubbles, as, for instance, is the case in the neighbourhood of a breaker, the light of the reflected from the surfaces of these bubbles suffers a double absorption by the water before it reaches the eye. This is one of the causes of the exquisite colours of the sea. Near shore, or in shoal water, another cause sometimes comes into play, viz., fine solid particles suspended in the water. When such particles, whether in air or in water, are exceedingly small, they may produce colours due to their minuteness alone, and not by their own colour nor to the absorptive properties of the medium. This, however, is a question of physical optics.

In general, even the most highly coloured opaque or translucent solids, such as painted wood or stained paper, are visible by scattered light whatever portion of the spectrum falls on them. This is very well seen with highly coloured paper-hangings, when illuminated by homogeneous light, such as that of a sodium flame (a Bunsen flame, into which is thrust a platinum wire dipped in strong brine). The red, orange, and yellow parts usually appear very bright under such treatment, the blue parts appearing but slightly illuminated. The colour of all is, of course, that of the incident light. It appears, therefore, that some of the light is scattered from the surface. It is by this, for instance, that the blue parts are feebly visible. But that which is scattered from the portions coloured red, orange, &c., must come mainly from under the surface.

An excellent proof of this is furnished by mixing, in proper proportions, a yellow and a blue powder, or yellow and blue paints. It is commonly imagined that the green colour which is thus produced is a mixture of blue and yellow. Far from it! When a disk divided into alternate sectors, coloured with the same blue and yellow pigments, is made to rotate rapidly in its own plane, it of course produces on the eye the true result of a mixture of these blue and yellow colours. This depends for its exact tint on the pigments employed, and on the angles of the sectors, but is usually a faint pink or a muddy purple, utterly different from the green produced by mixing the powders or the paints. Helmholtz was the first to point out the true source of the green. It is the *one colour* which is not freely absorbed either by the yellow or by the blue pigment. For the scattered light by which the mixture is seen comes chiefly from below the surface, and has thus suffered absorption by each of the component powders. The yellow powder removes the greater part of the blue, indigo, and violet rays; the blue, the greater part of the reds, oranges, and yellows. Thus the light which finally escapes is mainly green.

For the accurate study of the absorptive power of a solid Exact or liquid medium, it is necessary to compare the spectrum of white light which has passed through a plate or layer of it with a normal spectrum. This is easily effected by placing the absorbing medium (if a fluid, it must be in a

Whiteness of froth, snow, clouds, &c.

sea.

Mixture of pigments.

colours.

study of absorption.

glass (rough with parallel sides) in front of the narrow slit through which the light passes, and in such a position that one half of the slit only is thus covered. We have then side by side, under precisely similar circumstances, two spectra to be compared (one altered by absorption, the other not); and very minute differences between them can thus be detected. When the medium produces a general weakening of the whole spectrum, as well as particular local absorptions, the white light passing through the other half of the slit may be weakened to any desired extent by reflection at the proper incidence from a plate of glass, before it falls on the slit.

To give a satisfactory representation of the phenomena of absorption spectra by the help of a woodcut is not easy. The highest artistic skill could not adequately represent the ordinary solar spectrum by the use of the finest pigments. All optical colour phenomena must be seen, they cannot be reproduced by painting. In such circumstances the simplest method of indicating the locality and amount of the absorption is the best. As we have already seen that we cannot by the eye judge of the relative intensities of lights which differ much in colour, we shall represent the normal spectrum (for our present purpose) as equally bright throughout, and indicate the absorption at different parts by shading of various degrees of depth. A few of the Fraunhofer lines are introduced to indicate (in the absence of colour) the parts of the spectrum which are attacked by the various absorbers. These lines are, of course, in the same absolute positions in all the various spectra, for the spectra are all supposed to be given by the same prism. The line B is in the red, D in the orange, E and F in the green, and G in the indigo. They correspond, as we have already said, to perfectly definite kinds of homogeneous light, and therefore adequately represent the distribution of colours in the spectrum, however much rationally of dispersion may be shown by the material of the prism.

In fig. 26 *a* represents the spectrum of light which has passed through diluted blood; *b* shows the spectrum when the blood has been acted on by a reducing agent, and *c* the spectrum when the blood has been altered by acidulation with acetic or tartaric acid. These figures are taken from an important paper by Stokes (*Proceedings of the Royal Society*, 1864).

Fig. 27 shows in a rude way the absorption by cobalt

Fig. 27

glass cut in wedge form, and corrected by an equal prism of clear glass.

The commonly received method of calculating the absorption by layers of gradually increasing thickness is to

suppose that, if a layer of unit thickness weakens in any ratio the intensity of any particular homogeneous ray, another unit layer will further weaken in the same ratio that which reaches it, and so on. Thus the amount which passes through a number of layers diminishes in geometrical progression, while the number of layers increases in arithmetical progression. This is certainly true (neglecting the amount reflected), unless the intensity of the light have an effect on the percentage transmitted. And fig. 27 shows, in a very striking manner, the difference between similar terms of different geometric series as the common ratio becomes less and less. This ratio is not much less than 1 for certain red and blue rays, is smaller for yellow, and is very small for the rest of the red, for orange, and for green. The latter colours are therefore rapidly got rid of with increasing thickness, then the yellow becomes too feeble to be seen, while, even after the blue becomes almost insensible, the specially favoured red rays are still transmitted in sufficient quantity to be observed.

If x be the fraction of any species of homogeneous light which is transmitted by a layer of unit thickness, that transmitted by a layer of thickness n is x^n . The following little table will greatly assist the reader in understanding the relative rapidity of extinction of different rays passing through various thicknesses of an absorbing medium. It is a table of double entry, the first column giving various values of x , and the upper row various values of n , while the value of x^n is in the same column as that of x and in the same row as that of n .

1	1	0.99	0.9	0.6	0.1
2	1	0.98	0.81	0.25	0.01
5	1	0.951	0.59	0.08	0.0001
10	1	0.904	0.348	0.0059	
100	1	0.360	0.00008		

Thus a ray which loses 1 per cent. in unit thickness still reaches more than 99 per cent. after passing through ten units. But a ray which loses 10 per cent. in the first unit (and which, therefore, will thus far appear scarcely more weakened than the first) is reduced to 35 per cent. by passage through ten units. After passing through a hundred units the first ray has lost only 65 per cent., the second is practically vanishing.

In thin plates cobalt glass is blue, because the particular red which it does not absorb freely forms only a small fraction of the whole transmitted rays; while in thick masses it is nearly red, for then little but this favoured red is transmitted. For a similar reason Condyl's fluid (permanganate of potash) changes its tint in a very singular manner (even when preserved from the action of the air) by gradual dilution with water.

The imperfection of the accommodation of the eye is readily proved by looking through a plate of cobalt glass at a small hole in the window-shutter of a dark room. The hole at first appears red with a blue space round it; but, by an effort of the muscles of the eye, we can see the hole blue, and then there is a red space surrounding it. Rays of so widely different refractive index cannot be seen in focus simultaneously.

Very curious effects are produced when we examine a landscape through such a glass. Foliage of certain kinds scatters scarcely any blue rays, and therefore appears reddish. Bluish greens, again, which scatter very little red, appear blue. The effects may be exaggerated in a very striking degree by combining the absorptions of two or more media, so as to allow of the free transmission of a few, far detached, portions of the spectrum.

Brewster made the very singular discovery that a solution of oxalate of chromium and potash produces one solitary, narrow, absorption band, almost resembling one of the broader lines in the solar spectrum.

Closely connected with intense local absorption in certain parts of the spectrum is the phenomenon of *abnormal dispersion*, one of the most singular discoveries of modern times. It seems to have been first observed by Fox

Talbot; and he discovered its real nature. But the first published notice of such phenomena is due to Le Roux. Christensen and others have since greatly extended our knowledge of the subject, and Helmholtz and Ketteler have given theoretical explanations of it. Fox Talbot's experiment, though the earliest on record, is one of the easiest to perform, and we therefore quote his own account. The experiment was made about 1840, and the following account is from the *Proc. Roy. Soc. Edin.*, 1870-71.

Talbot's
experi-
ment.

"I prepared some square pieces of window glass, about an inch square. Taking one of these, I placed upon it a drop of a strong solution of some salt of chromium, which, if I remember rightly, was the double oxalate of chromium and potash, but it may have been that substance more or less modified. By placing a second square of glass on the first, the drop was spread out in a thin film, but it was prevented from becoming too thin by four pellets of wax placed at the corners of the square, which likewise served to hold the two pieces of glass together. The glasses were then laid aside for some hours until crystals formed in the liquid. These were necessarily thin, since their thickness was limited by the interval between the glasses. Of course the central part of each crystal, except the smallest one, was bounded by parallel planes, but the extremities were bevelled at various angles, forming so many little prisms, the smallest or them floating in the liquid. When a distant candle was viewed through these glasses, having the little prisms interposed, a great number of spectra became visible, caused by the inclined edges. Most of these were no doubt very imperfect, but by trying the glass at various points, some very distinct spectra were met with, and these could with some trouble be isolated by covering the glass with a card pierced with a pin-hole. It was then seen that each prism (or oblique edge of crystal) produced two spectra oppositely polarized and widely separated. One of these spectra was normal; there was nothing particular about it. The colours of the other were very anomalous, and, after many experiments, I came to the conclusion that they could only be explained by the supposition that the spectrum, after proceeding for a certain distance, stopped short and returned upon itself."

Colours
vapour.

Le Roux in 1860¹ discovered that vapour of iodine, which allows only red and blue rays to pass, refracts the red more than the blue. He, like Talbot, did not at first venture to publish his result, and it appeared only in 1863. Among the many convincing proofs of its accuracy he shows that the dispersion by an iodine-vapour prism can be nearly achromatized by a glass prism which gives refraction in the same direction. He also states that the dispersion in iodine-vapour is less as the temperature is higher.

Fuchsma.

Christensen's² earliest determinations were made in 1870 upon an alcoholic solution of fuchsine (one of the powerful aniline colours). This solution gives a dark absorption band in the green; and it was found that the refractive index rises (as in normal bodies) for rays from the red to the yellow. But all the rest of the transmitted light, consisting of the so-called "more refrangible" rays, is less refracted than the red. Kundt and others shortly afterwards greatly extended these observations.

The explanation of this phenomenon, which has been advanced by Helmholtz,³ depends upon an assumption as to the nature of the mutual action between the luminiferous ether and the particles of the absorbing medium, coupled with a further assumption connecting the absorption itself with a species of friction among the parts of each absorbing particle.

In 1879 De Klerker⁴ made a very curious observation, which shows that the whole subject is still obscure. He employed two hollow prisms of equal angle, turned opposite ways, and filled with alcohol. Through such a combination light passes (as we have seen) without refraction or dispersion. When a few drops of the fuchsine solution were added to the contents of one of the prisms, the yellow, orange, and red rays (in the order named) began to separate themselves from the others. This process could be carried on until the solution was so strong that it transmitted no visible light. All this time the blue and violet

rays remained apparently unrefracted—the yellow, orange, and red showing continually increasing refraction. The conclusion from this, on either theory of light, is that the addition of fuchsine to alcohol alters the velocity of propagation of the (so-called) less refrangible rays, but not perceptibly that of the more refrangible.

Fluorescence.—The singular surface appearances presented Fluorescence. by "canary" glass, by some specimens of flint spar, and by certain liquids, such as a solution of sulphate of quinine acidulated with sulphuric acid, had been the source of much speculation long before their true nature was traced by Stokes in 1852.⁵ By a series of well-contrived experiments, one or two of which will presently be described, he put it beyond doubt that the cause of these phenomena lies in a change of refrangibility of the light which has been absorbed by the upper layers of the medium, and is then given off again. In every case the fluorescent light appears to belong to a less refrangible part of the spectrum light, than does the incident light which gave rise to it, thus affording an instance of dissipation, or degradation of energy.

The yellowish-green surface-colour of canary glass (coloured with oxide of uranium) is well known, as the substance is, mainly on account of this property, very commonly used for ornaments. If we admit a ray of sunlight (or light from the electric lamp) into a dark room, through a cobalt glass so dark that the feeble violet-coloured light it transmits is scarcely visible, we find that the canary glass shows its yellow-green colour vividly when placed in the track of the ray. Striking as this experiment is, it is not quite conclusive as to the true cause of the appearance. But if we take another piece of glass, slightly tinged of a brownish-yellow (by oxide of gold), we find that it is quite transparent to the brilliant light from the canary glass; if, however, we place it in the track of the violet rays before they fall on the uranium glass, it prevents the production of the phenomenon altogether. That is, rays which cannot pass through the glass coloured with gold are rendered capable of freely passing through it after incidence on the canary glass. That the phenomenon is due to rays which are stopped by the uranium glass itself is proved by the fact that a second piece of the glass, placed in the track of the rays which have passed through the first, does not show the phenomenon. Unless, indeed, the source of light be very bright, the appearance is confined to a mere surface-layer of the first piece of canary glass. The phenomenon is very well shown by an aqueous infusion of horse-chestnut bark. Some specimens of paraffin oil exhibit it most brilliantly.

To find the rays which are most effective in producing the fluorescence of any substance, we have only to place it in a pure spectrum of sunlight (or, preferably, of the electric light),—prisms and lenses of quartz being used for producing the spectrum, because that material is found to be far less opaque than glass is to the violet and ultra-violet rays. When this is done with uranium glass we find scarcely a trace of effect until the substance reaches the blue rays, and the effect persists through all the higher colours, and even very considerably beyond the bounds of the visible spectrum. Stokes in fact used it as a means of studying the otherwise invisible, but far extending, spectrum of the ultra-violet rays of the electric spark.

The mechanism of the process by which these extraordinary results are produced is still somewhat obscure, and we cannot attempt to explain it here.

The duration of fluorescence is so very short that it is Photo- only by specially devised methods that we can make certain, though it persists for any measurable time after the exciting source.

³ *Phil. Mag.*, xlv, 1874.

⁴ *Comptes Rendus*, 1879.

⁵ *Phil. Trans.*, "On the Change of Refrangibility of Light."

light is cut off from the fluorescent body. Becquerel's ingenious *phosphoscope* was invented for the purpose of inquiries of this kind. It consists essentially of a shallow drum, in whose ends two eccentric holes, exactly opposite to one another, are cut. Inside it are fixed two equal metal disks, attached perpendicularly to an axis, and divided into the same number of sectors, the alternate sectors of each being cut out. One of these disks is close to one end of the drum, the other to the opposite end, and the sectors are so arranged that, when the disks are made to rotate, the hole in one end is open while that in the other is closed, and *vice versa*. If the eye be placed near one hole, and a ray of sunlight be admitted by the other, it is obvious that while the sun shines on an object inside the drum the aperture next the eye is closed, and *vice versa*. If the disks be made to revolve with great velocity by means of a train of toothed wheels, the object will be presented to the eye almost instantly after it has been exposed to sunlight; and these presentations succeed one another so rapidly as to produce a sense of continued vision. By means of this apparatus we can test with considerable accuracy the duration of the phenomenon after the light has been cut off. For such a purpose we require merely to know the number of sectors in the disks and the rate at which they are turned. To guard against deception by the persistence of impressions on the retina, the eye should not be directed fixedly on the object, but should be kept travelling slowly round the position in which it is seen to lie.

Uranium glass shows, with rapid turning, nearly as vivid an effect as when exposed to continuous light, but fades rapidly when the speed of the rotation falls off. A pinkish kind of ruby, exposed to concentrated sunlight in the phosphoscope, is seen to glow with a bright red like a piece of live coal. With very rapid turning, feeble fluorescence can be detected in a great many substances in which the ordinary methods will not show it. This is due in great measure to the fact that the phosphoscope entirely does away with the scattered light, which in the ordinary mode of examining these substances overpowers their feeble fluorescence.

Phosphorescence.

What is correctly termed phosphorescence has nothing to do with phosphorus (whose luminosity in the dark is due to slow oxidation), but it is merely a species of fluorescence which lasts for a much longer time after the excitation has ceased than does that just described. Pliny speaks of various gems which shine with a light of their own, and Albertus Magnus knew that the diamond becomes phosphorescent when moderately heated. But the first discovery of phosphorescent substances, such as are now so common, belongs to the early part of the 17th century. During that century the Bologna stone (sulphide of barium) and Homberg's phosphorus (chloride of calcium) were discovered. Canton's phosphorus (sulphide of calcium) dates from 1768. To the substances mentioned may now be added sulphide of strontium. Any of these sulphides, which must be carefully preserved from the air in sealed glass tubes, appears brilliantly luminous when carried from sunlight into a dark room, and for a long time after presents the general aspect of a hot body cooling. The rays which excite their luminosity are (as with the generality of fluorescent bodies) those of higher refrangibilities; but the colours of the phosphorescent light are of the most varied kind, even in specimens of almost precisely the same chemical composition, but prepared at different times. The causes of this strange diversity are as yet quite unguessed at; but the property has been taken advantage of for the production of what are called *luminous paints*. The behaviour of these substances is one of the most singular phenomena in optics. How they manage to store up so large a supply of energy during a short exposure to bright

Luminous paint.

light, and to dole it out continuously for so long a time and mainly in the form of light, is exceedingly puzzling,—especially as no other physical or chemical change has yet been found to accompany the process. Another curious fact connected with their behaviour was discovered by Becquerel. He found that the less refrangible rays have in some cases the power of arresting the emission of light from these bodies when they have been previously excited by higher rays.

The chemical effects of light will be treated under PHOTOGRAPHY, so far as they are connected with decomposition. Its effects in causing combination, as of hydrogen and chlorine, have already been treated under CHEMISTRY.

UNDULATORY THEORY OF LIGHT.

The explanation of the fundamental laws of Geometrical Optics by the wave-theory requires some preliminary remarks. As the subject will be more fully discussed in a special article, we confine ourselves to what is strictly necessary for the immediate purposes of the present article.

(a) The essential characteristic of wave-motion is that a Wave-disturbance of some kind is handed on from one portion of motion, a solid or fluid mass to another. In certain cases only, this disturbance is unaltered in amount and in kind as it proceeds.

(b) So far as light is concerned, the velocity with which Velocity each particular species of disturbance passes in any direction of propa- gation. is the same for all directions. When the medium is not homogeneous, the velocity may vary from point to point. If the medium be not isotropic, the velocity may depend upon the direction of propagation. Examples of each of these peculiarities will be met with presently.

(c) When two or more separate disturbances simultaneously affect the same portion of a medium, the effect may be very complex. But in the case of light, it has been found that a geometrical (or rather *kinematical*) superposition or composition agrees, at least to the degree of accuracy of the experiments, with all the observed facts. This would be the case, as a dynamical result, if the distortions due to wave-motion were always, even for the most powerful light, exceedingly small. On this is based the whole doctrine of *interference*, Young's grandest contribution to the wave-theory (1801).

(d) The disturbance at any point of a medium, at any *Hy-* instant, is that due to the superposition of all the distur- bances which reached it at that instant from the various sur- roundings parts of the medium. This is (in a somewhat generalized form) what is commonly known as Huygens's principle, first enunciated in 1678.

(e) The front of a wave is defined at any instant as the Wave- continuous locus of all portions of the medium which, at front that instant, are equally and similarly distorted. The word *continuous* is inserted because, in oscillatory wave-motion, such as that of light, a large number of successive waves are exactly equal and similar to one another. Thus we have a *series* of wave-fronts following one another, which are not to be considered as parts of one wave-front. The distance between two successive fronts in which the distortions are similar, measured in the direction in which the light is travelling, is called the *wave-length*.

(f) The colour of homogeneous light depends entirely on Colour the period of a wave, i.e., on the time of passage from one wave-front to the next. This is obviously the same thing as the time of a complete vibration of any one particle of the medium—whatever be the velocity of light in the medium, or the consequent wave-length.

These being premised, let us take the propagation of homogeneous light from a luminous point in a homo-

Wave-
motion,
in homi-
geneous
isotropic
medium

geneous isotropic medium. Here we have simply a succession of concentric spherical wave-fronts, their radii differing by one or more whole wave-lengths. The disturbance in any portion of one of these fronts is propagated radially. But we may consider it from a different point of view, as hinted in (*d*) above. Simple as this particular case is, the reader will probably find that it will greatly assist him in understanding the more complex ones which follow.

Every disturbed portion of the medium may be looked upon as a centre of disturbance from which a new set of spherical waves is constantly spreading. Take then, as common radius, the space described by a disturbance in any very short interval, and, with centres at every point of any one wave-front, describe a series of spheres. The ultimate intersections of these spheres will lie on a surface which is the *envelop* of them all. In the case considered, it is obviously a sphere whose radius exceeds that of the wave-front from which we started by the common radius of the set of spheres. This is shown in a central section in fig 28 below, which suffices to prove that we arrive by this mode of construction at the result which we know in this simple case to be the correct one. It will be seen that the centres of the construction-spheres lie on a certain part of one wave-front, while their ultimate intersections lie on the *corresponding* part of the future wave-front. This holds for spheres of all radii, and for continually increasing radii shows that a plane wave moves perpendicularly to its front. This is so important a part of Huygens's work that we give it in his own words (*Traité de la Lumière*, 1690, pp. 18-20) —

"Pour venir aux propriétés de la lumière, nous suppose premièrement que chaque partie d'onde doit s'étendre en sorte, que les extrémités soient toujours comprises entre les mêmes lignes droites tracées du point lumineux. Ainsi la partie de l'onde *HO*, ayant le point lumineux *A* pour centre, s'étendra en l'arc *CE*, terminé par les droites *AB*, *AD*, *AE*. Car here que les ondes particulières produites par les particules qui composent l'espace *C&E*, se repandent aussitôt de cet espace, toutesfois elles ne concourent point en même instant, à composer ensemble une onde qui termine le mouvement, que précisément dans la circonférence *CE*, qui est leur tangente commune.

"Et d'icy l'on voit la raison pourquoi la lumière, à mesure que ses rayons ne soient réfléchis ou rompus, ne se repand que par des lignes droites, en sorte qu'elle ne balaye aucun objet que quand le chemin depuis sa source jusqu'à cet objet est ouvert suivant de telles lignes. Car si, par exemple, il y avoit une ouverture *BC*, bouchée par des corps opaques *BH*, *GI*, l'onde de lumière qui sort du point *A* sera toujours terminée par les droites *AC*, *AE*, comme il vient d'être démontré. Les parties des ondes particulières, qui s'étendent hors de l'espace *ACE*, étant trop faibles pour y produire de la lumière.

"Or quelques petites que nous fassions l'ouverture *BC*, la raison est toujours la même pour y faire passer la lumière entre des lignes droites, parce que cette ouverture est toujours assez grande pour contenir un grand nombre de particules de la matière éthérée, qui sont d'une petitesse inconcevable, de sorte qu'il parait que chaque petite partie d'onde s'avance nécessairement suivant la ligne droite qui vient du point luisant. Et c'est ainsi que l'on peut prendre des rayons de lumière comme si c'étoient des lignes droites.

"Il paraît en reste, parce qu'il est remarqué touchant la faiblesse des ondes particulières, qu'il n'est pas nécessaire que toutes les particules de l'éther soient égales entre elles, quoique l'égalité soit plus propre à la propagation du mouvement. Car il est très-que l'irrégularité d'un qu'une particule, en poussant une autre plus grande, fasse effort pour reculer avec une partie de son mouvement, mais il ne s'ensuivra de cela que quelques ondes particulières se retirent vers le point lumineux, incapables de faire de la lumière. & non pas d'onde composée de plusieurs, comme estoit *CE*.

"Une autre, et des plus merveilleuses propriétés de la lumière est que, quand il en vient de divers costes, en même d'opposés, elles

font leur effort l'une à travers l'autre sans aucun empêchement. D'où vient aussi que par une même ouverture plusieurs spectateurs peuvent voir tout à la fois des objets différens, et que deux y enoient se voyent en même instant les yeux l'un de l'autre. (Si survient ce qui a été expliqué de l'action de la lumière, et comment ses ondes ne se défont point, ny ne s'interrompent les unes les autres quand elles se croisent, ces effets que je viens de dire sont assez à concevoir. Qui ne le sont nullement à mon avis selon l'opinion de Des-Cartes, qui fait consister la lumière dans une pression continuelle, qui ne fait que tendre au mouvement. Car cette pression ne pouvant agir tout à la fois des deux costes opposés, comme des corps qui n'ont aucune inclination à s'approcher, il est impossible de comprendre ce que je viens de dire de deux personnes qui se voyent les yeux mutuellement, en comment deux même peuvent se pénétrer l'un l'autre."

We will now, for the purposes of this elementary article, assume that something similar holds in all cases, and will not trouble ourselves with the fact that our construction, if fully carried out, would indicate a retrograding wave as well as a progressive one. The obvious fact that a *solitary wave* can be propagated in water, or along a stretched string, may assist the reader in taking the bold step which we have proposed to him. And we will also assume that this mode of representation leads to correct results even when we do not choose a wave-front as the locus of the centres of disturbance,—that in fact we may choose for our purpose *any* surface through which the rays pass, provided always that the radii of the spheres are so chosen that the length of each ray from some definite wave-front to the centre of the sphere, together with the radii of that sphere, always corresponds to a path described in a given time.

We are now prepared to explain the reflexion of light, and we need do so for a plane reflecting surface alone, because the length of a wave, as we shall soon see, is an almost vanishing quantity in comparison with the radius of curvature of any artificial mirror, be it even the smallest visible drop of mercury.

Let a plane wave-front be approaching a plane mirror, and at any instant let fig. 29 represent a section by a plane perpendicular to each, cutting the wave-front in *AB* and the mirror in *AC*. From what has been already said, the motion of every part of *AB* is perpendicular to that line, and in the plane of the figure. During the time that the disturbance at *B* takes to reach *C*, the disturbance which had reached *A* will have (in part, for there is usually a refracted part also) spread back into the medium in the form of a spherical wave whose radius, *AD*, is equal to *BC*. Its section is of course

a circle. That from any other point *P* will have reached *Q*, and then (in part) diverged into a spherical wave whose centre is *Q* and radius $QT(-QT) = BQ - PQ$. Obviously all the circles which can be thus drawn ultimately intersect in the straight line *CD*. This is a section of the reflected wave-front. A plane wave, therefore, remains a plane wave after reflexion, each part of it obviously moves in the plane of incidence, and the similarity of the triangles *ABC* and *CDA* proves the equality of the angles of incidence and reflexion, for the ray is everywhere perpendicular to the wave-front. It is to be particularly noted that this is independent of the velocity of the light, so that all rays are reflected alike. In this, as in the preceding and the immediately following instances, the diagram has been taken (with but slight change) from Huygens.

This being true of any plane wave-front, large or small in area, is necessarily also true of any wave-front of finite

Unobscured
plane
reflexion

Fig. 28

Fig. 29

curvature. Thus, if a set of rays be drawn perpendicular to any wave-front, they will after refraction be perpendicular to a new wave-front; and the lengths of all the rays, from wave-front to wave-front, will be equal.

This is merely another way of stating that if a set of rays can be cut at right angles by a surface (of finite curvature) they will always be capable of being cut at right angles by such a surface, even after any number of reflexions at surfaces of finite curvature, provided they move in a homogeneous isotropic medium.

This proposition will be seen to be capable of extension to reflection, provided always that both media are homogeneous and isotropic. For a plane wave, falling on a plane reflecting surface, our construction (fig 30) is as follows—

Let AB be, as before, a plane wave-front in the first medium, and AC the plane surface of the second medium. As before, let BC be perpendicular to AB. Also let CD be drawn parallel to BA. With centre A and radius AD equal to the space described in the second medium while EC is described in the first, let a sphere be described. The disturbance at A will have diverged in this sphere, while that at B has just reached C. The disturbance at any other point, as P, will have passed to Q, and then have diverged into a sphere of radius QT. Such that

Fig 30

Obviously all spheres so drawn ultimately intersect along CD, which is therefore the front of the refracted wave. The angles of incidence and refraction, being the inclinations of the incident and refracted rays to the normal, are the inclinations BAC and DCA of the incident and refracted wave-fronts to the refracting surface. Their sines are evidently in the ratio of BC to AD, i.e., they are directly as the velocities of propagation in the two media.

Hence the law of refraction also follows from this hypothesis. But there will now be separation of the various homogeneous rays, because the ratio of their velocities in the two media is not generally constant.

Besides, it is clear from the investigation above that, in the refracting medium, the rays are still perpendicular to the wave-front. Thus the proposition lately given may now be extended in the following form—

If a series of rays travelling in homogeneous isotropic media be at any place normal to a wave-front, they will possess the same property after any number of reflexions and refractions. And it is clear from the investigations already given that the time employed by light in passing from one of these wave-fronts to another is the same for every ray of the series.

We now see how crucial a test of theory is furnished by the simple refraction of light. On the corpuscular theory the velocity of light in water is to its velocity in air as 3 : 4 nearly; on the undulatory theory these velocities are as 3 : 4, since, as we have seen, the refractive index of water is about $\frac{4}{3}$. But Foucault's experimental method showed at once that the velocity is less in water than in air. This finally disposed of the corpuscular theory. Though it had been conclusively disproved long before, by certain interference experiments whose nature will presently be described, the argument from this was somewhat indirect and not well suited to convince the large non-mathematical class among optical students and experimenters. The true author of the undulatory theory is

undoubtedly Huygens. Christaldi, Hooke, and others had expressed more or less obscure notions on the subject, but Huygens in 1678 first gave it in a definite form, based to a great extent upon measurements of his own. It was read to the French Academy, but not published till 1800, when it appeared with the title *Traité de la Lumière*. Huygens gives the explanation of the double refraction of Iceland spar, which had been described by Bartholinus in 1670. Unfortunately the remarkable step taken by Newton in explaining the law of refraction on the corpuscular theory—the earliest solution of a problem connected with molecular forces—had for some time been before the scientific world. The authority of Newton was paramount in such matters, and the work of Huygens produced no effect at the time. Even the genius of Young, who at the commencement of the present century recalled attention to this all-but forgotten theory, and enriched it by the addition of the principle of interference, as well as by many important applications, failed to secure its recognition. It was not till 1815 and subsequent years that, in the hands of Fresnel, the undulatory theory finally triumphed, and, even then, the battle was won against determined resistance on the part of the upholders of the corpuscular theory. Witness what Laplace¹ said, in 1817, in the following excerpt from a letter to Young—

"J'ai reçu la lettre que vous m'avez fait l'honneur d. m'écrire, et dans laquelle vous cherchez à établir que, suivant le système des ondulations de la lumière, les sens d'incidence et de réflexion sont en rapport constant, lorsqu'elle passe d'un milieu dans un autre. Quelque ingénieur que soit ce raisonnement, je n'ai pu le regarder que comme un aporie, et non comme une démonstration géométrique. Je persiste à croire que le problème de la propagation des ondes, lorsqu'elles traversent différents milieux, n'a jamais été résolu, et qu'il n'a pu l'être que par les seules méthodes de l'analyse. Des expériences qui ont été faites, et qui ont donné des résultats qui paraissent combats et rejetés par les plus grand nombre des physiciens jusqu'à ce que Newton ait fait voir que ces suppositions résultent de l'action du milieu réfringent sur la lumière, alors on en a eu une explication mathématique du phénomène dans le système de l'émission de la lumière. Ce système qui donne encore l'explication la plus simple du phénomène de l'absorption, que n'explique point le système des ondes lumineuses. Mais les suppositions de Descartes, comme plusieurs aperçus de Kepler sur le système du monde, ont été vérifiées par l'analyse. Mais le monde de la découverte d'une vérité appartient tout entier à celui qui la démontre. Je conviens que de nouveaux phénomènes de la lumière sont jusqu'à présent très difficiles à expliquer; mais en les étudiant avec un grand soin, pour découvrir les lois dont ils dépendent, on parviendra peut-être un jour à reconnaître dans les molécules lumineuses des propriétés nouvelles qui donneront une explication mathématique de ces phénomènes. Remonter des phénomènes aux lois et des lois aux causes, est, comme vous le savez, la vraie marche des sciences naturelles."

Poggendorff remarks that there is no other instance, in the whole history of modern physics, in which the truth was so long kept down by authority. Poggendorff further remarks that of the six chief phenomena of light known in Huygens's time he fully explained three—reflection, refraction, and the double refraction of Iceland spar—at least so far as concerns the direction of the reflected or refracted rays. Phenomena such as diffraction, and the colours of thin plates, required the principle of interference for their explanation, which was first given by Young, and dispersion (not yet quite satisfactorily disposed of) was first accounted for in comparatively recent times by Cauchy. Huygens himself was the discoverer of polarization, but he could not account for it. Even Young also, because like Huygens he supposed the undulations to be in the direction of the ray, failed to account for it, and it was not explained till Fresnel reintroduced with the

¹ Young's Works, ed. by Peacock, vol. i. p. 371. It is matter for curious remark that Laplace refers to Descartes only, and not to Huygens.

most brilliant success a guess of Hooke's (of date 1672), that the vibrations of light in an isotropic medium are perpendicular to the direction of the ray.

Classes of waves.

Taking the undulatory theory as the only one left possible by the experiments of Foucault, we will now consider the explanation it offers of various phenomena. It will be remembered that we have as yet made no assumption whatever as to the precise nature of a wave, and it will be found that a large class of important phenomena can be explained by it without our making any such assumption, but that other classes of phenomena compel us to adopt certain limitations of the very general hypothesis with which we started. As long as we deal with the first class of phenomena, we may take for granted those properties which are common to all ordinary forms of wave motion, such as those in water or air. In ordinary water-waves the motion of a particle is partly to and fro in the direction in which a wave is travelling, partly up and down and therefore perpendicular to that direction. This is obvious to every one who watches a floating cork. In sound-waves, whether in air or in water, the displacement of each particle of the medium is wholly in the direction in which the wave is travelling. Directly connected with this there is another distinction between these classes of waves. In ordinary water-waves the water-elements change only their *form* as the wave passes, in sound-waves there is change of *volume* also. A third distinction, also directly connected with the first, is that sound-waves in water travel at a much greater rate than the swiftest, i.e., the longest, of surface waves.

Interference.

But, in either case, when two similar and equal series of waves arrive at a common point they *interfere*, as it is called, with one another, so that the actual disturbance of the medium at any instant is the resultant of the disturbances which it would have suffered at that instant from the two series separately. Thus if crests, and therefore troughs, arrive simultaneously from the two series, the result is a doubled amount of disturbance. If, on the contrary, a crest of the first series arrive along with a trough of the second, the next trough of the first series will arrive along with the next crest of the second, and so on. One series is then said to be half a wave-length behind the other. In this case, the portion of the medium considered will remain undisturbed. Thus, at the port of

Tide of Batsha.

Batsha in Tong-king, the ocean tide-wave arrives by two different channels, one part being nearly six hours, or half a wave-length, behind the other. As a result, there is scarcely any noticeable tide at Batsha itself, though at places not very far from it the rise and fall are considerable. This was known to Newton, and is noticed by him in the *Principia*, in 24. See also *Phil. Trans.*, vol. xiv. p. 677, for the observed facts and Halley's comments. This also (see ACQUEROS) two sounds of the same wave-length and of equal intensity produce silence if they reach the external ear with an interval of half a wave-length, or any odd multiple of half a wave-length.

Young's discovery.

It is not remarkable that Young's Bakerian Lecture (1801), in which the principle of interference is for the first time described and applied, should consist in great part of extracts from the *Principia*. For there are many passages in Newton's works which might have been written by an upholder of the wave theory. Unaccountably, however, Newton in the context almost always brings in a reference to the "rays of light," as something different from the vibrations of the ether, yet capable of being acted on by them so as to be put into "fits of easy reflexion or of easy transmission." These allusions are the most obscure parts of all Newton's scientific writings; and it is very difficult to form a precise conception of what he meant to express in them.

The following passage, extracted from Young's temperate

reply (*Works*, vol. i. p. 302) to the violent but ignorant assault on him by Lord Brougham in the *Edinburgh Review*, is chosen as showing his own estimate of his own work and of its relation to what was already known —

"It was in May 1801 that I discovered, by reflecting on the beautiful experiments of Newton, a law which appears to me to account for a greater variety of interesting phenomena than any other optical principle that has yet been made known. I shall endeavour to explain this law by a comparison —

"Suppose a number of equal waves of water to move upon the surface of a stagnant lake, with a constant velocity, and to enter a narrow channel leading out of the lake. Suppose then another similar cause to have excited another equal series of waves, which arrive at the same channel, with the same velocity, and at the same time with the first. Neither series of waves will destroy the other, but their effects will be combined: if they enter the channel in such a manner that the elevations of one series coincide with those of the other, they must together produce a series of greater joint elevations, but if the elevations of one series are so situated as to correspond to the depressions of the other, they must equally fill up those depressions, and the surface of the water must remain smooth, at least I can discover no alternative, either from theory or from experiment."

"Now I maintain that similar effects take place whenever two portions of light are thus mixed, and thus I call the general law of the interference of light. I have shown that this law agrees, most accurately, with the measures recorded in Newton's *Optics*, relative to the colours of transparent substances, observed under circumstances which had never before been subjected to calculation, and with a great diversity of other experiments never before explained. This I assert is a most powerful argument in favour of the theory which I had before received: there was nothing that could have led to it in my notion with whom I am acquainted, except some imperfect hints in those unchangeable but neglected notes of nascent inventions, the works of the great Dr Robert Hooke, which had never occurred to me at the time that I discovered the law, and except the Newtonian explanation of the combinations of tides in the port of Batsha."

Young's first application of the principle of interference was made to the colours of *stratified surfaces*, the next to *fringes* the colours of *thin plates*. These, however, are not so *immediately* intelligible as the application to an experiment devised by Fresnel several years later. We therefore commence with Fresnel's experiment, which gives the most simple arrangement yet contrived, but it must be understood that the explanation is really due to Young. BOD (fig 31) is an isosceles prism of glass, with the angle at C very little less than two right angles. A luminous point is

Fig 31

placed at O, in the plane through the obtuse edge of the prism and perpendicular to its base. If homogeneous light be used, the light which passes through the prism will consist of two parts, diverging as if from points O_1 and O_2 , symmetrically situated on opposite sides of the line CO. Suppose a sheet of paper to be placed at A with its plane perpendicular to the line OCA, and let us consider what illumination will be produced at different parts of this paper. As O_1 and O_2 are images of O, crests of waves must be supposed to start from them simultaneously, in homogeneous light. Hence they will arrive simultaneously at A, which is equidistant from them, and there they will reinforce one another. Thus there will be a bright band on the paper parallel to the edges of the prism. If P₁ be chosen so that the difference between P₁O₁ and P₁O₂ is half a wave-length (i.e., half the distance between two successive crests), the two streams of light will constantly meet in such relative conditions as to destroy one another. Hence there will be a line of darkness on the paper, through P₁, parallel to the edges of the prism. At P₂, where O₁P₂ exceeds O₂P₂ by a whole wave-length, we have another

bright band, and at P_2 where O_2P_2 exceeds O_1P_1 by a wavelength and a half, another dark band, and so on. Hence, as everything is symmetrical about the bright band through A, the screen will be illuminated by a series of bright and dark bands, gradually shading into one another. If the paper screen be moved parallel to itself to or from the prism, the locus of all the successive positions of any one band will (by the nature of the curve) obviously be an hyperbola whose foci are O_1 and O_2 . Thus the interval between any two bands will increase in a more rapid ratio than does the distance of the screen from the source of light. But the intensity of the bright bands diminishes rapidly as the screen moves further off, so that, in order to measure their distance from A, it is better to substitute the eye (furnished with a convex lens) for the screen. If we thus measure the distances AP, between A and the nearest bright band, measure also AO, and calculate (from the known material and form of the prism, and the distance OO) the distance O_2O_1 , it is obvious that we can deduce from them the lengths of O_1P_1 and O_2P_2 . Their difference is the length of a wave of the homogeneous light experimented with. Though this is not the method actually employed for the purpose (as it admits of little precision), it has been thus fully explained here because it shows in a very simple way the possibility of measuring a wave-length.

The difference between O_1P_1 and O_2P_2 becomes greater as AP is greater. Thus it is clear that the bands are more widely separated the longer the wave-length of the homogeneous light employed. Hence when we use white light, and thus have systems of bands of every visible wave-length superposed, the band A will be red at its edges, the next bright bands will be blue at their inner edges and red at their outer edges. But, after a few bands are passed, the bright bands due to one kind of light will gradually fill up the dark bands due to another, so that, while we may count hundreds of successive bright and dark bars when homogeneous light is used, with white light the bars become gradually less and less defined as they are farther from A, and finally merge into an almost uniform white illumination of the screen.

In this example, and in all others of a similar character which will be introduced into this elementary article, the solution is only approximate. The utmost resources of mathematics are in most cases required for the purpose of complete solution.

We are now in a position to prove that light moves slower in glass than in air, by the process which was merely indicated while we were discussing the velocity of light. For, if we could slightly lengthen the paths of the rays which come from O_2 , leaving those from O_1 unaltered, the system of bands would obviously be shifted in the direction from A to P in the figure. This happens if a very thin film of glass be interposed in the path of the rays which appear to come from O_2 . The best mode of making the experiment is to put a piece of very uniform plate glass, cut into two parts, between the prism and the screen, so that rays from O_1 pass through one part and those from O_2 through the other. So long as these pieces are parallel, no shifting takes place. But if one be slightly turned, so as to give the rays a longer path through it, the system of bands is at once displaced to the side at which it is situated.

Also, we can now see how it is possible to discover whether light has its velocity affected by that of the medium in which it is traveling. We know that sound travels faster with the wind, and slower against it, than it does in still air. We may, therefore, suppose a disposition of the interference apparatus such that the two rays which interfere have each passed through a long tube full of water. A rapid current may be established, in either

direction, in one or other of the tubes, or in opposite directions in the two, and the shifting of the interference-bands will at once indicate the nature of the effect. We cannot describe the details of the process. The result, however, is analogous to that of wind on sound, but of course very much smaller, and it seems that the actual change of the velocity of light is less than the velocity of the current. See ENRIK.

Let us next consider the effect of a grating, a series of inter-fine parallel wires placed at small equal intervals, or a piece of glass or of speculum metal on which a series of equidistant parallel lines have been ruled by a diamond point. We take only the case in which plane waves of homogeneous light are incident in a direction perpendicular to the plane of the grating, and when the bars and openings of the grating are all equal in breadth.

Consider the effect on an eye or screen at a considerable distance, in the direction BE (fig. 32). If there were no grating, practically no light would reach the eye from the aperture AD unless ABE were very nearly a right angle

Fig. 32

This is, of course, the statement of Huygens already quoted. But Young's principle enables us to say why this is the case. Let us divide AD into a series of equal parts by lines perpendicular to BE, and distant from one another by half a wave-length of the homogeneous light employed. The portions coming to the eye from any two adjacent parts AB, BC will be practically of the same intensity, and will exactly neutralize one another's effects on the eye. For if we take points a and b similarly situated with regard to A and B respectively, the distances of a and b from the eye differ by half a wave-length, and rays from a neutralize those from b. This is true wherever a be taken between A and B. Hence, under the conditions assumed, no light reaches the eye.

Now suppose the alternate parts AB, CD, &c. to be opaque. Similar reasoning will show that the remaining rays conspire to strengthen one another. Thus, when homogeneous light from a distant point falls perpendicularly on a grating in which the breadth of the bars is equal to that of the interstices, it will be seen brightly in a direction inclined at an angle θ (ABE) to the plane of the grating,—the angle θ being such that

$$AC \cos \theta = \text{wave-length}$$

Similar reasoning shows that the light is reinforced whenever θ is such that

$$AC \cos \theta$$

is an integral multiple of the wave-length. The appearance presented when a long narrow slit is the luminous object, and the bars of the grating are placed parallel to it, is therefore (with homogeneous light) a central image with others equidistant from it on each side—their angular distances from it being the values of the angle corresponding to the sizes

$$\frac{\lambda}{a}, \frac{2\lambda}{a}, \frac{3\lambda}{a}, \text{ \&c.}$$

Here λ is the wave-length, and a is the sum of the breadths of a bar and an interstice. It is found in practice, and it is also deducible from the complete

MEASUREMENT
OF WAVE-
LENGTHS

EFFECT OF
WHITE
LIGHT

ADDITIONAL
PROOF
THAT
LIGHT
MOVES
SLOWER
IN GLASS
THAN IN
AIR

theory, that the *ratio* of the breadths of the bar and interstice has but little effect on the result, unless it be either very large or very small. Hence if λ be expressed as a fraction of an inch, and n be the number of lines per inch in the grating, the angular deviations of the bright bands have the sines

$$n\lambda, 2n\lambda, 3n\lambda, \text{ &c.}$$

The mean wave-length of visible rays in air is about $\frac{1}{10000}$ of an inch. Thus a grating with 5000 equidistant lines per inch will give with such light an angular deviation of about 6° for the first bright diffraction line.

If we notice that the sine of the deviation is proportional to the wave-length, it will be obvious that when white light is used the result will be a series of spectra on each side of the central white image, their more refrangible ends being turned towards that image. When the grating is a very regular one, and the appearances are examined by means of a telescope adjusted for parallel rays, the spectra formed in this way show the Fraunhofer lines with as great perfection as do the best prisms. And they have one special advantage, which prisms do not possess. The relative angular separation of the various colours depends solely on their wave-lengths, and thus the spectra formed by different gratings are practically similar to one another. There is, in fact, almost no *irrationality* in this kind of dispersion. In glass prisms and especially in those of flint glass, the more refrangible part of the spectrum is much dilated, while the less refrangible part is compressed.

The counting of the number of lines per inch in a grating is not difficult, nor is the accurate measurement of the angle of deviation of any particular Fraunhofer line. Hence, by the help of the very simple formula given above, the wave-lengths of light corresponding to the various Fraunhofer lines have been determined with very great accuracy from the diffraction spectra of gratings. The following are, according to Angstrom's, a few of the chief values. λ is expressed in ten-millionths of a millimetre.²

A	Atmosphere	7604
B	Atmosphere	6867
C	Hydrogen	6562
D (double)	Sodium	5895
E	Calcium and Iron	5269
F	Hydrogen	4861
G	Iron	4307
H (double)	Calcium and Iron	3968
		3933

For the sake of a discussion to be entered on later, we have appended the refractive index from air into water for each of these rays, as given by Fraunhofer himself.³

If now we suppose AB, CD, &c., to be transparent, while BC, &c., become opaque, it is obvious that the new grating will be the *complement* of the old one, and will give precisely the same appearances at points outside the course of the direct beam. For when there is no grating there is practically no illumination at such points. This statement of course is equally true of any grating, whatever be the ratio of the breadths of the bars to those of the interstices.

Another very curious result of the theory of interference, fully verified by experiment, is furnished by the fact that the *central spot* of the shadow of a small circular disk, cast by rays diverging from a distant point in its axis, is as brightly illuminated as if the disk had not been interposed.

The final example of interference which we can give here is noteworthy on account of a peculiarity which it

presents. Let us consider the case of homogeneous light reflected by a thin plate or film of a transparent material.

Let AB (fig. 33) be the direction of the incident ray, BE the direction in which part of it is reflected to an eye E at a considerable distance: and let DE be the direction in which another part escapes after refraction into the plate at D and partial reflexion at the second surface of the plate at C. Then if Dd be drawn perpendicular to BE, the retardation of the wave in DE as compared with that in DE will be $(2\mu BC - Ed)\lambda$ wave-lengths, where μ is the refractive index to the plate.

Fig. 33

It e' be the angle of refraction, and t the thickness of the plate, it is easily seen that

$$DC \cos e' = t,$$

$$BD = 2BC \sin e' = 2t \tan e'$$

Hence

$$2\mu BC - Dd = 2\mu t \cos e'$$

whenever, for a given thickness of plate, a' is such that

$$2\mu t \cos e'$$

is an integral multiple of λ , the two rays should reinforce one another at E. The same will happen for a given angle of incidence when the thickness of the plate is such that

$$2\mu t \cos e'$$

is an integral multiple of λ . When, on either account $2\mu t \cos e'$ is an odd integral multiple of $\lambda/2$, the rays at E will weaken (perhaps destroy) one another.

Hence, in homogeneous light, a thin plate, tuned about, alternately reflects and does not reflect to an eye in a given position. And a fixed plate of non-uniform thickness reflects light from some parts and not from others. When white light is used there will in general be colours seen which vary with the angle of incidence, and also with the thickness. If the plate is infinitely thin it would appear that there should be infinitely slight retardation only, and the plate should thus be bright in homogeneous light (and of course white in white light) at all incidences.

In general this is not the case. Thus when a soap bubble, or a vertical soap-film, is screened from currents of air, and allowed to drain, the uppermost (i.e., the thinnest) part becomes perfectly black. It can, in fact, be seen only by the feeble light scattered by little drops of oil or particles of soap or dust on its surface. Here, again, Young's sagaciously supplied the germ at least of the explanation. It is given in the following extract from his *Theory of Light and Colours*, the Bakuian Lecture for 1801 already referred to:—

"PROPORTION IV.—If then an undulation arrives at a Surface less of which is the Limit of Mediums of different Densties, a partial halt Effluvia takes place, proportional to the Difference of the wave-lengths."

"This may be illustrated, if not demonstrated, by the analogy of elastic bodies of different sizes. If a smaller elastic body strikes against a larger one, it is well known that the smaller is reflected more or less powerfully, according to the difference of their magnitudes: thus, there is always a reflexion when the rays of light pass from a rarer to a denser stratum of ether, and frequently an echo when a sound strikes against a cloud. A greater body striking a smaller one propels it, without losing all its motion; thus, the particles of a denser stratum of ether do not impart the whole of their motion to a rarer, but, in their effort to proceed, they are recoiled by the attraction of the reflecting substance, with equal force, and thus a reflexion is always secondarily produced, when the rays of light pass from a denser to a rarer stratum." But it is not absolutely necessary to suppose an attraction in the latter case, since the effort to proceed would be propagated backwards without

² *Spectro Scopus*, 1869.

³ As there are nearly 25 millimetres in an inch, these numbers each multiplied by 4 give the wave-lengths approximately in thousand-millionths of an inch.

it, and the undulation would be reversed, a rarefaction returning in place of a condensation; and thus will perhaps be found most consistent with the phenomena."

This idea, of a rarefaction returning by reflexion when a condensation is incident, is equivalent to a loss or gain of half a wave-length when light in a denser body is reflected at the surface of a rarer body. Whether, then, the plate is denser or rarer than the medium surrounding it, one or other of the two interfering rays loses half an undulation more than the other in the mere act of reflexion. This completely removes the difficulty. But Young went farther, and pointed out that if a thin plate be interposed between two media, one rarer, the other denser than the plate, this half wave-length effect should disappear. He verified this conjecture by direct experiment, founded on a modification of a process due to Newton.

Newton's rings. Newton had, long before, devised and carefully employed an excessively ingenious (because extremely simple and effective) method of studying the colours of thin plates. It consisted merely in laying a lens of long focus on a flat plate of glass. The film of air or other fluid between the spherical surface and its tangent plane has a thickness which is directly proportional to the square of the distance from the point of contact. When such an arrangement is looked at in homogeneous light, the lens having been pressed into contact with the flat plate, there is seen a central black spot, surrounded by successive bright and dark rings, whose number appears to be practically unlimited. The radii of the successive bright rings were found by Newton to be as the square roots of the odd numbers 1, 3, 5, &c. Hence the thicknesses of the film of air are directly as these numbers. When rays of higher refrangibility are used the rings diminish in diameter. Hence when white light is employed we have a superposition of coloured rings of all sizes, but it is no longer possible to trace more than four or five alternations of *bright* and *dark* rings—the colours being then more and more compound. This series of coloured rings is named after Newton, and the successive colours, gradually more and more composite, form Newton's *scale of colours*. Thus we read, in books more than thirty years old, of a red or blue of the *third order*, meaning those colours as seen in the third bright ring round the central dark spot.

Many of the most vivid colours of natural and artificial bodies are due to one or other of the forms of interference we have roughly explained. Thus *Borac's buttons* (once employed for ornament as they produce an effect very similar to that of diamonds) were simply polished metal plates stamped by a die of hardened steel, on whose surface a pattern had been engraved consisting of small areas ruled in different directions with close equidistant parallel grooves. That the colours of a pearl and of mother-of-pearl are due to a similar surface corrugation was proved by Brewster, who took impressions from such substances in black wax, and found that it was thus rendered capable of giving the same play of colours. The scales from the wings of butterflies owe their bright colours to a delicate ribbed structure. On the other hand, the thin transparent wings of house-fly, earwig, &c., owe their colour to their thinness. The same is true of the temper colour of steel, Nobil's rings, &c. Very beautiful examples of thin plates scaled off from decayed glass (found in Roman excavations) have been figured, with their play of colours, by Brewster.¹

Here we can only say a word or two about the probable relation between the wave-length of homogeneous light and its refractive index for any isotropic medium. The existence of dispersion was attributed by Cauchy to the fact that even the most homogeneous media, such as water,

have grained or heterogeneous structure of dimensions not incomparably smaller than the average length of a wave of light. This grained structure has been recently proved to exist, by several perfectly independent processes arising from totally unconnected branches of physics; and its dimensions have been assigned, at least in a roughly approximate manner. See ATOM, and CONSTITUTION OF MATTER.

It appears from the theory of disturbances in such a medium that the velocity of a ray depends upon its wavelength in a manner which is expressed by a series of even inverse powers of that wavelength. Hence we have a relation such as

$$\mu = a + \frac{\beta}{\lambda^2} + \frac{\gamma}{\lambda^4} + \dots$$

in which, from our present ignorance of the precise connexion between matter and ether, we must be content to find the multipliers of the various terms by direct measurement. If we neglect all but the first two terms, we may determine α and β from the known wave-lengths of two of Fraunhofer's lines, and their refractive indices for a particular medium. We can then test the accuracy of the formula by its agreement with the corresponding numbers in the same medium for others of the fixed lines. Thus, taking the data for water given above, we have, from the numbers for the two hydrogen lines (C and F, the values

$$\alpha = 1.3243,$$

Calculating from these, and the wave-length of H₁ we have for its refractive index 1.3447, instead of 1.3442 as determined by Fraunhofer. So far as we may trust this theory, which certainly accords fairly with the experimental data for substances of moderate dispersive powers, though by no means well with those for substances of high dispersive power such as oil of cassia, the value of the quantity n is the refractive index for the *longest possible waves*; *i. e.* it is that of the inferior limit of the spectrum.

DOUBLE REFRACTION.—We now come to phenomena which cannot be even roughly explained by processes based on the vague analogies of sound and water waves which have hitherto sufficed for our elementary treatment of the subject.

These phenomena were first observed in Iceland spar. Iceland spar was described in a general way by Bartholinus, who showed that one of the two rays into which a single incident ray is divided by this substance follows the ordinary law of refraction. Huygens, who studied the subject only eight years later, verified the greater part of the results of Bartholinus, and added many new ones. From his point of view it was of course obvious that the ordinary ray is propagated by spherical waves, i. e., its velocity is the same in all directions inside the crystal. To explain the extraordinary ray, he assumed that it was propagated in waves of the form of an ellipsoid of revolution, the simplest assumption he could make. To test the accuracy he first noticed that a rhombohedral crystal of Iceland spar behaves in precisely the same way whichever pair of parallel faces light passes through. Hence he accurately concluded that the axes of the ellipsoids of revolution (if such were the form of the waves for the extraordinary ray) must be symmetrically situated with regard to each of these planes. The only such lines in a rhombohedron are parallel to that which joins those corners which are formed by the meeting of three equal plane angles. In the case of Iceland spar these equal angles are obtuse. Huygens then verified, by experiments well contrived, though carried out by a very rough mode of measurement, the general agreement of his hypothesis with the fact; and he further tested it by comparing its indications as to the position of the two spaces for any position of the crystal

with the results of direct observation. There can be no question that the whole investigation was, for the age in which it was made, of an exceedingly high order. But it must not be left unsaid that far more accurate measurements than those of Huygens were necessary before it could be asserted that the form of the extraordinary wave is an ellipsoid of revolution, and not merely a surface closely resembling such an ellipsoid. These improved measurements were made 1803 by Wollaston, and they have recently been repeated with far more perfect optical means by Stokes, Mascart, and Glaszbrook. The result has been the complete verification of Huygens's conjecture. The generating ellipse of the extraordinary waves is found to have its minor axis, which is that of revolution, equal to the diameter of the corresponding sphere for the ordinary ray. Its major axis is to the minor nearly in the ratio $1.654:1.483$.

We are now in a position to trace the paths of the two rays into which a ray falling in any direction on a surface of the crystal is divided by refraction.

Refraction by Iceland spar.

Let fig. 34 represent a plane wave front AB (in an) falling on the surface AC of a piece of Iceland spar cut in any way. The figure is a section perpendicular to the surface, and parallel to the incident ray. The wave-front AB cuts the surface of the spar in a line (not shown) at right angles to the plane of the paper. Draw from A the axis Aa (not necessarily in the plane of the paper) and the sphere and ellipsoid of revolution which have Aa for a common axis. Then, if C be taken such that BC is to Aa as the velocity of light in air is to that of the ordinary ray in

Fig. 34

the crystal, the wave-front of the ordinary ray is found by drawing a tangent plane to the sphere, passing through C and perpendicular to the plane of the paper. This touches the sphere in a point o (in the plane of the paper) and AoO is the ordinary ray¹. To find the direction of the extraordinary ray, a plane perpendicular to the paper, and passing through C, must be drawn so as to touch the ellipsoid. Let c be the point of contact, which will in general not be in the plane of the paper unless Aa is in or perpendicular to that plane, then AaB is the extraordinary ray.

Thus, in general, the extraordinary ray is not in the plane of incidence. Also the ratio of the sines of the angles of incidence and refraction is generally different for different directions of incidence, in the case of the extraordinary ray.

In an elementary article we cannot attempt more fully to study these phenomena, so we merely state that all the observed appearances, so far as the directions of the

¹ This is merely a repetition of the construction we have already given for singly refracting bodies.

refracted rays are concerned, are explained by supposing the wave-surface in the crystal to be made up of the sphere and the ellipsoid of revolution above described. Thus, when both eyes are used, the two images of a plane object seen through a crystal of Iceland spar appear in general to be situated at different distances above the plane. One of them maintains its apparent position as the crystal is made to rotate about a perpendicular to the two faces employed; the other's position varies as the crystal is turned.

But we have now to inquire *why* the incident ray is divided into two, and why one of them follows the ordinary law of refraction. Here another experimental result of Poisson's comes to our assistance. We paraphrase the author's description:—

"I will, before concluding, mention another remarkable phenomenon which I discovered after the above was written. For, given a diamond I have not yet been able to find the cause of it, I do not dwell on that account to refrain from pointing it out, in order that every one may have an opportunity of seeking to explain it. It appears that it will be necessary to make hypotheses additional to those already given,—though these will lose none of their probability, confirmed as they have been by so many tests. The phenomenon is that, taking two fragments of the crystal (Iceland spar) and laying them on one another, or even holding them apart, if all the faces of the one be parallel to those of the other, a ray of light divided into two by the first fragment will not be further subdivided by the second. The ordinary ray from the first will be refracted ordinarily by the second, the extraordinary ray extraordinarily. And the same thing happens not only in this arrangement but in all others in which the principal sections² of the two fragments are in the same plane, whether the surfaces turned towards one another be parallel or not. It is, in fact, marvellous that these rays, falling on the second fragment, do not divide like the ray incident on the first. One would say that the ordinary ray from the first fragment had lost what is necessary for the production of extraordinary refraction, and the extraordinary ray that which is necessary for ordinary refraction, but there is something else which upsets this view. For when one places the fragments so that their principal sections are straight angles, whether the opposed surfaces be parallel or not, the ordinary ray from the first suffers only extraordinary refraction by the second, and *vice versa*.

"But in all the infinite number of positions other than those named, both rays from the first fragment are divided into two by the second. Thus the single incident ray is divided into four, sometimes equally sometimes unequally bright, according to the varying relative position of the crystals. But all together do not seem to have more light than has the single incident ray.

"When we consider that, the two rays given by the first crystal remaining the same, it depends upon the position of the second crystal whether they shall be divided into two or not, while the incident ray is always divided, it appears that we must conclude that the waves of light which have traversed the first crystal have acquired a form or disposition which in some positions enables them to excite the two kinds of matter which give rise to the two kinds of refraction, in other positions to excite only one of them. But I have not yet been able to find any satisfactory explanation of this."

So far Huygens. His statements are perfectly in accordance with fact, and they were reproduced by Newton³ in very nearly the same form. Newton adds,—"The un-Newton's usual refraction is, therefore, performed by an original property of the rays. And it remains to be enquired, whether the rays have not more original properties than are yet discovered. Have not the rays of light several sides, ended with several original properties?"

It is very curious to notice how near each of these great men came to the true explanation, and yet how long time elapsed before that explanation was found. The date of Huygens's work is 1690, that of Newton's 1704. It was not till 1810 that farther information on the subject was obtained. Then one brilliant observation opened the way for a host of discoveries in a new and immense field of optics.

² Defined as passing through the shorter diagonal of one of the rhombic faces of the crystal, and through the edge formed by the two adjacent faces.

³ *Optics*, Queries 25, 26.

Polarization by reflection.

In the last-mentioned year Malus, while engaged on the theory of double refraction, casually examined through a doubly refracting prism of quartz the sunlight reflected from the windows of the Luxembourg palace. He was surprised to find that the two rays alternately disappeared as the prism was rotated through successive right angles,—in other words, that the reflected light had acquired properties exactly corresponding to those of the rays transmitted through Iceland spar. Even Malus was so imbued with the corpuscular theory of light that he named this phenomenon *polarisation*, holding it as inexplicable on the wave theory, and as requiring a species of polarity (akin to the magnetic) in the light-corpuscles—a close reproduction of one of Newton's guesses.

Transverse vibrations.

But after a short time Hooke's old guess was independently reproduced, and in the hands of Young and others, but most especially of Fresnel, the consequences of the assumption, that the vibrations of the luminiferous medium take place *perpendicularly* to the direction of the ray, were the almost complete explanation of the cause of double refraction, and the discovery (often the prediction) of a long series of the most gorgeous phenomena known to science.

The real difficulty in the way of this conception probably lay in the fact that most of the familiar forms of wave-motion—such as sound-waves in air or in water, and ordinary water waves—are not of this character. In sound-waves the vibrations are wholly in the direction of the ray, while in surface-waves in water they are partly parallel to and partly perpendicular to the direction in which the wave is travelling. That a body may transmit waves in which the vibration is perpendicular to the direction of a ray, it must have the properties of an elastic solid rather than of a fluid of any kind. And our experience of the almost entire absence of resistance to the planetary motion seems, at first sight at least, altogether incompatible with the idea that the planets move in a jelly-like solid, filling all space through which light can be propagated.

Analogies.

Without going into difficult dynamical details, we may obtain a notion of the nature of the motion now to be considered, by observing the propagation of a wave when a long stretched wire or string is struck or plucked near one end. Here the line of motion of each part of the wire is almost exactly perpendicular to the direction of the wire, i.e. to the line along which the wave travels. (When the string is extensible there may be another wave, due to extension; but this, which is analogous to sound, has its vibrations *along* the string, and it usually travels at a very different rate from the other, so that the two are not in any way associated.)

Interference of polarized rays.

Now it is clear that waves of this wholly transverse character can have, in Newton's language, *sides*. And it is also clear that they cannot interfere so as mutually to destroy one another unless their corresponding sides are parallel to one another; nor can they interfere at all if their sides are perpendicular to one another. Hence a very severe test of the theory will be furnished by examining various cases of interference of polarized light, which ought to present in general marked differences from those of ordinary light. It was by experiments of this kind that Fresnel and Arago first firmly established the bases of the theory of polarization. The important fact discovered by Malus was soon generalized into the following statement:—

Polarizing angle.

Light reflected from the surface of substances so different as water, glass, polished wood, &c., at a certain definite angle, which depends on the nature of the substance, is found to possess all the properties of one of the rays transmitted through Iceland spar. If the plane of re-

flexion is parallel to the axis of the spar, the properties of the reflected light are those of the *ordinary* ray; if perpendicular to it, those of the *extraordinary* ray.

It was reserved for Brewster to discover, as the result of an extraordinary series of experimental measurements, the very simple law which follows:—

The tangent of the polarizing angle is equal to the Brewster law refractive index of the reflecting substance.

This may be put in another form, in which its connexion with theory is a little more evident:—

When the reflected ray is completely polarized, it is perpendicular to the refracted ray.

Bearing in mind Huygens's observations on light which has passed through two crystals of Iceland spar, we can now see that a ray of light polarized by reflexion is in general divided into two by a crystal of Iceland spar. But there is only one ray when the principal plane of the crystal is parallel to the plane of reflexion, and none when these planes are perpendicular to one another.

We may now much simplify matters by suppressing the Iceland spar, and using two reflecting plates of glass, so placed that a ray meets each of them in succession at the polarizing angle. It is then found that when the planes of reflexion are parallel the ray is reflected (almost without loss) from the second plate, but when they are perpendicular to one another there is complete extinction.

In intermediate positions the intensity was found by Arago to be as the square of the cosine of the inclination of these planes.

This very simple experiment, which any one may easily make for himself, by putting two pieces of glass at the proper angle in the ends of two wooden tubes which fit into one another, enables us to form a general notion of the modification which is called polarization. The "sides" of the reflected ray are obviously in, and perpendicular to, the plane of incidence; for a ray can be reflected over and over again if the successive planes of incidence are parallel, but is stopped at once if one of them be perpendicular to the others.

Here, however, two new difficulties come in at once:—

(1) Are the vibrations of the reflected ray, in perpendicular to, the plane of reflexion? (2) As ordinary sun or lamp light, reflected at the proper angle from a polarizing surface, shows no variation of intensity when the azimuth of the plane of reflexion is changed, what can be then the direction of its vibrations? These questions have not yet been answered in a thoroughly satisfactory manner.

Many important phenomena are explained in terms quite independent of the proper answer to (1), and, in other words, which do depend on the answer, the theoretical differences between the results of the two hypotheses are so small as to have hitherto remained undetected. In an important test, suggested by Stokes, the experimental results have been at variance in a way not yet explained. It is quite possible that, as is required by Clerk Maxwell's *electromagnetic theory* of light (see *ETHER*), there may be simultaneous displacements, but of different characters, in each of these planes, and then the question would be reduced to—Which of these displacements is the luminous one? But on this theory, both are probably essential to vision.

As to the second question, it may be said—*first*, that, Nature so far as the test of double refraction can inform us, is of completely polarized ray whose plane of polarization is made to rotate rapidly produces precisely the same effects as a ray of ordinary light; and, *secondly*, that, so great is the number of vibrations even of red light in one second, it would be impossible to make the plane of polarization rotate fast enough to affect the circumstances of any of the phenomena of interference, even when they take place between two portions of the same ray, one of which is retarded

thousands of wave-lengths more than the other. But, *thirdly*, the fact that, when homogeneous light is used, Newton's rings have been counted up to the 7000th shows that, whatever be the actual nature of the vibrations of unpolarized light, they must for at least 7000 waves in succession be almost precisely similar to one another. Then, for other 7000 waves or so, we may have a totally different type of vibration. But, *fourthly*, in the course of $\frac{1}{4}$ th of a second, at the very utmost, the vibrations must have been almost uniformly distributed over all directions perpendicular to the ray. Again, however, *fifthly*, another quite different view may be suggested. All common light has its origin from a practically infinite number of sources, consisting of the vibrating particles of the luminous body. The contributions from each of these sources (so far as one definite wave-length is concerned) may be said probably are at any one point as different in direction of vibration as they certainly must be in phase.¹ From this point of view, which we cannot develop here, the uniformity of optical phenomena becomes quite analogous to the statistical species of uniformity which is now found to account for the behaviour of the practically infinite group of particles forming a cubic inch of gas. The reader need only think of the fact that, so numerous are those particles, it is practically (though not theoretically) impossible that even a cubic millimetre of air should, even for $\frac{1}{1000}$ th of a second, contain oxygen particles alone.

Reflexion not at the polarizing angle

Polarization by ordinary refraction

When light is reflected at an incidence either less or greater than the polarizing angle, it behaves as if part of it was only polarized and the rest ordinary light, and it is said to be *partially polarized*. Tested by a crystal of Iceland spar, it gives two images in all positions of the crystal; but their brightness is unequal except in the special positions where they would be of equal brightness were the ray wholly polarized.

From the fourth of the remarks made above regarding common light, and the facts of double refraction, it follows at once that, when light is to any extent polarized by reflexion, there must be an exactly equal amount of polarization must be perpendicular to that of refraction. This was established by experiment soon after Malus's discovery. But as the reflected ray from glass, water, &c., is in general much weaker than the refracted ray, the percentage of polarized light is generally much greater in the former. It was found, however, by experiment that refraction at a second glass plate parallel to the first increases the proportion of polarized to common light in the transmitted ray, and thus that light may be almost completely polarized, by transmission, at the proper angle, through a number of parallel plates. The experimental data of this subject were very carefully obtained by Brewster. He has found, for instance, how the angle of incidence for the most complete polarization varies with the number of plates. The plane of polarization of such a bundle is *perpendicular* to the plane of refraction.

This, however useful on many occasions, is at best a rough arrangement for producing polarized light. By far the most perfect polarizer for a broad beam of light is a crystal of Iceland spar, sufficiently thick to allow of the complete separation of the two rays. But such specimens are rare and costly, so that the polarizer in practical use is now what is called *Nicol's prism*, invented in 1828 (*Jamieson's Journal*, p. 85). By cutting a rhomb of Iceland spar in two, and cementing the pieces together with Canada balsam (after carefully polishing the cut faces),

Nicol's prism.

¹ A curious exception occurs in the case of light reflected from a body which polarizes by absorption. See REFRACTION.

Nicol produced an arrangement in which one only of the two rays is transmitted, the other being totally reflected at the surface of the balsam. The reason is simply that the refractive index of Canada balsam is intermediate to those of the ordinary and extraordinary rays in the spar. The ordinary ray, falling very obliquely on a medium of a smaller refractive index, is totally reflected, the extraordinary ray, falling on a medium of greater, but very little greater, refractive power, is almost wholly transmitted. The only defect of the Nicol's prism is that, to secure the total reflexion, its length must be considerably greater than its breadth; and thus it necessarily limits the divergence of the beam it allows to pass.

Certain doubly refracting crystals exert considerable Polar. absorption on one of the two rays they produce, and can therefore, when in plates of sufficient thickness, be by absorption employed as polarizers. This is the case with some specimens of tourmaline when cut into plates parallel to the axis of the crystal. It is also found in the flat crystals of several artificial salts, such as, for instance, iodo-sulphate of quinine.

Let us now suppose that by one or other of these pieces Two of apparatus, say a Nicol's prism, light has been polarized. Nicol's. If we examine this ray by means of a second Nicol, placed in a similar position to the first, it passes practically unaltered. As the second Nicol is made to rotate, more and more of the light is stopped, till the rotation amounts to a right angle. Two well-constructed Nicols, placed in this position, are practically opaque to the strongest sunlight. During the next quadrant of rotation the transmitted ray gradually increases in brightness, until at 180° of rotation it passes practically unaltered. Precisely the same phenomena occur in the same order during the next half of a complete rotation. The reader will observe that this is merely Huygens's original statement, limited to one of the four rays which are produced by passing common light successively through two crystals of Iceland spar.

Whatever be the true mechanism of polarized light, Symmetry of polarized light. there can be no doubt that its vibrations are *symmetrical* with respect to the ray, and also with respect to the plane of polarization. Hence we may, for many important purposes, symbolize them by simple harmonic vibrations taking place either in or perpendicular to the plane of polarization. But, if they be supposed to take place simultaneously in these two planes, their quality or nature must be essentially different in the two, else the symmetry above referred to would be violated. Hence it will be sufficient for the present to assume that they take place perpendicular to the plane of polarization. The nature of the resulting effects, so far as the eye is concerned, will not be different for the different hypotheses. Also, as no instance has yet been observed, even with the most intense beams of light, in which the joint effects observed are not those due to simple superposition, we may assume that the elastic force of the luminiferous medium, called into play by a displacement, is directly proportional to the displacement, and therefore that the vibrations for each wave-length follow the *simple harmonic law*, that of the cycloidal pendulum.

The subject of the composition of simple harmonic motions of equal period falls to be discussed as an important branch of *kinematics* (see MECHANICS). We will therefore here assume the following results,—referring to the above-quoted article for their proof—

1. Two simple harmonic motions of the same period, in *Proper- lines perpendicular to one another, give, in general, elliptic motion, which may be in the positive or negative direction of rotation.* simple harmonic motion

2. The ellipse becomes a straight line, and the resultant motion therefore simple harmonic, when the phases of the

components are the same, or differ by an integral multiple of π .

3. It becomes a circle when the amplitudes of the components are equal, and then phases differ by an odd multiple of $\frac{1}{2}\pi$. The motion takes place in one direction (say right-handedly) in the circle when this multiplier is 1, 5, 9, 13, &c., and in the opposite (left-handed) when it is 3, 7, 11, 15, &c. . .

Effect of a plate of doubly refracting material

Homogeneous light

Now, suppose a plane polarized ray to fall on a plate of a doubly-refracting crystal (a thin plate of mica or selenite, for instance). Within the plate it will in general be divided into two, which are polarized in planes at right angles to one another. The directions of vibration in these rays are determined by the physical properties of the material. Let them be represented by the lines O*x*, O*y* in fig. 35. Then, if O*A* represents the semiamplitude of vibration in the incident ray, it may be looked on by (2)

above as the resultant of two simple harmonic motions of the same period, whose semiamplitudes are OM and ON, and which are in the same phase. Each of these will pass through the plate of crystal unchanged. But one will, in general, travel faster than the other, for the essential cause of double refraction is the difference of velocities of the two rays. The portions of the two rays which simultaneously escape from the crystal, and which travel together outside it, will therefore differ in phase. Hence, to find the nature of the transmitted light, we must recombine the vibrations in OM, ON, taking account of this difference of phase. By (1) above the result will be in general elliptic motion. The ellipse will necessarily be one of the infinite number which can be inscribed in the rectangle AA'BB', whose construction is obvious. We have then, in general, what is called *elliptically polarized light*. This degenerates (by (2) above) into plane polarized light, whose vibrations are along OA or OA' according as the difference of phase is 0, 2π , 4π , &c. or π , 3π , 5π , &c. And it will become *circularly polarized light* if OM=ON (i.e., if $\angle AOB = \frac{1}{2}\pi$) and the difference of phase be an odd multiple of $\frac{1}{2}\pi$. By (3) above this will be right or left handed, according to the value of the odd multiplier.

Elliptically and circularly polarized light.

This conclusion from the assumption above made is fully borne out by experiment. When a plate of mica, of such a thickness as to retard one of the two rays a quarter of a wave-length more than the other, is interposed between two Nicols, we observe the following phenomena:—

If the Nicols were originally placed so as to extinguish the light, the introduction of the mica plate in general partially restores it. Now, let the mica plate be made to rotate in its own plane. The light vanishes for successive positions, differing by a quadrant of rotation, i.e. whenever the directions of vibration in the crystal coincide with the principal planes of the Nicols. In each of these positions the light from the first Nicol passes unchanged through the mica, and is therefore entirely stopped by the second Nicol. Half-way between these positions the light transmitted through the system is at its brightest, and in these cases it is not altered in brightness by rotating the second Nicol. It is then circularly polarized, and in whatever direction the second Nicol is placed the component of the circular motion which is ready to pass through it is of the same amplitude. Here, then, is a case in which a Nicol (the second) cannot enable us to distinguish between common light and light very seriously modified.

In what precedes, we have assumed that *homogeneous white light* was used. In general, a doubly-refracting plate light produces a difference of phase in its two rays which will depend on their wave-length; and thus when white light is used we have a display of colour, sometimes extremely gorgeous, and we may distinguish light thus circularly polarized from common light by slight changes of colour and intensity as the second Nicol is turned.

Hitherto we have spoken of the polarizing angle for light reflected in air from bodies such as glass, water, &c., which have a higher refractive index than air, and we have seen that an equal amount of light is polarized in the refracted beam. But what if there be no refracted beam? This is the case of total reflexion inside the denser body. Fresnel discovered that in this case the two kinds of polarized light (in planes at right angles to one another) co-exist in the totally reflected ray, but that they differ in phase, and therefore in general recombine into elliptically polarized light. Guided by peculiar theoretical considerations, he was led to construct a piece of glass (*Fresnel's rhomb*), inside which light is twice totally reflected at a certain angle with the result that, if it be originally polarized in a plane inclined at 45° to the plane of reflexion, the emergent light is circularly polarized.

Reflexion from the surface of metals, and of very highly refractive substances such as diamond, generally gives at all incidences elliptically polarized light. Attempts have been made to determine from such effects the refractive indices of metals and other opaque substances. These are all based upon theory, and cannot as yet command much confidence. With certain doubly-refracting substances the light reflected at a definite angle is differently polarized, and sometimes even differently coloured, for different azimuths of the plane of incidence.

When a thin plate of doubly-refracting crystal, which rings gives a bright colour when placed between two Nicols, is and slightly inclined to the ray, the colour changes as the difference of phase of the two refracted rays is increased. If, now, we take a plate of Iceland spar cut perpendicularly to the axis, no colour will be produced by parallel rays passing through it perpendicularly, because both rays have a common velocity parallel to the axis, but, if divergent light be used, there is a gorgeous display of circular coloured rings surrounding the axis, which depends upon the increasing retardation of the ordinary ray behind the extraordinary as their inclination to the axis increases. When the principal planes of the Nicols are at right angles, this system of rings is intersected by two black diameters, in these planes respectively. When the second Nicol is turned through a right angle, we have exactly the complement of the former appearance, i.e., a figure such that, if superposed on the former, it would give an uniform field of white light.

It is to be noticed that none of these phenomena can be observed without the use of the second Nicol. This arises from the fact that, where the vibrations in any direction interfere so as to destroy one another, those in the direction perpendicular to the former interfere so as to strengthen one another. The second Nicol enables us to select one of these portions, and examine it independently of the other.

The only double refraction we have considered particularly is that of Iceland spar, where everything is symmetrical about the axis of the crystal. Such crystals, and they include as a rule all those of the second and third systems in *CRYSTALLOGRAPHY* (q.v.), are called *uniaxial*. Crystals of the first system are not doubly refractive. But it was one of the most valuable of Brewster's discoveries that the great majority of non-isotropic substances are doubly refracting, and in general are *biaxial*, i.e., have two

tion
dup-
to stress

equally important axes inclined to each other at angles of all values from 0° to 90° . The form of the *wave-surface* in such bodies was, at least very approximately, assigned by Fresnel. This forms one of the most brilliant of his many grand discoveries, and it led to Hamilton's prediction of the existence of the two species of *conical refraction*, which was experimentally verified by Lloyd.

Fresnel also made the striking discovery that glass and other simply refracting bodies are rendered doubly refracting when in a state of strain. To this Brewster added the observation that the requisite strain might be produced by unequal heating instead of by mechanical stress, and also that unannealed glass is usually doubly refractive. Clerk Maxwell in 1873 (*Proc. Roy. Soc.*) showed that shearing stress in viscous liquids, such as Canada balsam, renders them temporarily doubly-refractive. This subject has been elaborately investigated by Kundt (*Pogg. Ann.*, 1879).

The details of these subjects, with those of the polarization of light reflected from small particles, the *rotatory polarization* produced by quartz, sugar, transparent bodies under the influence of magnetism, &c., must be deferred to OPTICS (PHYSICAL).

There is, however, one elementary point which must not be omitted here, as it is intimately connected with the wave-theory,—that is, the alteration which light undergoes in consequence of the relative motion of the source and spectator in the line of vision.

Doppler's
principle.

When a steamer is moving in a direction perpendicular to the crests of the waves, she will encounter more of them in a given time if her course is towards them than if she were at rest, while, if she be moving in the same direction as the waves, fewer of them will overtake her in a given time than if she were at rest. The same thing is true of sound-waves. When an express train passes a level crossing at full speed, the pitch of the steam whistle is higher during

the approach and lower during the recess from the listener at the gate than it would be if the engine were at rest. The successive sound-pulses are emitted at the same intervals as before, but from points successively nearer to or farther from the listener. Hence more or fewer reach his ear in a given time. The principle is precisely the same as that of Rømer's observation of the frequency of eclipse of Jupiter's satellites, which we have already given—the number of light-waves which reach the eye per second is increased if the source is approaching, and diminished if it be receding. We are now dealing with a phenomenon which occurs some 600,000,000,000,000 times per second instead of once every forty-two hours. Now, increased wave-frequency, with unaltered velocity of light, certainly implies shorter wave-length and most probably greater refrangibility, and *vice versa*. There is, undoubtedly, a weak link in this reasoning, due to our ignorance of the true nature of the luminiferous medium and of the species of vibration on which light depends. If we knew something definite about the nature of the ether, and the mechanism of its vibrations, this weakness would be at least in part got rid of. Observation has not yet settled the question of the relative motion of bodies, the ether they contain, and the ether in free space.

This principle has been applied with success by Huggins and others to find the rate at which we are approaching to or receding from different fixed stars, and the rate of motion in solar cyclones; and it may even be applied, as was ingeniously suggested by Fox Talbot (*B. A. Report*, 1871), to determine (from the relative velocities of the components of a double star in the line of sight, measured by its aid) the distance of the star itself from our system.

The reader is advised to consult, in connexion with the whole of the second part of this article, the previous article *ETHER*. (P. a. z.)

LIGHTFOOT, JOSEPH (1802-1875), an eminent rabbinical scholar, was the son of Thomas Lightfoot, vicar of Uttoxeter, Staffordshire, and was born at Stoke-upon-Trent in that county, on March 29, 1802. His school education was received at Morton Green near Congleton, Cheshire, and in June 1817 he entered Christ's College, Cambridge, where he made great progress in Latin and Greek, and was reckoned the best orator among the undergraduates. After taking his bachelor's degree, he became for some time assistant master at Repton in Derbyshire, at the canonical age he received ordination, and shortly afterwards was appointed curate of Norton-under-Hale in Shropshire. There he attracted the notice of Sir Rowland Cotton, an amateur Hebraist of some attainments it would seem, who made him his domestic chaplain at Belleport, and was the first to awaken his taste for rabbinical learning. Shortly after the removal of Sir Rowland with his family to London, Lightfoot followed him thither, but for some unexplained reason soon left the capital again, and, visiting his parents at Uttoxeter, took a solemn leave of them, having resolved "to travel beyond the seas." An unexpected and pressing invitation induced him to change his determination, and to accept a charge at Stone in Staffordshire, where he continued for about two years, and where, on May 21, 1828, he married Joyce, daughter of William Crompton of Stone Park, and widow of George Copwood of Delverne, Staffordshire. From Stone he removed to Hornsey near London, for the sake of the library of St. John College, which he often had occasion to consult; his first published work, entitled *Brubins, or Miscellanies, Christian and Judaical, penned for recreation at vacant hours*, and dedicated to Sir R. Cotton, appeared at London in 1829. During the summer

and autumn of 1830 he lived at Uttoxeter, and in September of that year he was presented by Sir R. Cotton to the rectory of Ashley in Staffordshire, where he continued to discharge his pastoral duties, and to prosecute his rabbinical studies, for the next twelve years. For the more uninterrupted pursuit of the latter he is said to have bought a small piece of land near his personage, and to have built upon it a small house "containing a study and withdrawing room below, and a lodging chamber above." "Here he closely followed his said studies with great delight and unwearied diligence, and did choose to lodge here very often, though it were so near to his family and personage house." In June 1842 he left Ashley for London; the precise occasion of the removal is not known, but probably it arose out of the necessity for personal superintendence of the publication of his next work, *A few and new Observations upon the Book of Genesis: the most of them certain; the rest, probable; all, harmless, strange, and rarely heard of before*, which appeared at London in that year with a dedication to "my dear and loving countrymen of the county of Stafford, and other my friends residing in the city of London." Soon after his arrival in the capital he became minister of St Bartholomew's church, near the Exchange; and in 1843 he was appointed to preach the sermon before the House of Commons on occasion of the public fast of March 29. It was afterwards published under the title of *Elihu Redivivus*, the text being Luke i. 17; in it a parallel is drawn between the Baptist's ministry and the work of reformation which in the preacher's judgment was incumbent on the parliament of his own day. Lightfoot was also one of the original members of the Westminster Assembly, which held its first formal meet-

ing on Saturday, July 1, 1643; his "Journal of the Proceedings of the Assembly of Divines from January 1, 1643 to December 31, 1644," now printed in the thirteenth volume of the 8vo edition of his *Works*, is a valuable historical source for the too brief period to which it relates. He was assiduous in his attendance from the first, and, though frequently standing almost or even quite alone, especially in the Erastian controversy, exercised a material influence on the result of the discussions of the Assembly. In 1643 Lightfoot published *A Handful of Gleanings out of the Book of Exodus*, dedicated to the inhabitants of Bartholomew Exchange, and in the same year he was made master of Catherine Hall by the parliamentary visitors of Cambridge, and also, on the recommendation of the Assembly, was promoted to the rectory of Much Munden in Hertfordshire; both appointments he retained until his death. In 1644 was published in London the first instalment of the laborious but never completed work of which the full title runs *The Harmony of the Four Evangelists among themselves, and with the Old Testament, with an explanation of the chief difficulties both in Language and Sense: Part I. From the beginning of the Gospels to the Baptism of our Saviour*. The second part *From the Baptism of our Saviour to the first Passover* after followed in 1647, and the third *From the first Passover after our Saviour's Baptism to the second* in 1650. On August 26, 1646, he again had the honour of preaching before the House of Commons on the day of their monthly fast; in the discourse, which was afterwards published (*A Fast Sermon*, on Rev. xx. 1, 2), after outcountering as erroneous and false the doctrine of the Millenaries, he goes on to urge upon the parliament various practical suggestions for the repression with a strong hand of current blasphemies ("I do hold it a truer point in divinity that 'erroneous conscientia liganda' than 'ligat'"), for a thorough revision of the authorized version of the Scriptures, for the encouragement of a learned ministry, and for a speedy settlement of the church. "I rejoice to see what you have done in platforming classes and presbyteries, and I verily and cordially believe it is according to the pattern in the mount." In the same year appeared *A Commentary upon*

the Acts of the Apostles, chronological and critical, the Difficulties of the text explained, and the times of the Story cast into annals. From the beginning of the Book to the end of the Twelfth Chapter. With a brief survey of the contemporary Story of the Jews and Romans (down to the third year of Claudius), and in 1647 he published *The Harmony, Chronicle, and Order of the Old Testament*, which was followed in 1655 by *The Harmony, Chronicle, and Order of the New Testament*, inscribed to Cromwell, with an epistle dedicatory to his highness's honourable council. In the last-named year Lightfoot, who in 1652 had commenced doctor of divinity, was chosen vice-chancellor of the university of Cambridge, but continued to reside by preference at Munden, in the rectory of which, as well as in the mastership of Catherine Hall, he was confirmed, through the influence of friends, at the Restoration. The remainder of his life was principally devoted to the production of the work by which his name now chiefly lives, the *Horæ Hebrææ et Talmudicæ*, in which the volume relating to Matthew appeared in 1658, that relating to Mark in 1663, and those relating to 1 Corinthians, John, and Luke, in 1664, 1671, and 1674 respectively. Towards the close of 1675, while travelling from Cambridge to Ely (where he had been collated by Sir Orlando Bridgman to a prebendal stall), he caught a severe cold, upon which, by an indiscretion in diet it is said, fever supervened; falling afterwards into a lethargy which continued for about a fortnight, he died at Ely on December 6, 1675. The *Horæ Hebrææ et Talmudicæ impensæ in Acta Apostolorum et in Ep. S. Pauli ad Romanos* were published posthumously.

The *Works of Lightfoot* were first edited, in 2 vols fol., by Bright and Strype in 1844; the *Opera Omnia, cura Tassinii*, appeared at Rotterdam in 1856 (2 vols fol.), and again, edited by Leiden, at Frankfurt in 1869 (3 vols fol.). A volume, *Remarques* was published at London in 1700. The *Hor. Hebr. et Talm.* were also edited in Latin by Carpov (Leipzig, 1675-76), and again, in English, by Gandell (Oxford, 1859). The most complete edition is that of the *Whole Works*, in 18 vols 8vo, edited by Pitman (London, 1828-30). It includes, besides the works already noticed, numerous sermons, letters, and miscellaneous writings; and also *The Temple, especially as it stood in the Days of our Saviour* (London, 1650).

L I G H T H O U S E

I. LIGHTHOUSE CONSTRUCTION.

THE primary and most important consideration relating to the design and construction of a lighthouse tower which is to be built within the tide mark is the force of the waves which may be expected to assail it, and the directions and heights at which that force will act on the building. The great waves which are found in the open ocean cannot be generated in smaller seas, and, with a due regard to economy in construction, ought not therefore to be provided against. What is wanted is to ascertain in such shorter seas the height of waves in relation to the length of "fetch" in which they are generated, and next to determine their energy when on reaching the shore or a sunken rock, and so ceasing to be waves of oscillation, they enormously increase their destructive force by becoming waves of translation. Full information as to these points and as to the marine dynamometer—an instrument used for ascertaining the force of the waves on an exposed surface—will be found in the article *HARBOURS*, to which the reader is referred. It is enough here to state that the law of increase in the height of waves was found by Mr T. Stevenson to be proportional to the square root of the distance from the windward shore, and that the greatest force recorded on rocks exposed to the ocean was $3\frac{1}{2}$ tons per square foot. The relative forces of summer

and winter gales were found to be as 1 to 3, and the vertical force, after acting on a curved sea wall, was eighty-four times greater than the horizontal force at a height of 23 feet above high water.

The history of the ancient lighthouses is of so scanty a nature that we may pass at once to more modern works, commencing with Winstanley's Eddystone Light.

Winstanley's Eddystone Light.—The Eddystone Rocks, which lie about 14 miles off Plymouth, are fully exposed to the south-western seas. The lighthouse was completed by Winstanley in four seasons. In 1698 it was finished at a height of 80 feet and the light exhibited; but in 1699, in consequence of damage by storms, the tower was increased by an outer ring of masonry 4 feet thick, and made solid from the foundation to nearly 20 feet above the rock. The height was increased to nearly 120 feet, and completed in 1700. During the well-known hurricane of 20th November 1703 the tower was destroyed. In general design as well as in details this work must be placed among the *vetanda* of maritime engineering. For example, in plan it was polygonal instead of circular. In his blind devotion to ornamentation Winstanley profaned throughout the principles of uniformity of outer profile so as to present great obstructions to the action of the waves.

Radyer's Eddystone Tower.—This work was commenced

in 1706 and completed in 1709, in the form of a frustum of a cone 92 feet high. The work consisted principally of timber, the lower part being oak carefully bolted together, and also to the rock. Above the lower structure of oak courses of stone, clamped together and fixed to the timber work and to the rock, were added in order to give weight to the structure. This lighthouse stood for forty-six years, and was destroyed by fire in 1755. In every respect the simplicity of the structure and the judicious character of the details of the design may be regarded as models of engineering. First, it rested upon a stepped level base, was circular in plan, did not wholly depend upon fixtures but upon weight, preserved a uniform external surface devoid of outside projections and ornamentation, and, above all, the engineer did not by splaying out the base needlessly throw away the small diameter which the rock afforded, but with much judgment adopted the conical form.

Smeaton's Eddystone Tower.—This justly celebrated work, which consisted entirely of stone, was commenced in 1750, and the masonry was finished in 1759. Smeaton was the first engineer who adopted a structure of masonry for a sea tower and dovetailed joints for the stones, which averaged a ton in weight. This work cannot be regarded as a safe model for general imitation in exposed situations, and Rudyard's earlier tower was certainly as successful in resisting the forces to which it was exposed. Rudyard unquestionably selected for so small a rock as the Eddystone a preferable form to that adopted by Smeaton. The sharply curved profile in Smeaton's design greatly reduced the diameter of the building at a small height above the rock, and so reduced its strength.

Fig 1

Smeaton's reasoning about the similarity of a tower exposed to the surf and an oak tree resisting the wind was very conclusively shown to be fallacious by the late Mr. Alan Stevenson. The arching of the floors, as shown in fig 1, was also a source of weakness which the introduction of the iron chains, shown black in the diagram, was intended to counteract. Mr. Douglass in 1878 stated that "for several years the safety of the Eddystone had been a matter of anxiety and watchful care to the corporation of the Trinity House, owing to the great tremor of the building with each wave stroke." He also stated that the projecting cornice at the top had been lifted, and that the rock itself had been considerably undermined. A new tower has now (1882) been erected in place of Smeaton's by Mr. Douglass.

Bell Rock Lighthouse Tower.—The Bell Rock, which lies 12 miles off the coast of Forfarshire, is fully exposed to the assaults of the German Ocean. The rock is of considerable extent but of a low level, the tower being covered about 16 feet at high water of spring tides. Mr. R. Stevenson, of Edinburgh, when he first landed on the rock, decided to adopt a stone tower as Smeaton had done at the Eddystone, but he deviated largely from that design in the thickness of the walls,

Fig 2

in raising the tower to 100 feet instead of 68 feet, and the level of the solid to 21 feet above high water instead of 11 feet. Instead of employing arched floors as at the Eddystone, he adopted level stones for the floors which formed part of the outward walls, and were feathered and grooved as in carpentry, besides having dovetailed joggles across the joints where they formed part of the walls. It will be seen on fig. 2 that the floors instead of being sources of weakness, as in Smeaton's tower, were converted into effective bonds tying

the walls together. He also used a temporary beacon or barnack on the rock for the engineer and his workmen to live in while the tower was in progress. The bill introduced into parliament for this work in 1802 was not passed in consequence of financial difficulties. As the Bell Rock was scarcely dry at low water, while the Eddystone was scarcely covered at high water, the commissioners, in order to fortify Mr. Stevenson's views, consulted Mr. Telford, and before going to parliament for the second time they also, on Mr. Stevenson's suggestion, obtained for the scheme the support of Mr. Rennie, with whom he could afterwards advise in case of emergency during the progress of the work. The second bill was passed in 1806, and the works, which were begun in 1807, were finished in 1810, and the light was exhibited in 1811. The total weight of the tower is 2076 tons.

Skerryvore Lighthouse.—The Skerryvore Rocks, 12 miles off the island of Tyree in Argyllshire, which is the nearest land, are wholly open to the Atlantic. The works, designed and carried out by the late Mr. Alan Stevenson, were commenced in 1838 and finished in 1843. The first temporary barnack was destroyed in 1838, and another erected on a more sheltered part of the rock. The tower, which is of a hyperbolic curve, is 138 feet high, 42 diameter at the base, and 16 at the top. Its weight is 4308 tons.

Bishop Rock.—The Bishop Rock, lying off the Scilly Islands, is fully exposed to the Atlantic. It was designed by the late Mr. James Walker, and carried out by Mr. J. N. Dorgless. It is 100 feet above high water, 34 feet in diameter at the base, and 17 at the top. The lowest part of the foundation of tower is covered about 19 feet at high water springs, the solid is 20 feet above high water, where the walls are 9 feet thick, and decrease to 2 feet at the top. Owing to the great tremor in this building, it has lately been found necessary to strengthen it by an internal structure of ironwork.

Wolf Rock.—This much exposed rock is about midway between Scilly and the Lizard Point, and is submerged to the depth of about 2 feet at high water. The first design for a lighthouse was in 1823, by Mr. R. Stevenson, but it was not till 1862 that a lighthouse was commenced under the superintendence of Mr. Douglass, from a design by the late Mr. Walker. It is 116½ feet high, 41 feet 8 inches diameter at the base, decreasing to 17 at the top, and the walls are 7 feet 9½ inches thick, decreasing to 2 feet 3 inches. The shaft is a concave elliptical frustum, and contains 3296 tons. The lower part of the tower has projecting acarcments in order to break up the sea, but, as has been already stated in the case of the Eddystone, such projections are not in accordance with the principle of uniformity of external surface, and are, therefore, more likely to produce disturbance of the masonry than to add to its stability.

Dhu Heartach Rock Lighthouse.—The Dhu Heartach Rock, which is 35 feet above high water, is 14 miles from the island of Mull, which is the nearest shore. The maximum diameter of the tower, which is of parabolic outline, is 36 feet, decreasing to 16 feet; the shaft is solid for 32 feet above the rock, the masonry weighs 3115 tons, of which 1810 are contained in the solid part. The temporary barnack for the workmen was made of malleable iron bars with an iron drum on the top in which the workmen lived. This tower was designed by Messrs D. & T. Stevenson, and occupied six years in erection, the length of the working season being only about two and a half months in each year.

Chickens Rock Lighthouse.—The Chickens Rock lies 1 mile off the Caif of Man. The curve of the tower, which is 123 feet 4 inches high, is hyperbolic, the diameter varying from 12 feet to 16 feet. The tower is submerged 5 feet at

high-water springs. The solid is 32½ feet in height, weighing 2050 tons, the whole weight of the tower being 3557 tons. The walls decrease from 9 feet 3 inches to 2 feet 3 inches in thickness. The work was designed by Messrs D & T Stevenson, and was begun in 1860 and completed in 1874.

Great Basses Lighthouse near Ceylon—Great Basses lighthouse has 6 miles from the nearest land, and was designed by Mr. Deanglass. The tower has a cylindrical base 32 feet in diameter, above which is a tower 67 feet 5 inches high and 93 feet in diameter. The walls vary in thickness from 5 feet to 2 feet. The tower, including the base, contains about 2768 tons, and the work was finished in three years.

There are several other lighthouses in Ireland, India, and America which merit more attention than our space admits of, and we shall therefore conclude with directing the attention of the engineer to the important influence of the configuration of rocks in modifying the breaking of waves. It cannot but excite surprise that some of the structures which were erected on the Eddystone should have withstood the waves so long as they did. This fact seems to lead to the conclusion that the Eddystone Rock, at one time at least, acted to some extent as a shelter to the structures which were built on it. During a summer gale when Dhu Heantach lighthouse was being erected fourteen stones each of 2 tons weight, which had been fixed on the tower by joggles and Portland cement at the level of 37 feet above high water, were torn out and swept off into deep water, as shown on Plate VII. At the Bell Rock stones of 2 tons weight were several times swept away during the construction of the tower, while it is a remarkable fact that no stones were ever moved at the Eddystone. But what is more striking, the thin glass panes of Winstanley's first tower stood successfully through a whole winter's storms at the same level above the water as that at which the fourteen heavy blocks were swept away at Dhu Heantach, while it was found necessary from the experience acquired when constructing the lighthouse to raise the solid base of the tower to nearly the same height above the water as the glass panes in Smeaton's tower, which have hardly ever been broken during the storms of more than a hundred years.

The conclusion then which seems fairly deducible from these facts is that the level of the plane of dangerous impact of the waves above high water depends upon the relation subsisting between their height and the configuration of the rocks above and below high water, as well as perhaps on the configuration of the bottom of the sea near the lighthouse. Thus, while the rock at Dhu Heantach, from its height above high water, forms a great protection against the smaller class of waves, it operates as a dangerous conductor to the largest waves, enabling them to exert a powerful horizontal force at a much higher level than they would had the rock been lower. The lighthouse engineer must therefore beware of taking it for granted that Smeaton's Eddystone tower is a model for general imitation, and must carefully consider as best he can in what way the configuration of the rock may affect the stability of the tower which he has to design. Unfortunately in the present state of our information no specific directions can be laid down for his guidance in this matter, but the following general rules of construction may be given.—

(1) The tower should have a low centre of gravity and sufficient mass to prevent its being upset by the waves. (2) It should be throughout regular in the horizontal plane, and either straight or continuously curved in the vertical plane, so as to present no abrupt change of outline which would check the free ascent of the rising waves, or the free descent of the falling waves, or the free vent of those passing round the tower. All external ornaments in the vertical plane, or polygonal outline in the horizontal plane,

are therefore objectionable. (3) Its height, *ceteris paribus*, should be determined by the distance at which the light requires to be seen by the sailor. The rule for determining this height will be afterwards given. (4) Where the rock is soft, or consists of ledges which are easily torn up, the tower should spring from the foundation-course at a low angle with the surface of the rock, so as to prevent its being broken up by reaction of the waves from the building, or, in other words, the tower must have a curved profile. But special care should be taken to sink the foundation-course below the surface of the rock, as the superimposed weight decreases with the sine of the angle of inclination of the wall. If the rock overhangs, owing to the wearing action of the waves, the tower should, if possible, be built at a distance from the place where this dangerous action is in progress. (5) Where the rock is hard and of ample area, the tower may be of such a curved form as will best suit the economic arrangement of the masonry, so as to avoid an unnecessary thickness of the upper walls. (6) When the rock is hard, but of small dimensions, the diameter above the base should not be suddenly reduced by adopting a curved profile, but a conical outline should be adopted, and if the rock be hard, but of yet smaller dimensions, a cylindrical form of greater height should be adopted so as to thicken the walls, and to increase the weight and therefore increase the friction, which is directly proportional to the weight of the blocks of masonry. In all cases where the rock is small the thickness of the walls should be decreased by steps or saucerments *ceteris paribus*, but never *extremely*. (7) The level of the top of the solid part of the tower, and the thickness of the walls above it, should, in different towers having the same exposure, be determined in each case by the level and configuration of the rock and of the bottom of the sea. (8) The best position for the tower is not necessarily the highest part of the rock. It should, in each case, be selected so as to secure the greatest protection in the direction of the maximum fetch and deepest water near the reef. (9) The tower should not, if possible, be erected across any chasm which divides the rock, or in the direction of any gully which projects into it, especially if it be of converging form, which would concentrate wave action. (10) No permanent fixture of the tower to the rock is required for increasing the stability of the structure. The foundation-course (unless where a curved profile is adopted) becomes, indeed, in the end the most stable of all, because it has the greatest weight above it, to keep it in its place. (11) The stones should, however, be sufficiently connected together and fixed to the rock, in order to prevent their being washed away during the construction of the work, when they have no superimposed weight to keep them in their beds. (12) The tower should rest on a truly level base, or on level steps cut in the rock. (13) The pressure of all the materials within the tower should act vertically, so as not to produce a resolved force acting laterally as an outward thrust. (14) The tower should be of such height and diameter, with walls of such thickness, as to prevent the masonry being disturbed by the impact of the waves. (15) The entrance door should be placed on that side of the tower where the length of fetch is shortest, or where from the configuration of the reef and the depth of water, the force of the waves is least. This was determined at the Bell Rock by the distribution of the *fucos* which grew on the lower parts of the tower during the first winter, the vegetation being least where the waves were heaviest. (16) The materials should be of the highest specific gravity that can be readily obtained, and, in some special cases, lead, or dove-tailed blocks of cast iron set in cement, might perhaps be employed.

Plate VII. shows sections on the same scale of a number of the more remarkable lighthouse towers.

Fig. 3 shows an iron pile light erected at Hameda, in the Bay of Yedo, Japan.

Fig. 3

Modes of Uniting the Stones and Courses of Masonry.—Fig. 4 (p. 618) shows the mode of combining the stones during construction at different lighthouses in the United Kingdom and in America.

II LIGHTHOUSE ILLUMINATION

What is required of every lighthouse apparatus is either the equal distribution of the rays constantly or periodically over the whole horizon, or else their unequal distribution over certain azimuths only.

The first of these two cases, viz., the equal distribution of the light, will be best understood by explaining the different manner in which the rays are operated on by the apparatus for a fixed light and by that for a revolving light. The characteristic of a *fixed* light, which is that of being seen constantly and always of the same power round the whole horizon, might no doubt be perfectly produced by a naked flame without any apparatus, but then all the rays which did not fall on the navigable track of shipping would be lost to the sailor. In order then to intercept and utilize those rays which, instead of falling on this navigable track, would either go upwards to the sky or downwards on the shore close to the lighthouse tower, and on that part of the sea which is very near the shore, we must have recourse to optical agents both for bending down the rays which naturally point too high, and for bending up those which point too low. It thus appears that the apparatus for a fixed light should bend the rays in the vertical plane only, but should not interfere with their natural horizontal divergence in azimuth.

The demands which are made on a light that has to *revolve* are not nearly so great as on one that is fixed, for the revolving light does not, like the fixed, require to illuminate the whole horizon simultaneously, but only each point of it at successive intervals of time. When the dark intervals occur, the rays from the flame which are then pointing in the direction of the dark spaces should therefore have their directions so altered laterally as to pass into the adjoining light spaces and thus to increase the power of the luminous flashes. A revolving light, though supplied by a flame of the same power as a fixed, will thus necessarily be far more intense, as it does not lose its power by diffusing the rays constantly over the whole horizon, but gathers them up into a number of separate bundles or beams of great intensity. The apparatus of a revolving light has consequently more optical work to do than that of a fixed, for the rays must be bent not only in the vertical plane but laterally in the horizontal and in all intermediate planes as well.

In the construction of lighthouse apparatus either metallic or glass agents may be employed, but it has been found by experiments that a great saving of light (about 25 per cent.) is effected when glass only is used. All kinds of apparatus may conveniently be ranged either under the *catoptric system*, where metallic reflexion only is used, the *dioptric* where the material employed is wholly glass producing refraction and total reflexion, or the *catadioptric*, in which both glass and metal are employed.

CATOPTRIC SYSTEM of Illuminating every Azimuth with Light of equal Power either Constantly or Periodically

Passing over the early and rude expedients of such night marks Catoptric as open coal fires or naked candles placed in glazed lanterns, we system shall confine our attention to the gradual development of those optical designs

which are now or were lately adopted for lighthouse apparatus.

Parabolic Reflectors — In 1763, or at latest before 1777, parabolic reflectors were first used for lighthouse illumination by Mr

Hutchinson, dockmaster of Liverpool. In his work on *Practical Seamanship*, published in 1777, he states that the Merser lights were fitted with reflectors (figs 5 and 6) formed of small facets of silvered

FIG. 4.—Courses of various Lighthouse Towers.

Fig 5

Fig 6.

Parabolic reflectors

glass, and made, as Descartes nearly as they can be to the parabolic curve." This is unquestionably the earliest published notice of the use of parabolic reflectors for lighthouse illumination. Up to 1782 the wicks of the lamps were of a flat form, but in that year Augustin Imhof made wicks and burners of a hollow cylindrical form which admitted a central current of air through the burner, so as to ignite the cone of gas issuing from the wick both within and without. Rumford afterwards split up the cone of gas into several concentric shells.

"It is remarkable," says Mr J. T. Chance in his excellent memoir (*Atlas des Grands Eclairages*, vol. xvi.), "how many inventors have contemplated this respective parts to the multiple burner. — Augustin, the double current, Lange, the impenetrable contraction of the glass chimney; Carrel, the mechanism for an abundant supply of oil, and Count Rumford, the multiple burner, an idea made feasible by these contrivances, and finally realized by Augustin Fresnel."

Optical Properties of the Parabolic Reflector.—In the parabolic reflector all rays diverging strictly from the focus and falling on the paraboloid emerge in one beam of parallel rays. But as an oil light is not a mathematical point, but an object of considerable magnitude, the rays from the outside of the flame being evocal will, after reflection, emerge as a cone whose divergence is directly proportional to the radius of the flange and inversely to the focal distance of the reflector. Its intensity must consequently vary as the squares of the distances from the lighthouse. Optical sympathies does not then prevent that divergence which is due to the flame being of sensible magnitude.

Defects of the Paraboloid.—It will be seen from fig. 7 that the paraboloid mirror is at best but a very imperfect instrument, for even if the reflector was strictly a mathematical point, the cone of rays (shown undotted) escaping past the lips of the mirror must be lost.

FIG. 7—Vertical Section

FIG. 8—Plan

Mode of Employing Reflectors for Fixed and Revolving Lights.—In order to produce, on the optotype system, a fixed light showing all round the circle, a number of reflectors (a, a, a , fig. 8) are fixed round the outside of a stationary chandelier c . As the ordinary paraboloid has about $1\frac{1}{2}^\circ$ of divergence, twenty-five reflectors were needed to light up continuously (though not equally) the whole horizon. If again the light was to revolve, then a revolving chandelier (figs 9 and 10) was employed having a certain number of flat faces, on each of which was fixed a number of separate lamps and reflectors with their axes parallel to each other. When the chandelier revolved, and one of the flat sides was turned towards the sailor, he would, when at some distance from the shore, receive a flash at once from each of the mirrors which were on that face, but when the face was turned away from him a dark period would intervene until the next face came round again.

Bartholomew's Fixed Sideral, 1810.—In order strictly to equalize a fixed light over the whole horizon, which could not possibly be done with separate reflectors, Malet proposed this ingenious instrument, which is governed by the revolution of the parabolic profile pp' (fig. 11) round its parameter as a vertical axis, instead of round a horizontal axis, as in all former reflectors. The vertices of the parabola are cut off, so as to permit of a common focus for the flame.

The rays will therefore be reflected parallel to the horizontal axis in the vertical plane, while the natural divergence of the light in azimuth will not be interfered with. By this excellent contrivance the light was for the first time spread equally round the horizon in one continuous zone. But even though the reflectors were reduced to a mathematical point, very

many of the rays (shown in hard lines in the elevation, fig. 11) are allowed to escape past the lips of the reflector, and thus less takes place all round the circle.

FIG. 11

DIOPTRIC SYSTEM

Beginning in 1822, Augustin Fresnel, the eminent physicist and Dioptric mathematician, entirely revolutionized the previously existing light-system house system by means of his annular lenses, cylindrical reflectors, and totally reflecting prisms. Before describing these and their combinations it is necessary to state that the size of the flame produces divergence with lenses as well as with reflectors. The measure of this divergence for any point of the lens is the angle whose sine is

$$\frac{\text{Radius of flame}}{\text{Distance of point from centre of flame}}$$

Fresnel's Optical Aspects

Annular Lens, 1748-1822.—Buffon in 1748 suggested a new form of Fresnel's lens for burning purposes in order to save the loss of heat by annular absorption of the sun's rays in passing through a thick lens of large lens size whose outer periphery is continuously spheroidal. He proposed to grind out of a solid piece of glass a lens in steps or concentric rings in order to reduce the thickness to a minimum (figs 12 and 13). Condacnet, in his *Eloge de Buffon*, in 1778 (Paris edition, 1804, p. 85) proposed the capital improvement of building up Buffon's stepped lens in separate rings, and pointed out that the cutting of the surface into steps had the effect of converting to a large extent the spherical aberration, or divergence from the parallel, of the rays emitted by any continuously spheroidal lens. Sir D. Brewster, in 1811, also described the same plan. But both these writers suggested thin lenses for burning purposes only, and not for operating on light, while all the surfaces of their lenses were spheroidal. In 1822 Fresnel constructed a built-up lens for lighthouse purposes, in which the centres of curvature of the different rings receded from the axis according to their distance from the centre, so as practically to eliminate spherical aberration, the only spherical surface left being the small central part a (fig. 13). These lenses are used for revolving lights only.

Cylindrical Refractor.—This instrument was introduced by Fresnel Cylindrical for effecting dioptrically by refraction in front of the flame what reflectors

had been done before optically by Malet's reflector by reflection from behind the flame. It consisted of a zone or hoop of glass (figs 14 and 15) generated by the revolution round a vertical axis of the middle section of the annular lens just described, which lens, on the other hand, being generated by the same profile round a horizontal axis parallelled the rays in every plane, whereas the cylindric refractor does so in the vertical plane only.

Totally Reflecting Prisms.—Fresnel next conceived the admirable improvement of employing the principle of "total" or internal reflection by glass prisms. The rays Pa (fig. 16) falling on a prismatical ring, ABC , is refracted and bent in the direction aB , and falling on the side AG , at an angle of incidence greater than the critical, is totally reflected in the direction Ra , and, impinging on the side BC at c , it undergoes a second refraction, and emerges horizontally. The highest ray Pa after refraction by AB and reflection by AG must (in order to avoid superfluous glass) pass

FIG. 12—Elevation

FIG. 13—Plan

FIG. 14—Elevation

FIG. 15—Plan

FIG. 16—Vertical Section

FIG. 17—Plan

along AB, and after a second refraction at B emerge horizontally. The lowest ray EB after refraction by AB must, for like reason, pass along BC, and after reflection by AC and a second refraction by BC either ray incident on the prisms between A and B, after one reflection and two refractions, emitted horizontally.

Straight Refracting Prism—

Fresnel's straight refracting prism which refracts the rays that fall on it, but in one place only, requires no further explanation, as it is simply a straight prism of the same horizontal cross section as one of the prisms of his cylindrical refractor, so as when placed in front of his fixed apparatus to produce a beam of parallel rays like a lens.

Great Circular Lamp—We will now go on to describe the manner in which Fresnel united the four new optical agents which he originated, by first referring to his central burner system. In all lighthouses prior to 1822 the mode of getting up the required power was by employing a sufficient number of separate reflectors, each of which (unless we except Bonaparte's reflector) required its own separate lamp. Instead of numerous independent lamps and reflectors, Fresnel used a single lamp which had four concentric wicks, and was fed with oil by a pump worked by clock work. Surrounding this lamp was a stationary cylindrical reflector for a fixed light, and annular lenses revolving outside of it for a revolving light.

Fresnel's Combination of his Optical Agents

Catadioptric Fixed Light—This apparatus (figs 17 and 18), in which a central burner is used, consists of a dioptric cylindrical refractor with zones of silvered mirrors above and below similar in profile to Bonaparte's reflector. By the adoption of the

Fig. 17—Section

Fig. 18—Plan

reflector the whole of the wasteful divergence which occurs in Bonaparte's reflector is prevented. We have here a geometrically perfect combination, but it is not so physically, because metallic reflection is used. This physical defect Fresnel obviated in his next design.

Dioptric Fixed Light—First Application of Total Reflection to Fixed Lights—In this apparatus Fresnel substituted his totally

Fig. 19—Elevation

Fig. 20—Vertical Section

reflecting prism *p* and lens *r* for Bonaparte's reflector, and thus distributed the whole light equally over the horizon by means of dioptric agents alone. This was the first application of total

reflection to lighthouse apparatus, and this beautiful instrument continues to tell now in universal use. Figs 19 and 20 represent an elevation and section of this apparatus.

Fresnel's Revolving Light—In this form of revolving light (fig. Revoly 21) the central burner is surrounded by annular lenses *L*, and ing light,

Fig. 21—Vertical Section

on account of the employment of metallic reflection, and because two agents are employed for all except the central portion of the rays. *Fixed Light varied by Flashes*—This distinction (figs 22 and 23) Fresnel produced by placing his straight refracting prisms *p* on a revolving frame outside of his fixed light apparatus, so that when the upright prisms come in line with the observer the light is increased to the power of the revolving light, a broad flash *as* in the annular lens being placed in place of a narrow strip of rays as in the unsilvered fixed light.

Fig. 22—Plan

Fig. 23—Vertical Section

Alan Stevenson's Improvements

Mr Stevenson was the first to introduce the dioptric system into Alan Butan, and in doing so he made the following improvements. *Stevenson's Refractor of a Truly Cylindrical Form*—Owing to difficulties soon's in construction, Fresnel adopted a polygonal instead of a cylindrical preform for his refractor, but Mr Stevenson succeeded in getting Messrs. Messrs. Cookson of Newcastle to construct a flat order refractor of a truly cylindrical form.

2. Helical Glass Joints for Fixed Lights—Mr Stevenson further improved the apparatus by constructing the refractor in a rhomboidal method of rectangular pieces (figs 24 and 25), thus producing helical joints and preventing serious obscuration of the light in any azimuth.

3. Helical Metallic Framework—The internal metallic frame work for supporting the upper cupola of prisms was also, for the same reason, made by him of a helical form.

4. Diagonal Framed Lantern—The astragals or sash bars of the lantern were likewise made diagonal and constructed of brass instead of iron in order to reduce their sectional area. A small harbor light with inclined astragals was made in 1836 by Mr E. Sang. Mr Stevenson also prepared a design in 1846 for Start Point, Orkney, in which he extended the helical arrangement to the astragals, but it was never carried out. Mr Douglas independently designed and afterwards carried into practice this form of lantern.

Alan Stevenson's Improved Revolving Light for Skerryvore—In 1835 Mr Stevenson, in a report to the Northern Lighthouse Board, proposed to add fixed reflecting prisms *p* (fig. 26) below the lenses of Fresnel's revolving light, and he communicated this proposal to M. L. Fresnel, who approved of his suggestion, and

Fig. 24—Elevation

Fig. 25—Vertical Section

assisted in carrying out the design in 1849. This combination added, however, but little to the power of the flash, and produced both a periodically flashing and constantly fixed light, but it must be remembered that the prism for fixed lights was the only kind of reflecting prism then known. The combination of trapezoidal lenses and mirrors was also, for the same reason, still used. The prisms for Stearns were the first that were made of the large size (first order), and were constructed by M. Solin at Paris under the superintendence of Leonor Fresnel, the successor of his brother Augustin, then deceased.

Besides the designs which have been described for improving Fresnel's revolving light, there were many others, among which may be mentioned those of Leonor Fresnel, Sir David Brewster, W. H. Barlow, F. R. S., A. Gordon, Lepaute, Lescoum, Reynaud, and Taboret, but in all these, as well as in those which have been described, the rays were either not parallelized in every plane or else unnecessary agents were resorted to for that purpose.

T. Stearns's Holohedral System

It was not till 1849-50 that the problem was first solved of condensing the whole sphere of rays diverging from a flame into a single beam of parallel rays without any unnecessary reflections or refractions.

Catadioptric Holohedra.—In Figs 27 and 28 part of the anterior hemisphere of rays is intercepted and at once parallelized by the

Fig. 27—Vertical Section

Fig. 28—Front Elevation.

lens L, whose principal focus (f , for parallel rays) is in the centre of the flame, while the remainder is intercepted and made parallel by the paraboloid a , and thus the double agents in Fresnel's design are dispensed with. The rays of the posterior hemisphere are reflected by the spherical mirror d back again through the focus, whence passing onwards one portion of them falls on the lens and the rest on the paraboloid, so as finally to emerge in union with and parallel to the front rays. This was the first instrument which intercepted and parallelized all the rays proceeding from a focal point by the minimum number of agents. It is therefore geometrically perfect, and was called by Mr. Stearns a holohedra, but it is not physically so, for it employs installa reflexion, and with an ordinary oil flame and burner some of the rays reflected by the spherical mirror would fall upon the burner and be lost. This instrument was first employed at the North Harbour of Portland in 1849.

Holohedral Catadioptric Apparatus Revolving round a Central Flame.—If in place of Fresnel's compound arrangement of trapezoidal lenses and plane mirrors there are substituted mirrors B, B' (fig. 29) generated by the revolution of a parabolic profile round a horizontal axis, all the light will be at once sent out in parallel beams by them and the lenses L, and the apparatus is therefore geometrically perfect, but metallic instead of glass agents are still employed.

Fig. 29.—Vertical Section

T. Stearns's Holohedral Dioptric Agents

The agents for revolving the holohedra purely dioptric fall next to be described.

Holohedral Prisms, 1850.—If prisms are generated by the revolution of sections of Fresnel's prisms round a horizontal instead of a vertical axis, as shown in fig. 30, rays incident upon them will be made parallel in every plane instead of in the vertical plane only as in Fresnel's prisms.

In 1850 it was stated that A. Fresnel, in 1828, tried prisms of this kind on lamp-posts for the quays of a canal in Paris, but their use was discontinued. They were not so arranged as to be applicable to lighthouses, and no account of them was published.

Double Reflecting Prisms giving Two Internal Reflections instead of One, 1850.—The object of these prisms is to reflect the rays back through the focus. The rays from f (fig. 31) pass normally through

Fig. 31—Vertical Section

the surface bc and fall upon the surfaces ab , ac , by which they are totally reflected and sent back to the flame.

Optical Combinations of Dioptric Holohedral Agents

Dioptric Holohedra with Dioptric Spherical Mirror.—If rings of Dioptric holohedral prisms p , p (fig. 32), combined with a central refracting holohedral lens L, subtending together 180° , be placed before a flame, the whole width of the front half of the diverging sphere of rays will be at once mirror condensed by refraction and total reflexion into one beam of parallel rays. Next, if there be placed behind the flame a dome of glass a formed of zones generated by the revolution of the cross-section of the double reflecting prisms round a horizontal axis, the back hemisphere of rays will, after the double reflexion, be returned by it through the flame so as to diverge along with the front rays; for this dome is a perfect mirror, not only for the faint light that is superfluously reflected by the first concave surface, but also for the main portion of the rays which enter the substance of the glass and are three totally reflected. Thus the whole light is parallelized entirely by glass agents. This combination should therefore produce the light of maximum intensity, being both geometrically and physically perfect when the radius is a luminous point. Still, some of the rays reflected by the upper and lower parts of the mirror will not clear the burner of an oil light, but falling on it will be lost.

Fig. 32—Vertical Section

Dioptric Holohedral Revolving Light.—Application of Total Revolving Reflexion to Revolving Lighthouses, 1850.—If sections of the front half of light

the dioptric holohedra be arranged as a polygonal cage round a large central flame and made to circulate round that flame, a revolving light with its periodic flashes will be produced (fig. 33), which is characteristically geometrically and physically perfect, and the double agents used in Fresnel's revolving light are thus wholly dispensed with. Mr. J. T. Chance says, "on the whole the modern plan (holohedral) must give light five or six times more intense than that of the former (Fresnel's) arrangement." The greater simplicity and compactness of this light may be seen in comparing figs. 21 or 23 with fig. 33.

The holohedral revolving light is now the only one that is employed for all new lights. It was first introduced in 1850 on the small scale by Messrs. Stevenson at Harburgh Rock, Singapore, and on the larger scale at North Ronaldshay in Orkney, the prisms of which were most successfully made in 1851 by Letourneau of Paris.

Fig. 33—Elevation

Fixed
light
with
dishes

Holophotal Fixed Light erected by Flinders—Flinders' double agents (figs. 21, 22) are here also dispensed with by the single agency of panels of fixed light apparatus p', p' (fig. 34) and cylindrical reflectors L, L , alternating with panels of holophotal apparatus p, p, L, L , both of which revolve together round the central burner.

Back
pans

Back Pans—It will be noticed that, while perfection was attained by single agency in Flinders' fixed apparatus and also in the holophotal revolving apparatus, a physical defect still attached to every form of holophotal which compressed the light into a single beam where the rays require to be sent back through the flame. The defect is not a geometrical one, and would be non-existent were the luminant a mathematical point. In order to remedy this objection, Mr. T. Stevenson and Mr. Diebler designed what they termed "back" pans, capable of directing the rays through an angle of 180° , so that the engine becomes virtually independent of the optical angle.

Professor Swan of St. Andrews also independently proposed the same kind of pans, accompanied by general formulae for its construction. The ray ab (fig. 35) is refracted at b , totally re-

FIG. 34.—Vertical Section

FIG. 35.

fracted at c , and again refracted at d , so as to pass out parallel to the horizontal axis. These pans may be formed by the revolution of the generating section round either a vertical or horizontal axis, or they may be made straight as shown in elevation and section in the diagram.

The "back pans" which were first used in Islay, Argyllshire, were made by Messrs. Chance in accordance with Professor Swan's formula.

Perfect
form of
holo-
photo

Perfect Form of Dioptric Holophote for an Oil Flame—By combining the back pans p, p , (fig. 36) just described with a semi-holophote abc subtending 180° and a portion of the dioptric spherical mirror, no light is lost on the burner, and all the rays are parallelized, so that this apparatus, being all of glass, is both geometrically and physically perfect.

Chance's
improvement

J. T. Chance's Improvement of 1862—Mr. Chance says, "The plan of generating zones round the vertical axis (instead of the horizontal) was introduced by the author, who adopted it in the first

FIG. 36.—Vertical Section

FIG. 37

complete catoptrical mirror which was made and was shown in the exhibition of 1862 by the Commissioners of Northern Lighthouses,

for whom it was constructed, in order to further the re-erecting of what Mr. T. Stevenson had ingeniously suggested about twelve years previously. During the progress of this instrument the idea occurred to the author of separating the zones (fig. 37) and also dividing them into segments like the ordinary reflecting zones of a dioptric light, by this means it became practicable to increase considerably the radius of the mirror and thereby to render it applicable to the largest sea light without overlapping the limits of the angular breadths of the zones, and yet without being compelled to resort to glass of high refractive power."

Mr. Stevenson states (*Mar. Eng.*, vol. xxvi.) that he originally intended to generate the pans round a vertical axis, but adopted the horizontal as more practicable where fine glass which was taken out of the melting pot on the end of a rod had to be employed for the most important and smaller central parts of the apparatus, which at that date were the only ones that could be constructed.

Professor Swan's Designs—Among several ingenious arrangements and new forms of agents proposed by Professor Swan¹ is design

the mode of sending rays from pans through inter-shoes left between other pans placed in front, and also a form of agent which he termed the thesoptric pans, in which the rays would undergo two reflections and three refractions. In fig. 38 a are the front and b the thesoptric pans. The two upper and lower pans a are constructed of flat glass of high refractive power. It will be observed from the drawing that this ingenious arrangement is nevertheless open to objection, for cones of light of 80° in front and of 60° at the back are lost through the substrations.

FIG. 38.—Vertical Section

T. Stevenson's Aximuthal CONDENSING SYSTEM for Distributing the Light Unequally in Different Directions either Continuously or Periodically

PICURUS to 1850 all apparatus was designed to emit light of Condens equal power in every azimuth either constantly or periodically, so that when applied to illuminate sea extending farther in some system directions than in others, such, for example, as long narrow sounds, the power was either needlessly great in some azimuths or not nearly strong enough in others. The only exception was where a tower was placed on a long straight coast, when a spherical mirror was fixed behind the flame to prevent the light passing landward. The light that would have been lost on the land was, in this way, sent seawards, but no attempt was ever made to condense the light over a given arc or to allocate this auxiliary light in proportion to the varying lengths of the different ranges and the amplitudes of the arcs over which it had to be sent, nor where a light had to show all round the horizon, to weaken its intensity in one arc and with the rays so abstracted to strengthen some other arc which from its range being longer ought to be of greater power. As the optical agents which we have described were insufficient for this purpose, it became necessary to devise new agents possessing special optical properties, for distributing the rays not equally but equitably. Some of the more important of these agents and their combinations will be described, but before doing so it is necessary to make some preliminary explanations.

The form of the emergent light from condensing apparatus is neither a solid beam of parallel rays like that from an annular lens nor yet a zone of rays diverging naturally in azimuth all round like that from an ordinary fixed apparatus, but is intermediate between these, being a solid angle or wedge of light strengthened by these rays which would naturally diverge in other directions, but which are diverted and spread over the given sector as shown perspectively in plan in fig. 39, in which L represents the position of the lighthouse, LD'

FIG. 39

¹ "Professor Swan's Designs," *Trans. Roy. Soc. of Arts*, 1867-68.

the range, or distance it sea from which the light can be seen, and **DEVELOP** the solid horizontal angle that is to be illuminated and into which all the light DAD' which would naturally diverge over the rest of the circle must be compressed, and over which it must be uniformly spread.

Fixed condensing prisms

Requirements for Fixed Condensing Lights—1. Where a light has to be seen constantly over only one arc of the horizon, the apparatus must compress all the rays within that one arc whatever its amplitude may be, and spread them uniformly over it.

2. Where the whole horizon has to be constantly illuminated, but the light has to be seen at greater distances over some parts of the sea than over others, so much light must be abstracted as can be spared from the shorter ranges and directed to the longer so as to allocate the rays in the compound ratio of the number of degrees and the squares of the distances from which the light has to be seen in each arc, and the light thus diverted from one arc to strengthen another must be spread uniformly over the one that has to be strengthened. By this mode of abstraction and addition there is produced a constant equitable distribution over the whole horizon of all the rays from any single flame. Where the whole horizon has to be lighted, and where more than one arc has to be strengthened, the rays which would be lost on the land or can be spared in some other direction must be directed to and spread uniformly over these arcs in proportion to their amplitudes and ranges.

Revolving condensing lights

Requirements for Revolving Condensing Lights—1. Where a light has to give its flashes periodically over only one arc of the horizon, all the rays must be collected and sent out periodically in solid beams of equal power over that arc.

2. Where the whole horizon has to be periodically illuminated, but where its flashes have to be seen at greater distances over some parts of the sea than over others, the apparatus must be made (as in number 2 of the fixed condensing light) to vary proportionally the power of the flashes whenever they begin to pass over those parts of the sea where the ranges are of different lengths so as to produce an equitable periodic distribution of all the rays.

3. Where the whole horizon has not to be lighted, and where more than one arc has to be strengthened, the rays which would be lost on the land or can be spared in some other direction must be directed to and spread uniformly over these arcs so as to strengthen the flashes in proportion to their amplitudes and ranges.

If a be the number of degrees in an arc to be illuminated, and d the distance in miles to be traversed by the light, then, neglecting atmospheric absorption, the quantity of light to be allocated to that arc will be proportional to ad^2 , but if we take account of atmospheric absorption, supposing g to be the quantity out of a unit of transmitted light which escapes absorption after passing through a mile of air, then the whole light needed by the arc to be illuminated will be proportional to $a \cdot ad^2 \cdot g^d$. Supposing now that L is the whole 360° of available light from the apparatus, the quantity to be apportioned to the given arc will be $mL/2\pi a$, where $2\pi a$ denotes the sum of the several numbers m computed for the respective arcs of the horizon.

The Principal Optical Condensing Agents

Condensing straight prisms

Condensing Straight Prisms—These, either by reflection or refraction at both, cause a ray fr (fig. 40) proceeding in any compass

Fig. 40

bearing from a fixed light apparatus AA to emerge in the direction, eg , parallel to the corresponding ray fb , which proceeds in the same compass bearing from another part of the apparatus and so of any other ray fr which is sent parallel to the ray fb .

Right-angled prisms

Right-Angled Expanding Prisms—These (fig. 41) are right-angled vertically, while ac plane two of them C_1O_1 are semi-cylinders, and the third C_2 a semi-cone. A semi-cylindrical beam of parallel rays passing vertically upwards and falling normally on the bases a of the prisms enter the glass, are reflected

Fig. 41

by the sides b , and pass out horizontally and normally to the other sides, but, as the prisms are bent through a circular segment dad' in plane, the emergent rays will be spread over the same angle in azimuth, and this will be true of any angle in azimuth subtended by the prisms. As those in the diagram subtend 180°, the light will in this case be spread over half the horizon dad' .

Turn Prisms—These are for carrying out Professor Swan's mode of causing light coming from prisms behind to pass through spaces left for the purpose between others in front. The turn prisms (fig. 42) are formed by cutting out the apex (shown black on diagram) of a straight prism so as to leave a sufficient space between it and the next prism for the passage of rays coming from behind. The length of glass traversed by the rays is lessened by this arrangement, and the size of the apparatus and lantern can at the same time be very greatly reduced.

Fig. 42

Diffracted Lens—Horizontal divergence may be obtained by any Difference amount by varying the radius of curvature of the inner tall lens and refractor.

Fig. 43

Fig. 44

Fig. 45

Diffracted Refractor—This is the application to the cylindrical refractor of the same principle which has been described above to the ordinary annular lens.

Condensing Catoptric Spherical Mirror—If a large arc of a Spherical mirror be cut opposite to a short range of sea, and a mirror smaller arc be cut in the mirror opposite to the longer range which has to be strengthened, then the light passing through the larger arc is received on an elliptic reflector placed behind, so as, with the help of an additional reflector and lens, to cause the larger cone of rays to be compressed into the smaller arc which has to be strengthened.

Spherical Mirror of Unusual Size—This mirror is set out in height in such a way that its different heights represent inversely the different distances of the neighbouring land from the light-house, so as to reflect less light in the shorter and more in the longer ranges.

Application to Fixed Condensing Apparatus

Fixed Condensing Light for a Single Sector, 135°—The heliophote light in plp (fig. 46) throws its whole light on straight condensing prisms ac , each of which distributes the rays over the required sector.

Condensing Apparatus for Steamers' Side Lights—By means of this apparatus of the condensing prisms (figs. 47 and 48) all the light can be distributed with strict equality over 115° 30', which is the arc prescribed for steamers by the Board of Trade. Several of the Transatlantic and other steamers have adopted the kind of apparatus, which is hung on gunbells and placed in iron towers, having an entry from below the deck, which can be made use of in bad weather.

Condensing Quadrant—The fixed apparatus 304 , with spherical condenser behind, throws its rays directly through the angle of 90° quadrant afg , while the supplementary rays falling on the straight condensing prisms p, p', p' (fig. 49) are sent out parallel to the corresponding rays in the unobstructed central quadrant of the main apparatus. The whole light will therefore be condensed equally over 90°.

Fig. 46—Vertical Section.

Condensing Optical—The central fixed apparatus 46 (figs. 50, 51) with spherical mirror *ad* throws its rays directly over the angle of 45° *ppq*, while the supplemental rays fall upon the straight condensing

FIG. 47.—Side Elevation

ing prisms *p*, each of which spreads the incident rays parallel to the corresponding rays in the central angle *ppq*. In this way the whole of the front hemisphere of rays is parallelized in the vertical

FIG. 48.—Horizontal Section

plane and spread equally over the 45° in azimuth. The hemisphere of back rays is condensed into the same arc seawards by the dioptric spherical mirror, which returns the rays incident upon it through

FIG. 49.—Horizontal Section

the flame, where mingling with the front rays they are finally distributed over the arc of 45°. The light passing above the spherical mirror is parallelized by a half holophote *ab* (fig. 50), and sent

FIG. 50.—Vertical Elevation

vertically upwards, when, falling on the expanding prisms *of*, it also is finally spread over the isosceles arc. Thus the whole light is condensed and distributed with strict equality over the 45° by means of six different optical agents. Two apparatus of this kind form the leading lights to the River Tay.

Condensing Optical—Fig. 52 shows part of the Lamplish light in the Firth of Clyde. Its action will be easily understood by the numbers shown on the diagram.

Fixed Condensing Lights for more than one Sector of Unequal Range.—Fig. 53 is a chart of the Sound of Glenelg, in which the Isle Oranay light has to be seen generally at a distance of 3 or 4 miles across the Sound, but in the direction

FIG. 51.—Horizontal Section

Condensing twin prisms

Light for sectors of unequal range

FIG. 52.—Horizontal Section

another up the sound between C and D an angle of 10° has to be seen about 7 miles. Fig. 54 shows in plan the apparatus, which was for certain local seasons not constructed according to the

FIG. 53

formula, but 168° of the spare light which would otherwise have fallen upon the land were allocated down Sleat Sound and 139° down the Sound of Glenelg. That for Sleat Sound was given

FIG. 54.—Horizontal Section

FIG. 55.—Vertical Section

directly by the main apparatus through the arc *h*, and that to Glenelg through the arc *g*, but these arcs were respectively strengthened by portions of the holophotes B and C, the light from which was condensed respectively over the arc *h* by each of the straight prisms *a* and over the arc *g* by each of the prisms *b*. The condensed light at Isle Oranay, which is of the fourth order, appears to be equal to that of a first order, so that with a

lamp consuming annually only 170 gallons of oil a light is obtained in the only direction in which great power is required equal in effect to a lamp consuming 800 gallons per annum.

Fixed Condensing Lights of Unequal Range which constantly illuminate the whole horizon.—For this purpose the condensing apparatus of mirror or spherical mirror of unequal area will be found applicable.

Revolving or Intermittent Lights for Condensing the Rays into one Sector.—The heliophote in fig. 55 shows its rays on straight condensing prisms P, each of which spreads the light over the required sector, while making M to revolve horizontally on pivots cut off the light either slowly or suddenly so as to produce a revolving or an intermittent light, both of which condense all the rays uniformly over the one sector.

Application of Condensing Prisms to Revolving Lights of Unequal Range, which do not illuminate the whole horizon.

Repeating Light.—Plane mirrors M (fig. 56) revolve on an endless screw placed outside of the apparatus and alter the direction of the flashes after they pass into the dark arc on the landward side so as to cause the lenses L, L to repeat their flashes over the seaward arc which requires strengthening. The condensing spherical mirror and mirror of unequal area will also be found applicable in cases where the flashes do not require to sweep over the whole horizon.

FIG. 56.—Horizontal Section

Condensing Intermittent Lights.—Figs. 57 and 58 show straight refracting or reflecting prisms, which revolve and intercept as they pass round certain of the rays from a central fixed light apparatus so as to produce perfect darkness over the sectors which they subvert at the time, while they spread the rays which they intercept uniformly over and thus strengthen the intermediate sectors which are illuminated directly by the central apparatus.

FIG. 57.—Horizontal Section

FIG. 58.—Elevation

The peculiar property of this arrangement is that the power is increased in proportion to the duration of the intervening periods of darkness. Thus, neglecting the loss by absorption, &c., the power is doubled when the periods of light and darkness are equal, tripled when the dark periods are twice as long as the light, and so on in proportion, while in every case the rays are spread uniformly over each illuminated sector.

Revolving Condensing Light with Differential Reflector.—Figs. 59 and 60 show the new apparatus of Mill of Galloway in which the differential reflector, by the compound horizontal and vertical section of which angle agent the whole condensing intermittent effect is produced, so that condensing prisms are done

away with opposite the central, which is the most important, part of the apparatus. The centre of the inner curve of the refractor is at O in fig. 60. Through there is no relative motion in this apparatus, every part of which revolves together, the parts may be arranged so that the condensing only move. This apparatus was constructed in the most satisfactory manner by Messrs. Baillet & Penet, Paris.

Alteration of Fixed to Intermittent Apparatus.—Any existing fixed light can at once be made intermittent so as to show either equal or unequal periods, by simply causing condensing prisms to circulate round it, while the power will be increased in proportion to the ratio of the duration of light to dark periods.

FIG. 60

Change of fixed to intermittent apparatus

Beacons and Buoys

Beacons in exposed situations are constructed sometimes of Beacon stones, and cement concrete or cement-rubble, but generally of cast-iron columns let into heavy base plates which are fixed to the rock by strong Lewis bolts. The small class iron beacons are generally of malleable iron and the larger of cast-iron, but steel or bronze might with advantage be used in very exposed places. Fig. 61 shows a first order cast-iron beacon as used in Scotland.

T. Stevenson's Apparent Light.—This kind of light is specially useful at places where there is a sunk rock with little sea-room round it, and at the piersheads of harbours which must be closely hugged by vessels seeking entrance. It consists of certain forms of optical apparatus for reflecting and redistributing at a beacon placed on a submerged rock parallel rays which proceed from a lamp and apparatus placed on the land. An optical deception is thus produced, as the sailor initially supposes that there is a lamp burning on the beacon itself. The first light of this kind, which has been in use since 1861, was placed in a beacon on a sunk reef in Sornoway Bay, and is shown pictorially in fig. 62. This light is 530 feet distant from the lighthouses where the lamp is placed. Others have since been established at Grampouth, which is 235 feet from the light, and at lesser distances at the harbours of Ayr and Abroath, at Odessa in the Black Sea, and at Gatcombe Head, Queensland.

FIG. 61

Beacon Lights.—Lamps without glass chimneys, as used in the Beacon early experiments with paraffin, and as used with gas in Parker's lights buoy, having iron tubes placed at certain distances above the flames, and supplied with very large external of crystal oil, have been kept continuously burning in Scotland for about a month without turning. These lamps are for rocks at sea which can only be reached when the weather is moderate.

Illumination of Beacons by Gas to Produce a Fixed Light.—A light near Port-Glasgow has been illuminated by gas since 1861. The tower is about 300 feet from the shore, and the supply and pressure of gas are regulated by self-acting arrangements on the shore.

Pat. 15. *Proctor's Gas Illuminated Buoy for Producing a Fixed Light*—This buoy is gas and water tight, and is charged to a pressure

around the whistle. It is said that an undulation of even 12 inches is sufficient to sound the whistle.

Fig. 62

of ten atmospheres. The buoy is filled with gas sufficient to burn night and day for three or four months, the burning pressure is kept constant by Proctor's regulator. These buoys promise to be of great service, and have now been in use for more than a year at several places both in England and Scotland.

Automatic Meter for Producing Intermittent Lights by the Flow of the Tide—In order to distinguish one buoy or beacon from another, Mr. T. Stevenson has proposed to make the flow of the gas itself produce automatic intermittent action without using clockwork. The full flame continues to burn until the action of the meter reduces the supply, but leaves a small jet still burning in the sockets of the burner till the full flame is again produced. This meter has been tried successfully on shore for twenty-eight hours consecutively.

Uniform System of Beacons and Buoys—The first proposal for a system of dealing systematically with the colours of beacons and buoys was in 1828, when Mr. R. Stevenson proposed for the navigation of the

Fig. 63—Combs's Automatic Buoy. A, cylinder, 27 ft. 6 in. long; B, moving shaft; C, boiler; D, buoy; E, diaphragm; F, ball valves; G, an inlet tube; H, an (compressed) outlet tube to whistle; I, compressed inlet to buoy; K, manhole; L, steps; N, whistle.

river Forth that red buoys should be taken on the starboard and black on the port side in going up the river. This system has since been adopted generally in the United Kingdom. In 1857 Admiral E. J. Belford suggested a uniform system for all the coasts of the country, which was carried out in Scotland by Mr. A. Cunningham. A different uniform system has been adopted in England by the Trinity House. In 1859 Mr. J. F. Campbell suggested what is undoubtedly the best system, that a buoy shall indicate by its shape and colour the compass direction in which a vessel should sail after seeing the buoy.

Combs's Automatic Buoy—This useful form of buoy (fig. 63) first used in America, has a cylindrical tube A projecting below the level of the water, on the upper part of which cylinder there is a whistle N and also two inlet valves F, F, so that the rising and falling of the buoy draws in and expels the air alternately which

Tolling of Bells by the Hydrostatic Telling of the Force of the Tide—In 1810 Mr. R. Stevenson designed apparatus for tolling with a bell on the Gun Rock lighthouse, which was to have been effected by a float when ascending with the pressure of the flowing tide, when descending with the fall of the ebb tide and by means of a peculiar arrangement of weights for keeping the bell in action during the time of slack water.

ILLUMINANTS

After a good ordinary single-wick oil lamp, Fresnel still adhering to Argand's principle of the double or current intro-

duced two, three, and four concentric wick burners, Mr. Alan Stevenson the five, and Mr. Douglas the six wick burners. These burners are suitable for the consumption of animal and vegetable oils, which

were in use at the various lighthouse services of the world till within the last few years. These oils are, however, superseded by hydrocarbons, which at one-half the cost give an increased luminous intensity for an equal consumption, but they require a larger supply of air for their combustion, and consequently an improved form of burner. Mr. Main in 1856 devised a single-wick burner for this purpose which gave good results, but many and all attempts to construct a multiple-wick mineral oil burner failed till 1868, when Captain Doty's famous device.

By a happy choice of proportions in the various parts of his burner (fig. 64), and by the addition of an exterior cylinder surrounding the outer wick, and a central disk, both placed in such a manner as to throw a current of air into the flame at the right place, Captain Doty succeeded in producing single and multiple-wick hydrocarbon burners, which carry a flame of great luminous intensity and regularity. The following table gives the details of these burners, and also the candle power and consumption, as determined by Dr. Stevenson Macadam.

Fig. 64

No. of Wicks	Main Diameter of Outer Wick, in inches	Height of wick part of Flame, exclusive of Trill, in inches	Candle Power in Spec. Oil, each consuming 120 grs. Spirit per Hour	Value of Light from Consumption of 1 gallon of Oil in 24 hours
1	0.2	1	28.62	27.29
2	1.75	1.5	63.75	27.29
3	2.5	2	90.72	27.29
4	3.2	2	107.62	27.29

Mr. J. K. Douglas has also introduced a mineral oil burner, which, however, Doty claims as similar in principle to his. By igniting only half the number of wicks (the outer in a six-wick for instance) the use of the burner can be diminished by one-half. This is Mr. Douglas's lamp of single and double power for use in clear and foggy weather respectively.

The mineral oil employed most extensively in light-houses (illumination is Scotch paraffin). The specific gravity, which is a test of the relative values of the oil, should be from 0.8 to 0.82 at 60° Fahr., and the flashing point at temperature at which it begins to evolve inflammable vapour should not be lower than 125° nor higher than 185° Fahr. The Board of Northern Lighthouses was the first light-house authority in Britain that adopted paraffin and Doty burners, and by doing so an annual saving of between £4500 and £5000 in the maintenance of the lights on the Scotch coast was effected.

Single-wick burners are supplied with oil from the cistern by the capillary action of the wick alone. But in the case of multiple-wick burners other methods must be employed to secure a sufficient supply. If the cistern be placed above the level of the top of the burner, the flow of the oil to the wick ends is effected by the direct

action of gravity, regulated by a contrivance which maintains a constant head. If, however, the lantern be placed below this level, either a mechanical pump is employed, in which the oil is forced into the burner by pumps worked by clockwork, or a moderator lamp, in which this is effected by the pressure created by a weighted piston descending in a cylinder forming the lantern.

Cocle-Gas—Coal-gas was first used as a lighthouse illuminant at Salvoe, near Trieste, in 1817. For many years it has been used in the harbour lights of Great Britain when in the neighbourhood of gas-works. Mr J R Wigham has designed a compound or cocle burner consisting of a group of twenty-eight vertical tubes, each carrying an ordinary double-bell-tower burner, and the ignited gases issuing from all these jets unite into one large flame. Additional groups of twenty jets each can readily be arranged around the first, which forms a central nucleus, and in this way, depending on the state of the atmosphere, the power of the burner can be made at will 25, 45, 65, 85, or 105 jets. Fig 65 shows the arrangement

Fig 65

Fig 66

Fig 67

for 25 jets, and fig 68 one for 105 jets. In his triaxial or quadriform systems Mr Wigham places two, three, or four of the burners already described vertically one above the other (fig 67), with lenses opposite to each. The following table gives the candle powers, &c., of Mr Wigham's burners.

Number of Jets	Consumption of Gasol litres per Hour	Candle Power in Spinal Candles, consuming 100 gas per Hour
25	14.4	420.6
45	23.2	523.0
65	34.9	716.0
85	54.0	1100.0
105	80.0	1512.0

The diameter of the 105-jet burner is 12 inches

Faraday and Holmes's Magneto-Electric Light—In 1858 Professor Holmes made the first magneto-electric machine for lighthouses, which was tried by the Trinity House in 1857, and the electric light was first shown to the mariner in 1855. The Trinity House subsequently introduced it at Dungeness in 1859, and at Souter Point in 1871. The optical apparatus for these lights was designed by Mr J T Chance. In 1869 Holmes constructed for the Trinity House a dynamo-electric machine (in which no permanent magnet is used), giving a light of about 5800 candles. The magneto electric light of Holmes is exhibited from a third order dioptric apparatus at the South Foreland light has been estimated at 150,000 candles, or twenty times that of the old first order dioptric flash white light. The following table shows the results which have been obtained by Dr Tyndall and Mr Douglass by the magneto-electric and dynamo-electric machines, tried at the South Foreland, 1876-77—

Name of Machines	Cost.	Light in candle power	Light produced per HP as stated in Candles	Max Mean	Order of Merit	
Holmes's Magneto-Electric	£50	22	400	476	6	
Albion	404	2	400	541	5	
Giuseppe Dynamo-Electric (No 1)	320	42	430	1,257	7	
Do do (No 2)	250	571	420	1,277	8	
Swanwick's	200	8	430	1,212	9	
Do do (small No 5)	100	100	32	550	1,022	2
Do do (small No 6)	100	2	550	1,080	1	
Two Holmes's Magneto-Electric	1,100	60	490	479	428	3
Two dynamo Electric	640	10	420	1,061	651	4
Two Swanwick's (small Nos 5 and 6)	200	60	550	2,141	1,201	1

It may be kept in view that in the electric as well as in every other light the following requirements must be fulfilled—(1) it shall be constantly in sight during those periods of time at which it is advertised to the mariner as being visible, (2) it shall be seen as far as possible in a thick and hazy atmosphere, (3) it shall constantly maintain on the distinctive character of the station where it is employed so as not to be mistaken for another light, and (4), when revolving, its flashes shall remain long enough in view to let the sailor take the compass bearing of the light. The electric light practically fulfils all these conditions, and, when we consider its transcendent intensity, and the smallness of the luminous incandescence which enables the engineer to adapt it to any required conditions far more strictly than oil light, we may certainly conclude that the electric is the best though the most costly of all illuminants.

The only question which has not yet been decided is whether an electric light of equal initial power will penetrate a hazy atmosphere as far as an oil light. Experiments made at Edinburgh in 1866 seemed to show that the highly distinctive flash of the electric light when acted on by optical apparatus is perhaps not so much due to a greater amount of light as to the more complete parallelism of the rays arising from the smallness of the radiant. The apparatus of a small size which was first used both in England and France recently produced a useful vertical divergence, and has therefore been now justly discarded.

Allard's Statistics of Lighthouse Apparatus.

The following useful formulae are taken from M Allard's very valuable *Mémoire sur l'Éclairage et la Puissance des Phares*, Paris, 1876 statistics *Conservation of Oil in Relation to Diameter of Burner*—If c denote the consumption of mineral oil in grammes per hour, d the diameter of the burner in centimetres, then

$$c = 4.9d^{2.25}$$

Luminous Intensity—A Cocle burner consuming 40 grammes of colza oil per hour being taken as unit, if I denote the intensity for mineral oil in a burner of diameter d in centimetres, then

$$I = 0.22d^2$$

Luminous Intensity of Apparatus—Loss due to Reflection, Absorption, and Flaring of Apparatus—The loss due to reflection on entering and leaving the glass may be valued at 650, 652, 658, 676, 720, 730, for angles of incidence respectively of 0°, 15°, 30°, 45°, 60°, 75°. In totally reflecting mirrors the luminous ray suffers three deviations instead of two, therefore the above values should be multiplied by 3.

The loss by absorption in the glass, although properly given by an exponential formula, may, with sufficient accuracy, be taken as 68 per centum of the glass traversed.

The loss due to the horizontal joints of the lenses, and to the intervals between the reflecting rings, varies from 62 to 68, or from 0.7 to 0.4, in passing from the first to the fifth order.

Coefficients—These are the ratios in which the intensity of the lamp is increased by the apparatus. Where m is the coefficient, f the focal distance, d the diameter, and h the height of flame in a fixed light apparatus, they can, if expressed in centimetres, be calculated from the formula—

$$m = \sqrt{\left(\frac{f}{d}\right)^2 + 1} \quad \text{or} \quad m = 2.12 \left(\frac{f}{h}\right)^{1.15}$$

Annular Lens—The intensity of an annular lens is obtained by multiplying that of the corresponding fixed light by $\frac{1}{2}$, where ϕ is the angle subtended by the annular lens, and h the horizontal semi divergence. The intensity of light from an ordinary fixed light apparatus is increased 28 per cent. by the use of the dioptric spherical mirror.

Distinctions of Lights

The most important characteristic distinctions of lights are the following—(1) The *fixed light*. Two of these are sometimes shown tiers at different heights from the same tower. (2) The *revolving light*, which at equal and comparatively long periods comes slowly and gradually into full power, and then as gradually disappears. (3) The *flashing light*, which at short periods (such as a few seconds) comes very quickly, though gradually, into full power, and as quickly and gradually fades away, was first introduced by the late Mr Robert Stevenson in 1825. (4) The *coloured light*, which is obtained by using coloured media, and was first employed by Hills of Bradingham. (5) The *intermittent light*, introduced by the late Mr R Stevenson in 1830, which bursts instantaneously into full power, and after remaining as a fixed light for a certain length of time is as suddenly eclipsed and succeeded by a dark period. When the periods are very short the intermittent is used.

¹ This result as to total resistance is not in accordance with the experiments of Professor Potter, which, however, were made with a very finely polished glass made for optical purposes.

called an occulting light. (3) *The intermittent light of unequal periods*, first proposed by Mr R. I. Stevenson in 1871, showing from the same apparatus different durations of the dark periods with equal periods of light, such as fixed for 2' eclipsed 5', fixed 2' eclipsed for 2', and then, as at first, fixed for 2'. (7) *Group flashing light*. This distinction consists in giving a series of groups of two or more flashes separated by short eclipses, the groups being separated from one another by a longer eclipse. The Mr Wigham of Dublin first proposed this distinction, and applied it to a dioptric revolving apparatus illuminated by gas, the effect being produced by raising and lowering the gas. Mr Wilson of Troon had done in 1847. Dr Hopkinson produced the same effect optically and for the luminous by the arrangement of the ordinary revolving apparatus. (8) *Fixed lights illuminating the whole horizon*, but showing revolving or intermittent characteristics over small areas. These can be produced by masks arranged like romanian house blinds placed opposite the arc where the characteristic is to be different from the main light. This arrangement and No. 9 were lately proposed by Mr T. Stevenson. (9) *Intermittent flashing light*. This is produced by condensing prisms revolving round a fixed light apparatus. The flashing light continues giving its rapidly recurring flashes for a certain period, which is succeeded by a dark period. The light which is not returned during the dark periods is condensed by the prisms so as to strengthen the light periods.

Uniform System of Characteristic.—Various modes of distinguishing lights have been at different times proposed, such as Babbage's, which represented the stations by numbers, and Sir V. Thomson's by the Morse alphabet, or dots and dashes, but the following results seem to show that the present system is satisfactory, while it is free from many objections to which the other modes are liable. The Board of Trade records of shipwrecks show that during the space of twenty years (1857 to 1876) 2716 vessels were wrecked by stranding on the coasts and shoals of Scotland and the Isle of Man, and that of all these there were only twenty-four, and the great majority of them were small vessels, in which it was *even alleged* that the cause was a failure in identifying the distinctive characteristic of some one of the Northern lighthouses, and in one-third of those cases the sailors were foreigners, and made such glaring mistakes as taking a fixed for a revolving light. It is scarcely more probable that in many of these cases they did not confound the characteristics at all, but really did not know what they were. But, waving all these considerations, there were after all only about 1 per cent. of all the wrecks which were alleged to have been caused by mistaking one light for another.

Power of Coloured Lights.—Experiments, and particularly those of M. Beryand, have shown that red of the same initial power as white penetrates a fog to a greater distance than the white, owing to the red rays not being so much dispersed by refraction. Experiments made at Edinburgh in 1868 show that a light should, before passing through red glass, have four and a half times the initial power of a white light. The same results have since been obtained by M. Allard of Paris.

An objection to all coloured lights is the fact that some persons are unable to detect any difference between certain colours. According to the experiments of Professor Halmgren on sixty to seventy thousand persons in Europe and America, about 4.5 per cent. are congenitally colour-blind, and the commonest form of this defect is inability to distinguish between red and green, which are the only tones employed for lighthouse distinctions. This objection, however, must gradually lose its weight, as the Board of Trade have now adopted the "colours test" as part of their examinations for certificates in navigation.

Distribu-
tion of
light.

Distribution of Lights on a Coast.—Mr Alan Stevenson gives the following as a few of the chief considerations which should guide us in the selection of sites and characteristic appearances of the lighthouses to be placed on a line of coast.

"1. The most prominent points of a line of coast, or those first made on over-sea voyages, should be first lighted, and the most powerful lights should be adapted to them, so that they may be discovered by the mariner as soon as possible before they reaching land."

"2. So far as is consistent with due attention to distinction, revolving lights of some description, which are necessarily more powerful than fixed lights, should be employed at the outposts on a line of coast."

"3. Lights of precisely identical character and appearance should not, if possible, occur within a less distance than 100 miles of each other on the same line of coast which is made by over-sea vessels."

"4. In all cases the distinction of colour should never be adopted except from absolute necessity."

"5. Fixed lights and others of less power may be more readily adapted in narrow cases, because the range of the lights in such situations is generally less than that of open sea-lights."

"6. In narrow cases also the distance between lights of the same appearance may often be safely reduced within much lower limits than is desirable for the greater sea-lights. Thus there are many instances in which the distance separating lights of the same

character need not exceed 60 miles, and peculiar cases occur in which even a much less separation between similar lights may be sufficient."

"7. Lights intended to guard vessels from reefs, shoals, or other dangers should, in every case where it is practicable, be placed seaward of the danger itself, so it is desirable that easen be enabled to make the lights with confidence."

"8. Views of economy in the first cost of a lighthouse should never be permitted to interfere with placing it in the best possible position, and, when funds are deficient, it will generally be found that the wise course is to delay the work until a sum shall have been obtained sufficient for the erection of the lighthouse on the best site."

"9. The elevation of the lantern above the sea should not, if possible, for sea-lights, exceed 200 feet, and about 150 feet is sufficient, under almost any circumstances, to give the range which is required. Lights placed on high headlands are subject to be frequently wrapped in fog, and are often thereby rendered useless, at times when lights on a lower level might be perfectly efficient. But this rule must not, and indeed cannot, be strictly followed, especially on the British coast, where there are so many projecting cliffs, which, while they subject the lights placed on them to occasional obstruction by fog, would also entirely and permanently hide from view lights placed on the lower land adjoining them."

"10. The best position for a sea-light ought rarely to be neglected for the sake of the more immediate benefit of some neighbouring port, however important or influential; and the interests of navigation, as well as the true welfare of the port itself, will generally be much better served by placing the sea-light where it ought to be, and adding, on a smaller scale, such subsidiary lights as the channel leading to the entrance of the port may require."

"11. It may be held as a general maxim that the fewer lights that can be employed in the illumination of a coast the better, not only on the score of economy, but also of real efficiency. Every light needlessly erected may, in certain circumstances, become a source of confusion to the mariner, and in the event of another light being required in the neighbourhood, it becomes a deduction from the means of distinguishing it from the lights which existed previous to its establishment."

"12. Distinctions of lights, founded upon the minute estimation of intervals of time between flashes, and especially on the measurement of the duration of light and dark periods, are less satisfactory to the great majority of coasting seamen, and are more liable to denigration by atmospheric changes, than those distinctions which are founded on what may more properly be called the characteristic appearance of the lights, in which the times for the recurrence of certain appearances differ so widely from each other as not to require for their detection any very minute observation in a stormy night. Thus, for example, flashing lights of five seconds' interval, and revolving lights of half a minute, one minute, and two minutes, are much more characteristic than those which are distinguished from each other by intervals varying according to a slower series of 8", 10", 20", 40", &c."

"13. Harbour and local lights, which have a circumscribed range, should generally be fixed instead of revolving, and may often, for the same reason, be easily distinguished by coloured media. In many cases also, where they are to serve as guides into a narrow channel, the leading lights which are used should, at the same time, be so arranged as to serve for a distinction from any neighbouring lights."

Table of Distances at which Objects can be seen at Sea, according to Distances to their respective elevations, and the elevation of the eye of the observer.

Heights in Feet	Distances in Geographical or Nautical Miles	Heights in Feet	Distances in Geographical or Nautical Miles	Heights in Feet	Distances in Geographical or Nautical Miles
5	3.098	70	9.098	210	19.14
10	3.028	75	9.063	220	19.67
15	4.448	80	10.207	230	20.19

Floating Lights
Prior to 1897 the only kind of floating light was a ship with small lanterns suspended from the masts or spars. The life

Lanterns. *Lanterns* are generally constructed of diagonally framed astragals (fig 77) to avoid the obstruction of light in any one azimuth as would be the case with dioptric fixed light apparatuses were vertical astragals used. The astragals are made of gun-metal, having a tensile strain of 38,000 lb to the square inch; the dome is made of copper plates rivetted

together, and the glass is the best plate $\frac{1}{2}$ inch thick. *Slim paces* are kept at hand which can be applied in a few minutes in the event of a pane being broken, which sometimes occurs from large hot droppings against the window and by stones thrown up from the faces of ships, by the wind and by stones thrown up from the faces of ships, by the wind and during storms. Mr Douglas's cylindrical or helical lanterns (fig. 73) have steel astas, galls, and the panes, which are also cylindrical, are $\frac{1}{2}$ inch thick.

Lighting Conductors — Each lightning tower is furnished with a copper lightning conductor consisting of a 2 inch copper rod or wire rope. These conductors terminate about 18 inches above the top of dome of lantern in a leaded shape with two platinum points, the lower end bolted are furnished with large copper ear plates is sunk into most earth or into the sea. The conductor is put into metallic connection with all large masses of metal outside or inside the lightroom. See **ILLUSTRATIONS**.

Machinery — revolving lights are propelled by clock-work. Machinery is of the simplest and lightest design. The machines are provided with a maintaining power which keeps the apparatus moving while the machine is being wound up, and a bell is attached which rings to warn the keepers when the machine requires winding up. A clock face is also attached which keeps time with the lightroom clock when the apparatus is revolving at the proper speed.

Fig 71 — Diagonal Lantern

Fig 72 — Helical Lantern

Masking Screens.—For the purpose of cutting off sharply the light Masking porcelain from any fixed light apparatus, the late Mr. J. M. Bailett screens devised what he called jadal masking screens. These screens, which are in use at several lighthouses where the runway for ships is narrow, consist of a series of thin plates placed with thin edges towards the apparatus, and with such a distance between them, and of such a length as will seem to cut only rays having the desired divergence *eye* pass through between them.

With revolving lights it is not possible to effect a "cut-off" as in the case of fixed lights, on any particular bearing, for the direction of the axis of the luminous beam projected by the lens or reflector is being continually changed in the horizontal plane by the revolution of the frame on which it is fixed. Sir Stevenson's mode of effecting a cut-off is by the use of a curved glass screen, and a coloured glass slide outside the revolving apparatus and on the safe side of the danger area. These screens are fitted with rollers for running on a slightly inclined plane or spiral path. Small projecting rods or snags fixed to the sides of such lens are, in revolving, brought against the edge of the screen, and gradually raise the screen back to its original position. Figure 1 shows the lens revolved, the edge of the danger area the screen has been pushed to the top of the inclined plane, and the full beam of light, coming from the now entirely uncovered lens, points in the required line of cut-off, which is the bearing of the danger area. But whenever the danger is removed the screen is gradually lowered by the action of the rods or snags, so as to free it from the pressure it immediately runs back again to its original position in front of the lens, so as to prevent any of the light being now sent seawards. By this continued reciprocative movement of the screen, as lens after lens comes round, the same effect will be successively produced, and the light will be cut off in the required direction of rotation, so that the flashes can never be seen within the danger area.

Mathematical investigations and formulae for constructing the Mathematical instruments for lighthouses will be found in the books mentioned by Alan Stevenson, Swan, Chance, Nehls, Reynard, formulae Allard, &c. to which the reader is referred.

Libraire – second, *Narrative of the Edgemoor Lightships*, London, 1798, Latera 18; Stevens, *Account of the Bell Rock Lightship*, Edinburgh, 1824, 1798, 1824, 1825, 1826, 1827, 1828, 1829, 1830, 1831, 1832, 1833, 1834, 1835, 1836, 1837, 1838, 1839, 1840, 1841, 1842, 1843, 1844, 1845, 1846, 1847, 1848, 1849, 1850, 1851, 1852, 1853, 1854, 1855, 1856, 1857, 1858, 1859, 1860, 1861, 1862, 1863, 1864, 1865, 1866, 1867, 1868, 1869, 1870, 1871, 1872, 1873, 1874, 1875, 1876, 1877, 1878, 1879, 1880, 1881, 1882, 1883, 1884, 1885, 1886, 1887, 1888, 1889, 1890, 1891, 1892, 1893, 1894, 1895, 1896, 1897, 1898, 1899, 1900, 1901, 1902, 1903, 1904, 1905, 1906, 1907, 1908, 1909, 1910, 1911, 1912, 1913, 1914, 1915, 1916, 1917, 1918, 1919, 1920, 1921, 1922, 1923, 1924, 1925, 1926, 1927, 1928, 1929, 1930, 1931, 1932, 1933, 1934, 1935, 1936, 1937, 1938, 1939, 1940, 1941, 1942, 1943, 1944, 1945, 1946, 1947, 1948, 1949, 1950, 1951, 1952, 1953, 1954, 1955, 1956, 1957, 1958, 1959, 1960, 1961, 1962, 1963, 1964, 1965, 1966, 1967, 1968, 1969, 1970, 1971, 1972, 1973, 1974, 1975, 1976, 1977, 1978, 1979, 1980, 1981, 1982, 1983, 1984, 1985, 1986, 1987, 1988, 1989, 1990, 1991, 1992, 1993, 1994, 1995, 1996, 1997, 1998, 1999, 2000, 2001, 2002, 2003, 2004, 2005, 2006, 2007, 2008, 2009, 2010, 2011, 2012, 2013, 2014, 2015, 2016, 2017, 2018, 2019, 2020, 2021, 2022, 2023, 2024, 2025, 2026, 2027, 2028, 2029, 2030, 2031, 2032, 2033, 2034, 2035, 2036, 2037, 2038, 2039, 2040, 2041, 2042, 2043, 2044, 2045, 2046, 2047, 2048, 2049, 2050, 2051, 2052, 2053, 2054, 2055, 2056, 2057, 2058, 2059, 2060, 2061, 2062, 2063, 2064, 2065, 2066, 2067, 2068, 2069, 2070, 2071, 2072, 2073, 2074, 2075, 2076, 2077, 2078, 2079, 2080, 2081, 2082, 2083, 2084, 2085, 2086, 2087, 2088, 2089, 2090, 2091, 2092, 2093, 2094, 2095, 2096, 2097, 2098, 2099, 2100, 2101, 2102, 2103, 2104, 2105, 2106, 2107, 2108, 2109, 2110, 2111, 2112, 2113, 2114, 2115, 2116, 2117, 2118, 2119, 2120, 2121, 2122, 2123, 2124, 2125, 2126, 2127, 2128, 2129, 2130, 2131, 2132, 2133, 2134, 2135, 2136, 2137, 2138, 2139, 2140, 2141, 2142, 2143, 2144, 2145, 2146, 2147, 2148, 2149, 2150, 2151, 2152, 2153, 2154, 2155, 2156, 2157, 2158, 2159, 2160, 2161, 2162, 2163, 2164, 2165, 2166, 2167, 2168, 2169, 2170, 2171, 2172, 2173, 2174, 2175, 2176, 2177, 2178, 2179, 2180, 2181, 2182, 2183, 2184, 2185, 2186, 2187, 2188, 2189, 2190, 2191, 2192, 2193, 2194, 2195, 2196, 2197, 2198, 2199, 2200, 2201, 2202, 2203, 2204, 2205, 2206, 2207, 2208, 2209, 2210, 2211, 2212, 2213, 2214, 2215, 2216, 2217, 2218, 2219, 2220, 2221, 2222, 2223, 2224, 2225, 2226, 2227, 2228, 2229, 2230, 2231, 2232, 2233, 2234, 2235, 2236, 2237, 2238, 2239, 2240, 2241, 2242, 2243, 2244, 2245, 2246, 2247, 2248, 2249, 2250, 2251, 2252, 2253, 2254, 2255, 2256, 2257, 2258, 2259, 2260, 2261, 2262, 2263, 2264, 2265, 2266, 2267, 2268, 2269, 2270, 2271, 2272, 2273, 2274, 2275, 2276, 2277, 2278, 2279, 2280, 2281, 2282, 2283, 2284, 2285, 2286, 2287, 2288, 2289, 2290, 2291, 2292, 2293, 2294, 2295, 2296, 2297, 2298, 2299, 2300, 2301, 2302, 2303, 2304, 2305, 2306, 2307, 2308, 2309, 2310, 2311, 2312, 2313, 2314, 2315, 2316, 2317, 2318, 2319, 2320, 2321, 2322, 2323, 2324, 2325, 2326, 2327, 2328, 2329, 2330, 2331, 2332, 2333, 2334, 2335, 2336, 2337, 2338, 2339, 2340, 2341, 2342, 2343, 2344, 2345, 2346, 2347, 2348, 2349, 2350, 2351, 2352, 2353, 2354, 2355, 2356, 2357, 2358, 2359, 2360, 2361, 2362, 2363, 2364, 2365, 2366, 2367, 2368, 2369, 2370, 2371, 2372, 2373, 2374, 2375, 2376, 2377, 2378, 2379, 2380, 2381, 2382, 2383, 2384, 2385, 2386, 2387, 2388, 2389, 2390, 2391, 2392, 2393, 2394, 2395, 2396, 2397, 2398, 2399, 2400, 2401, 2402, 2403, 2404, 2405, 2406, 2407, 2408, 2409, 2410, 2411, 2412, 2413, 2414, 2415, 2416, 2417, 2418, 2419, 2420, 2421, 2422, 2423, 2424, 2425, 2426, 2427, 2428, 2429, 2430, 2431, 2432, 2433, 2434, 2435, 2436, 2437, 2438, 2439, 2440, 2441, 2442, 2443, 2444, 2445, 2446, 2447, 2448, 2449, 2450, 2451, 2452, 2453, 2454, 2455, 2456, 2457, 2458, 2459, 2460, 2461, 2462, 2463, 2464, 2465, 2466, 2467, 2468, 2469, 2470, 2471, 2472, 2473, 2474, 2475, 2476, 2477, 2478, 2479, 2480, 2481, 2482, 2483, 2484, 2485, 2486, 2487, 2488, 2489, 2490, 2491, 2492, 2493, 249

LIGHTING, ELECTRIC. Artificial light is generally produced by raising some body to a high temperature. If the temperature of a solid body be greater than that of surrounding bodies it parts with some of its energy in the form of radiation. Whilst the temperature is low these radiations are not of a kind to which the eye is sensitive; they are exclusively radiations less refrangible and of greater wave-length than red light, and may be called infra-red. As the temperature is increased the infra-red radiations increase, but presently there are added radiations which the eye perceives as red light. As the temperature is further increased, the red light increases, and yellow, green, and blue rays are successively thrown off. On pushing the temperature to a still higher point, radiations of a wave-length shorter even than violet light are produced, to which the eye is insensitive, but which act strongly on certain chemical substances; these may be called ultra-violet rays. It is thus seen that a very hot body in general throws out rays of various wave-length, our eyes, it so happens, being only sensitive to certain of these, viz., those not very long and not very short, and that the hotter the body the more of every kind of radiation will it throw out, but the proportion of short waves to long waves becomes vastly greater as the temperature is increased. The problem of the artificial production of light with economy of energy is the same as that of raising some body to such a temperature that it shall give as large a proportion as possible of those rays which the eye happens to be capable of feeling. For practical purposes this temperature is the highest temperature we can produce. As an illustration of the luminous effect of the high temperature produced by converting other forms of energy into heat within a small space, consider the following statements. 120 cubic feet of 15 candle gas will, if burned in ordinary gas burners, give a light of 360 standard candles for one hour. The heat produced by the combustion is equivalent to about 60 million foot-pounds. If this gas be burned in a gas-engine, about 8 million foot-pounds of useful work will be done outside the engine, or four horse-power for one hour. This is sufficient to drive an "A" Gramme machine for one hour; the energy of the current will be about 6,400,000 foot-pounds per hour, about half of which, or only 3,200,000 foot-pounds, is converted into radiant energy in the electric arc, but this electric arc will radiate a light of 3000 candles when viewed horizontally, and two or three times as much when viewed from below. Hence 3 million foot-pounds changed to heat in the electric arc may be said roughly to affect our eyes six times as much as 60 million foot-pounds changed to heat in an ordinary gas burner.¹ Owing to the high temperature at which it remains solid, and to its great emissive power, the radiant body used for artificial illumination is nearly always some form of carbon.

The consideration of electric lighting naturally divides into two parts—the production of suitable electric currents, and the conversion of the energy of such currents into radiations. Although electric lights were first produced from currents generated by batteries, they have only attained commercial importance by the use of machines for converting mechanical energy into electric current.

Dynamo-Electric Machines.—In the widest sense a dynamo-electric machine may be defined as an apparatus for converting mechanical energy into the energy of electrostatic charge, or mechanical power into its equivalent electric current through a conductor. Under this definition would be included the electrophorus and all frictional machines; but the term is used in a more restricted sense

for those machines which produce electric currents by the motion of conductors in a magnetic field, or by the motion of a magnetic field in the neighbourhood of a conductor. The general laws of electromagnetic induction need not be set forth here, as they are fully explained in the article **ELECTRICITY**, they will be assumed in all that follows. Since, if the current in a closed circuit be in one direction when the number of lines of force is increasing, it will be in the opposite direction when they are diminishing, it is clear that the current in each part of the circuit which passes through the magnetic field must be alternate in direction. Hence also the current in the wire outside the machine must also be alternate, unless something of the nature of a commutator be employed to reverse the connections of the internal wires, in which the current is induced, and the external circuit. We have then broadly two classes of dynamo-electric machines—the simplest, the alternate current machine,² where no commutator is used; and the continuous current, in which a commutator is used to change the connections to the external circuit just at the moment when the direction of the current would change.

The mathematical theory of alternate current machines is comparatively simple.³ Let τ be the period of the machine, that is, the time taken to move the armature from one position to the next exactly similar position, t θ , in a Siemens alternate current machine of sixteen magnets on each side, one-eighth of the time of revolution; let γ be the coefficient of self-induction of the whole circuit, and R the resistance of the whole circuit; and let t denote the time at any instant counting from any epoch as initial, and I the magnetic induction at time t multiplied by the number of convolutions. The electromotive force in the circuit at time t will be

$$\frac{dI}{dt},$$

and the equation of the current will be

$$\gamma \frac{dI}{dt} + RI = Z \sin \frac{t - t_0}{\tau},$$

where Z is the current. Now I may be expressed in the form

$$I = A \sin 2\pi \frac{t - t_0}{\tau},$$

where A , and t_0 are constants for the machine with given excitation of the fixed magnets. Hence

$$\gamma \frac{dI}{dt} + RI = 2\pi \frac{\gamma A}{\tau} \cos 2\pi \frac{t - t_0}{\tau},$$

$$= Ce \frac{-R}{\gamma} + 2\pi \frac{\gamma A}{\tau} \frac{\cos 2\pi \frac{t - t_0}{\tau} - \frac{t - t_0}{\tau}}{\sqrt{\left(\frac{2\pi \gamma}{\tau}\right)^2 + R^2}},$$

where

$$\tan \frac{2\pi \tau}{\tau} = \frac{2\pi \gamma}{RT}$$

The term $Ce \frac{-R}{\gamma}$ is unimportant except just after closing the circuit. In the Siemens machine M Joubert states that the only

³ Proc. Inst. C. E., li, 69; Report from the Select Committee on Electric Lighting, 1879.

important term is that of longest period. Hence, properly choosing the epoch, we write

$$\alpha = \frac{2\pi h}{T} \frac{\cos 2\pi \frac{t-\tau}{T}}{\sqrt{\left(\frac{2\pi\gamma}{T}\right)^2 + R^2}},$$

where

$$\tan \frac{2\pi\tau}{T} = \frac{R\gamma}{2\pi\gamma}.$$

Hence we see the current is diminished either by increasing γ or increasing R , also that the moment of reversal of current is not coincident with that of no electromotive force, but occurs after that time by an amount depending on the relative magnitudes of γ and R . This explains in a general way what is known as the lead of the brushes in a continuous current machine. If we wished to apply a commutator to the Siemens alternate current machine for the purpose of producing an external current constant in direction, the charge effected by the commutator should occur at an epoch after that of greatest electromotive force, an epoch which, with varying external resistance or varying speed, will depend on the resistance and speed.

The power of the current is $R\alpha^2$, and the energy in any considerable time, Θ , is

$$\Theta R \frac{2\pi h^2 \Lambda^2}{T^2} \frac{1}{\left(\frac{2\pi\gamma}{T}\right)^2 + R^2},$$

which shows that most power will be required to drive the machine when

$$R = \frac{2\pi\gamma}{T}.$$

In what precedes it has been assumed that the copper wires are the only conducting bodies moving in the magnetic field. In most cases the moving wire coils of these machines have iron cores, the iron being in some cases solid, in others more or less divided. It is found that if such machines are run on open circuit the iron becomes hot, very much hotter than when the current of the copper wire is closed; in some cases the phenomenon is so marked that the machine actually takes more to drive it when the current is quite open than when the machine is short-circuited. The explanation is that on open circuit currents are induced in the iron cores, but that when the copper coils are closed the current in the latter by its induction diminishes the current in the iron. The effect of currents in the iron cores is not alone to waste energy and heat the machine, the current produced is also actually less for a given intensity of field and speed of revolution. The cure of the evil is to subdivide the moving iron as much as possible in directions perpendicular to those in which the current tends to circulate.

Continuous or Direct Current Machines.—It has been shown that to produce a continuous current a commutator is needed. If there is but a single wire in the armature, or if there are more than one, but all are under maximum electromotive force at the same time, the current outside the machine, though always in the same direction, will be far from uniform. This irregularity may be reduced to any extent by multiplying the wires of the armature, giving each its own connexion to the outer circuit, and so placing them that the electromotive force attains a maximum successively in the several circuits. A practically uniform electric current was first commercially produced with the ring armature of Pacinotti as perfected by Gramme. Suppose a straight bar electromagnet surrounded by a coil of copper wire from end to end. Let the electromagnet be bent with the copper wire upon it until its ends meet and it forms an annulus or anchor ring. Let the two ends of the copper wire be connected, so that the iron core is surrounded by an endless copper wire, and you have the Pacinotti or Gramme ring. This ring rotates about its axis of figure between two diametrically opposed magnetic poles of opposite name. The ring may at any instant be supposed divided in halves by a diameter perpendicular to the diameter joining the centre of the poles. Equal and opposite electromotive forces act on the copper wire of the two halves, giving two opposite electric poles half way between the magnetic poles. If electric connexions could be maintained with these two points as the ring revolves, a continuous current would be drawn off. In practice this

is only approximated to. The copper wire is divided into a series of equal sections, and at the point of junction of each section with its neighbour a connexion is made with a plate of a commutator, having as many divisions as there are divisions of the copper coil. Collecting brushes bear upon the commutator plates, which are connected to the coil nearest to the point of maximum potential. Owing to the self-induction and mutual induction of the several coils of the armature, this point is displaced in the direction of rotation when a current is being drawn off, to an extent greater as the current is greater in relation to the strength of the magnetic field. The magnetic field in the Gramme and other continuous dynamo-electric machines may be produced in several ways.¹ Permanent magnets of steel may be used, as in the smaller machines now made, and in all the earlier machines; these are frequently called magneto-machines.² Electromagnets, excited by a current from a smaller dynamo-electric machine, were introduced by Wilde; these may be described shortly as dynamos with separate exciters. The plan of using the whole current from the armature of the machine itself for exciting the magnets was proposed almost simultaneously by Siemens, Wheatstone, and S. A. Varley.³ For some purposes it is advantageous to divide the current from the armature, sending the greater part through the external circuit, and a smaller portion through the electromagnet, which is then of very much higher resistance, as the electromagnet is a shunt to the external circuit. Machines so arranged are sometimes called shunt dynamos.⁴ The last two arrangements depend on residual magnetism to initiate the current, and below a certain speed of rotation give no practically useful electromotive force.

In discussing the comparative efficiency of dynamo-machines there are two points to be examined—(1) how much of the power applied is converted into energy of current in the whole circuit, whether external or in the wires of the armature or of the electromagnets, and (2) how much of the power is available outside of the machine. The

practical sources of loss are friction of bearings, and of the brushes on the commutator, electric currents induced in the iron of the machine, production of heat in the copper wire of the armature due to its resistance, and production of heat in the wire of the electromagnet due to its resistance. There is also a certain loss in sparks upon the commutator. The currents in the iron are reduced by dividing the iron by insulating surfaces perpendicular to the electromotive force tending to produce such currents. The loss by resistance of wire in armature and magnets greatly depends on the dimensions of the machine. For imagine two exactly similar dynamo-electric machines, the one being n times the dimensions of the other, we have the following relations between them, assuming the same magnetic field per square centimetre, and the same speed of rotation:—

The electric resistances of the several parts are as $1:n$;
The electromotive force of the armature as n^2 ;
Current round magnets required to produce the field as n .

Thus the work wasted in heating the wire of the electromagnets varies as the linear dimensions of the machine. The current which the armature can carry with safety to the insulation will increase more rapidly than the linear dimensions of the machines, but less rapidly than the square of the linear dimensions. If the current vary as the linear dimensions n , the whole electric work done by the machine will vary as its weight n^3 , and the work wasted in the coils both of the electromagnets and of the armature will only vary as n ,—showing a great theoretic advantage in favour of the larger machines.

Electric Lamps. Incandescent Lamp.—The simplest way of obtaining light from an electric current is by passing it through a considerable resistance in such small compass that the conductor becomes intensely hot. It is of course necessary that the conductor shall be able to endure a very high temperature without injury. Indium and platinum-iridium wire have been employed, but are too expensive for commercial use. Hitherto the only available substance is carbon, in the form of a thread or filament. This carbon must be protected from the air by enclosing it in a glass globe from which every trace of air has been removed. An electric current passing through a carbon filament obeys Ohm's law, as through a metallic wire. But in metals the resistance increases as the temperature rises, in carbon it diminishes.¹ The filament or thread of carbon being enclosed in a vacuum space, the energy of current converted into heat in the filament only leaves it in the shape of radiations. To light economically, it is necessary to heat the filament to such a temperature that the greatest possible proportion of these radiations shall belong to that part of the spectrum to which the eye is sensitive, i.e., to the highest temperature the filament will stand. The fundamental problem of incandescent electric lighting is to produce a carbon thread the substance of which shall permanently stand the highest possible temperature, to make good electrical connexion between the ends of the filament and the conducting wires, and above all to secure that the thread shall be uniform throughout its length, for the current which can be safely used is limited by the weakest point of the filament. Several inventors have recently succeeded in meeting these

conditions, but their relative merit and priority cannot be discussed here.²

Semi-incandescent Lamp.—The lamps of Werdemann, Reynier, and Joel are intermediate between arc lamps and incandescent lamps, and present the distinctive advantages of neither.³

Arc Lights.—Sir Humphry Davy discovered that if two pieces of carbon were placed in contact with each other, and the current from a battery of a sufficient number of elements were passed from one piece to the other, the current did not cease when the carbons were slightly parted, but that the current passed across the intervening space, causing an intensely high temperature and consequently brilliant light. The pieces of carbon gradually burned away, the positive carbon being consumed more rapidly than the negative. When an electric current passes through a conducting solid body maintained at a constant temperature, the difference of potential on the two sides of the body has a constant ratio to the current passing through, this constant ratio is known as the electric resistance of the body at its then temperature. No such constant ratio exists in the case of the electric arc. If you increase the current passing between two carbons at a small distance apart, you do not materially change the difference of potential at the two ends of the electric arc. It is, therefore, not strictly appropriate to speak of the resistance of the electric arc; the appropriate constant, or approximate constant, for an electric arc is the difference of potential between the two sides of the arc.⁴ However near the carbons approach without touching, this does not fall below a certain minimum value, and as the carbons are separated its value increases. In ordinary practice with continuous currents the potential of the electric arc may be taken as ranging from 35 to 45 volts. If the current in amperes be multiplied by the difference of potential in volts, and the product be divided by 746, we have the power used in the arc itself in horse-power, that is, the power effectively used in lighting. The mechanism of an electric lamp has two functions to perform, it has first to bring the carbons into contact and then part them, or simply part them if they are initially in contact when the light is started, or when it is accidentally extinguished (this is called striking the arc); it has also to bring the carbons together as they are consumed. The former function is always accomplished by an electromagnet or solenoid. In the electric candles, e.g., those of Jablonskoff, Rapieff, Wilde, or Siemens, the carbons are approximately parallel, and they burn down as does a candle,—the arc being forced to the ends of the carbons by the repulsion of the current in the carbons on the electric arc.⁵ In the ordinary arc lamps the carbons have their axes in the same line, and their approach or recession must be controlled by the current passing through, by the difference of potential, or by both combined. When the same current passes through a succession of lamps in series, it is clear that the regulation cannot be by the

¹ The application of incandescent lighting on a large scale has been thoroughly worked out in all its details by Edison. For a description of the whole system see *Engineering*, xxxiii. 225, 250, 305, 407.

current alone, as this is the same for all the lamps, and might be maintained constant by the adjustment of any one only of the lamps. When lamps are burned in series, it is essential that the difference of potential shall be an element in the control. This is done by using an electromagnet bound by fine wire so as to have a resistance of some hundreds of ohms, and connecting it to the two sides of the arc. In the Siemens differential lamp, and in some others, a potential or shunt coil and a current coil oppose each other, as the arc lengthens the current becomes less, and the potential greater, each acting to cause the carbons to approach. It will be seen that the possible combinations of mechanisms and electromagnets for adjusting an electric arc are endless, and so also are the patents for such combinations.¹ When an alternate current is used for an electric arc, the phenomena are much more complicated, owing to the difference of potential being a discontinuous function of the time. The difference of potential will be (say) 40 volts in one direction for a certain fraction less than half of the periodic time of the current, the current then entirely ceases, generally for a finite time, and is then reversed with a sudden reversal of difference of potential.² The work done in the arc is measured by the time integral of the product of difference of potential and current passing. A knowledge of neither the mean strength of the current, nor of the difference of potential, nor of both, gives the means of ascertaining the work done in an arc with alternate current. The only satisfactory electrical method is the quadrant electrometer suitably connected, and this is open to the objection that a considerable resistance must be introduced into the circuit.

Electric Light Measurements.—Under this head we content ourselves with a warning. A bare statement that an electric arc light is of so many candle power really conveys no accurate information at all. The light from an electric arc differs greatly in colour from that of a candle,³ a given arc light may have three thousand times as much red of a certain wave-length as a standard candle has of the same wave-length, but ten thousand times as much green light. Any one will admit that green light is not measurable in terms of red light; a mixture of red and green is not

measurable in terms of another mixture in which the proportions of the colours are wholly different. Again, the intensity of the light obtained from an arc light depends greatly on the direction in which it is viewed.⁴ Neither of these considerations applies in the same degree to incandescent lamps. (J. HO.)

LIGHTNING. See METEOROLOGY and THUNDER-STORMS.

LIGHTNING CONDUCTOR, or LIGHTNING ROD (*Paratonnerre, Blitzableiter*), is the name usually given to apparatus designed to protect buildings or ships from the destructive effects of lightning. The title, alike in English, French, and German, is misleading; for, when properly constructed, lightning rods serve rather to prevent the occurrence than to ward off the effects of a flash of lightning. Damping the enemy's powder would be a most efficient precaution against cannon-shot, but it would be very inappropriately termed fortification. When a conductor charged with electricity is brought near to another conductor connected with the earth, it induces on it a charge of the opposite kind of electricity. The result is an attractive force which tends to bring the conductors nearer to one another, and to augment the electric density on their opposed surfaces. When the density is sufficiently great, there is rupture of the dielectric (air) between the conductors, and the disruptive discharge takes place as an electric spark. If one of the conductors have projecting points or angles, the electric density is usually much greater at such places than over the rest of the surface. But, though the density is great at such places, the charge on them is usually small, and the discharge takes place in an almost continuous manner by a brush or glow. When, for instance, a large conductor, connected with an electric machine, is giving a rapid succession of bright sparks to a ball connected with the ground, the sparks cease as soon as a pointed wire, connected with the ground, is held in the vicinity of the conductor. No discharge is heard, but in the dark a faint glow is seen at the end of the wire, which continues as long as the machine is turned. Remove the wire and the sparks instantly recommence. This glow is known to sailors as St Elmo's (San Telmo's) fire, in old days Castor and Pollux (*Plin., H. N., ii. 37*). Suppose now one of the conductors to be a thundercloud, the other the surface of the earth, the discharge will usually take place between the places of greatest surface density, and it will in general be the more gradual as these are more pointed, and of less capacity. Hence Franklin's idea of furnishing buildings or other prominent objects with a projecting metal spike well connected with the ground, for the purpose of preventing a lightning discharge by substituting for it what is practically a continuous electric current.

To effect this object thoroughly, only three things are necessary:—(1) the points should so project from the building or ship, to be protected as to prevent any great development of electric density elsewhere than on themselves; (2) they should be effectually connected with the earth; (3) the connecting rod ought to be so good a conductor as not to be injured even by a powerful electric discharge.

The first of these conditions is realized by making the rod branch out to all the salient portions of the building or ship, and furnishing it with points projecting beyond each of them. No general rule can be laid down as to the extent of the region protected by a single point, though it may usually be assumed with safety that the region extends throughout a vertical cone whose vertex is at the point,

and whose semivertical angle is about 45° . This is probably not true if the point be very high,—on the top of a tall chimney or tower, for instance. Objects not far from the base of such a protected tower, and within the cone just described, have occasionally been damaged by lightning.

The second condition is easily fulfilled in towns by connecting the lower end of the rod with the iron gas and water-mains, which form an excellent "earth," as it is technically called. Water-pipes, being usually joined with metallic-lead-washers, are preferable to gas-pipes, which are usually put together with white lead. This condition is also easy to secure in ships and in lighthouses, where large metal plates (in the case of a ship, the copper sheathing is precisely what is required) can easily be permanently immersed in sea-water. In country houses it is usually more difficult to obtain a proper earth. Plates and tubes of metal, of large surface, buried in ground which is permanently damp, form usually the best arrangement. A well makes a good earth, a carefully constructed water tank (of stone or cement) is not an earth at all.

The third condition, so far as experience can guide us, seems to be effectually realized by making the conductor throughout of iron rod of an inch in diameter, or of copper rod not less in diameter than $\frac{3}{16}$ of an inch. Such rods of equal length have nearly the same conducting power, and therefore would have equal amounts of heat developed in them by a given discharge. But if such a discharge took place, the copper would be heated much more than the iron, in consequence of its smaller mass per foot (the specific heat being approximately the same in the two materials). Hence iron is, in this respect, preferable to copper, if the conducting powers of the rods are equal. Another advantage possessed by the iron rod is that it is much less likely to be wilfully damaged or stolen. Against this may be set the objections that it is easily injured by rust, and is not nearly so flexible as the equivalent copper rod. Conductors are now usually made of wire-rope, so that the question of flexibility is no longer of serious importance; but when iron is used it should always be protected by zinc, *i. e.*, be what is absurdly called "galvanized." Many fantastic forms of lightning rods were devised in consequence of the old erroneous notion that their efficiency depended on their surface and not on their cross section. In reality all conductors of equal length, and of the same material, are equally efficient if their cross sections be equal.¹ Thus, instead of stating the diameter of a rod, we may speak of its weight per foot, and say that a copper conductor should weigh at least about half a pound, and an iron one at least two pounds and a half per foot,—provided the materials be of good conducting quality.

The points need not be very sharp, but they ought to be protected by a coating of platinum or other non-oxidizable metal. And they should be in a group of two or three at the end of each branch of the rod, lest one of them should be fused and impaired in efficiency by an accumulation of electricity so rapid as to make the silent continuous discharge impossible. Joints should be avoided as far as possible; where they are unavoidable they should be made, not by screws or brazing, but by means of a large mass of solder completely enveloping the ends to be connected.

Another point to be carefully attended to is that all large metallic bodies, such as lead or zinc roofing, metal tanks, &c., should be in good conducting connexion with the rod, so as to prevent discharges of electricity inside the ship or building. In many buildings we see the lightning rods

attached by means of glass or porcelain insulators, such as are employed for telegraph wires. This is a perfectly needless, expensive, and possibly dangerous practice.

The literature of this subject is very extensive, as may be seen from Ronald's *Catalogue of Works on Electricity*. The reader may also consult Anderson on *Lightning Conductors* (1880), and the *Report of the Lightning-Rod Conference* (1882). In the latter work will be found abstracts of many valuable papers, especially the reports on lightning-rods made to the French Academy by some of its most distinguished members, including Coulomb, Laplace, Poussin, Gay Lussac, Fresnel, Pouillet, Gagnard de la Tour, Regnault, &c. There will also be found hints about some of the most ludicrous devices employed by men ignorant of the laws of electrical phenomena. One of the most singular of these was the so-called "Repeller." A lightning-rod, in all respects sufficient, was wont to be capped by a piece of glass like a thick soda-water bottle, inverted upon its point. The effect of this could only have been to prevent the possibility of the silent discharge, to produce which is the proper function of the rod, and to make probable a lightning flash, just as if the rod had been terminated by a ball instead of a point. One of these dangerous monuments of ignorance was removed from a British lighthouse within the last ten years. In an Irish lighthouse, which was recently examined after suffering serious damage, it was found that the lower end of the lightning-rod was jammed into the solid rock—a truly original form of "earth."

In 1870 Clerk Maxwell suggested to the British Association the idea (based on Faraday's experiments) of protecting a building from the effects of lightning by surrounding it with a sort of cage of rods or stout wire. Here an "earth" would not be absolutely required. The present writer had some months previously suggested the same idea in a Report to the Board of Northern Lights. It is possible, though not certain, that this form of defence might be useful against globe-lightning, which undoubtedly occurs, and against which ordinary lightning-rods would probably be of little use.

These brief remarks contain all that is yet known to be necessary to the complete solution of an important practical problem about which many treatises have been written. (P. G. T.)

LIGNITE. See COAL.

LIGNUM VITÆ. See GUAIACUM.

LIGUORI, LIGUORIANISM. The name Liguorianism has been popularly given in the present century to a particular school of moral and devotional theology in the Roman Catholic Church by the controversial opponents of that school, whether themselves Roman Catholics or not. It is derived from the name of one of its principal and most influential exponents, Alfonso Maria de' Liguori, a theologian, saint, and doctor of the Roman Church. In strictness, the term is not accurate, for Liguori was in no sense the founder of the school, nor did he innovate upon, develop, or exaggerate its principles and maxims. He was simply a fair representative of the national type of piety of Italian devotees in his day; and, as a casuist, he was a diligent compiler, whose avowed design was to take a middle course between the two principal varieties of teaching in moral theology current in his own time, avoiding their extremes of severity or laxity. His own words, in the preface to his *Homo Apostolicus*, a work intended for the guidance of priests in hearing confession, explain clearly the intention of his bulkier treatise, the *Theologia Moralitatis*. He says—"When compiling that work, I spent the labour of fifteen years in pursuing and weighing the teaching of very many writers whom I examined, some of whom I found more lenient than is just; . . . while I found others who, strongly disliking such indulgence, fell into the other extreme of excessive rigour. And this was my principal task, to select from such a mass of opinions those decisions which, on the one hand, should uphold the obedience due to the precepts of God and of the church, and on the other should not add burdens which God has not imposed, by hiding every one to that perfection which, through human weakness, is morally impossible to the general body of believers." A brief glance at the names of those casuists whom he cites most frequently, as Covarruvias, Soto, Lessius, Vasquez, Bonacina, the doctors of Salamanca, Sanchez, Diana, &c., shows them to belong to the hundred years between 1580 and 1680, and

¹ Some curious modifications of this statement are introduced when we deal with magnetisable metals, but they are unimportant in practice.

therefore to the period of Jesuit predominance in moral theology, and of the prevalence of those maxims which Pascal lashed in the *Provinciales*, many of which were soon after condemned by Pope Innocent XI. in 1679. But, as Liguori embodies also in his materials the casuistical authors of the succeeding century, who were taught some caution by those mislapses of their predecessors, his works represent the final stage of casuistry in what is accounted a purified and moderate form, and have a yet greater importance, in that they have been accorded an official approval and authorization from the highest authorities of the Roman Catholic Church, such as those of no previous casuist of the post-Reformation era can allage. They are fully sanctioned, encouraged, and recommended for general use amongst the Roman Catholic clergy, and in fact only just fall short of being actually enjoined. Consequently they themselves, and the works based on them by Scavini and Gaume, as also the kindred manual of Gury, are all but universally found in use, and it is thus easy to learn from them what is now the accredited moral theology prevalent throughout the Latin obedience. So much being premised, we may now turn to the life of Liguori himself, and thence to the analysis of the system which he expounds.

Alfonso Maria de' Liguori, son of Giuseppe de' Liguori, a Neapolitan noble, and of Anna Cavaleri de' Brindisi, his wife, was born at Marianella, near Naples, on September 27, 1696. He was educated chiefly at home, though he attended an Oratorian school at Naples for a time, and, as his father desired that he should rise to office in the magistracy, he was especially directed to the study of jurisprudence, both civil and canonical. He took the degree of doctor in this faculty in January 1713, being then little more than sixteen years old. He was called to the bar in due course, and obtained considerable practice, while his biographers dwell much on the high moral tone of the rules he laid down for his guidance in the conduct of professional business. The loss of an important suit in which he was engaged as counsel for a Neapolitan noble against the grand-duke of Tuscany, and in which he had entirely mistaken the force of a leading document, so mortified him that, acting on a temper already disposed towards the monastic life, it induced his withdrawal from the legal profession, which he never resumed after this defeat. He soon adopted the ecclesiastical dress as a candidate for orders, which he received in December 1724, when he entered as a novice into the Congregation of Missions, being ordained priest in December 1726.

He soon became popular as a preacher and as a confessor, obtaining much influence in Naples and its vicinity. In 1732 he founded the "Congregation of the Most Holy Redeemer," usually known as Redemptorists, or, as they are often named, Liguorians, whose special object is the religious instruction of the rural poor and other uneducated classes, establishing the first house of the society, in the form of much opposition, at the little town of Scala, about 8 miles from Salerno. The headquarters were transferred somewhat later to Chieti, and in 1743 to Nocera dei Pagani, which is still the chief house. The confirmation of the rule and institute was obtained from Benedict XIV. in February 1749, and in the following year Liguori, who had previously made some minor literary ventures, published one of his most famous and popular books, *Le Glorie di Maria*, a book intended to promote the cultus of the Blessed Virgin; and in 1753 he issued his yet more celebrated *Moral Theology*, dedicating it to Pope Benedict XIV., expressly as a "via media" treatise. An Italian version of this book, somewhat abridged, recast, and adapted for the use of the clergy, was his next task; and, on this shorter treatise becoming

popular, and a demand for it arising outside of Italy, he translated it into Latin, and issued it in 1766 as the *Homo Apostolicus*.

In 1762, being then sixty-six years of age, he accepted the bishopric of Sant'Agata dei Goti, a small town in the province of Benevento, at the express desire of the pope (though he had several years before refused the archbishopric of Palermo, offered him by the king of Naples), and by a very unusual concession was permitted to retain his superiority of the Redemptorists, governing them by means of a vicar-general. He worked diligently in this sphere of labour for thirteen years, busying himself with practical reforms of various kinds in his diocese, notably in trying to raise the standard of clerical life and work, while not intermitting either his literary pursuits or his efforts to promote the growth of his Redemptorist institute. In 1776, being then seventy-nine years of age, he obtained permission from Pius VI. to resign his bishopric, on the plea of enfeebled health, and retired to the Redemptorist house at Nocera dei Pagani, where he died August 1, 1787, aged nearly ninety-one. He was decreed the rank of "Venerable" very speedily, being so named by Pius VI. in 1796, was beatified by Pius VII. in 1816, canonized by Gregory XVI. in 1839, and finally declared a "Doctor of the Church" by Pius IX., March 11, 1871. He is one of the most copious of the later Roman theologians, and his productiveness extended over a period of thirty years, from the issue of his *Visita to the Blessed Sacrament* in 1747 till the appearance of no fewer than eleven treatises in 1777; but his only writings necessary to be added here to those already named are his treatises *De Usu Moderato Opinionis Probabilis*, 1754, recast and reissued in 1766, *Præcis Confessariorum*, 1766; six apologies in defence of his views on probabilism and of his *Moral Theology*, in the same year, followed by three more in 1768; *Verità della Fede*, against Helvetius and the deists, 1767; *Storia della Breve*, directed chiefly against the Jansenists and Molinists, 1772; *Dissertationi teologiche morali*, 1772; and *Industria pro suprema Pontificia potestate, adversus Justinum Febronium*, in the same year.

He was a man of naturally amiable and gentle disposition, ascetic and self-denying in his personal habits, indefatigably diligent in many forms of activity, and of more than respectable abilities, though with the emotional side of his character in greater relief than its intellectual side. He was learned, as learning was understood amongst the Italian clergy of the 18th century, though altogether lacking in critical faculty, whence he is quite untrustworthy as a controversialist, not only as habitually quoting spurious or interpolated authorities, but by adding matter of his own to amplify genuine quotations which fall short of proving his case. In estimating the nature of his moral teaching, not only have these personal characteristics to be steadily kept in mind, but also the fact that his life exactly synchronizes with that epoch of European history which was the seed-time of the Revolution, and when, owing to reaction from the fervid theological controversies of the 16th and 17th centuries, a general languor, coldness, and indifference towards religious questions reigned in all parts of Western Christendom. It was Liguori's firm belief that only the most lenient and gentle treatment could win back the alienated laity; and consequently, though he professed to steer a middle course between errors of laxity and severity in moral teaching, and fully believed himself to have done so, yet in fact such a treatment was impossible to one who viewed the question as he did. For, while he regarded errors on the side of laxity as pardonable mistakes committed through excess of zeal in winning over penitents, contrariwise he looked on the stricter method of the rigorists, who upheld a loftier

morality, as not merely inexpedient, but as positively and intentionally evil, as designed to make religion odious by making it impossible, and so to prepare the way for the triumph of unbelief. He identified all teaching of the sort with Jansenism, and Jansenism, from its resistance to various pontifical decrees, seemed to him all but equivalent to atheism.

Hence the opinions of rigorist theologians find almost no place in his writings, save for the purpose of censure, since he did not regard them as authorities to be relied on; and accordingly the line he draws is not, what he probably thought it, an intermediate one between rigorism and laxity, but between a greater and a lesser degree of laxity, depending on the working of the principle known as "Probabilism." The meaning of this principle (due to the scholastic form of the Aristotelian dialectic, and thus visible in germ as early as St Thomas Aquinas, though not taking final shape till the writings of Medina, Valencia, Vasquez, and others, mainly, but not exclusively, Jesuits, at the close of the 16th century) is simply this.—when a doubt arises as to the binding force of some divine or human precept in any given case, it is permissible to abandon the opinion in favour of obedience to the law—technically known as the "safe" (*tuta*) opinion—for that which favours non-compliance, provided this laxer opinion be "probable." And by "probable" is meant any judgment or opinion based on some reasonable grounds, though with some doubt that the opposite view is perhaps the true one (Gury, *Theol. Mor.*, vol. i. n. 51). It may be probable in two chief ways,—intrinsically, because of reasons drawn from the nature of the thing itself, or extrinsically, because supported by one or more theologians of repute; and its degree of probability may vary according to a variety of conditions. Casuists are divided into six classes according to their mode of regarding probability.—(1) Rigorists, who lay down that the safer way, that of obedience to the law, is always to be followed; (2) Mitigated Rigorists, or "Tutorists," who holding that the law is always the safer and better way, yet allow that an opinion of the highest intrinsic probability in favour of liberty may sometimes be followed; (3) Probabiliorists, who hold that the law is always to be obeyed unless an opinion clearly very probable (*probabilior*) is opposed to it; (4) Equiprobabilists, who teach that in a balance of opinions the less safe opinion may be lawfully followed, provided it be as probable, or nearly as probable, as its opposite; (5) Moderate Probabilists, according to whom it is lawful to follow the less safe and somewhat less probable opinion, provided it have some degree of real probability, even if the opposite opinion be clearly more probable; (6) Laxists, who hold that even slightly probable opinions may be followed; but, as they were condemned by Innocent XI, they no longer exist as an avowed school, but are still latent under classes 4 and 5.

On further examination, it appears that the right of judging of the *intrinsic* probability of an opinion is restricted to persons of considerable learning, and specially versed in moral theology, since they alone can know that there is not any certain argument in opposition. All other inquirers must fall back on *extrinsic* probability, that is, on what may be called "counsel's opinions." And, in forming a judgment on this basis, the following rules are laid down by F. Gury:—a moderately educated person may accept as probable any opinion which he finds asserted by distinguished theologians of the present day, and may follow even a single author of repute, though teaching contrary to the commonly received view, provided he brings forward some fresh argument, and can urge reasonable pleas against former solutions; while an ignorant man may take the word of any person whom he thinks trustworthy, able, and

learned, that a particular opinion is probable (*Theol. Mor.*, vol. i. n. 54). Some classes of things are, however, excluded by Roman casuists from the operation of this principle; as, for example, all questions relating to matters of faith, in which the very highest degree of probability is not sufficient to excuse from following the safe opinion, which is that of the Roman Church. Liguori's own position is that of an equiprobabilist, and he therefore, as a rule, leans to the laxer side.

Before proceeding to illustrate the exact nature of his teaching by extracts from his works, it is desirable to ascertain what degree of authority attaches to those works in virtue of the position now accorded to him. In the first place, one of the earliest steps in the process of canonization is a strict review of every writing of the candidate proposed, whether published or unpublished. Every single proposition therein must be separately considered, and be judged on its own merits, without taking the author's probable intention into account, and if even one passage be found which fails to stand this test, as containing any moral or theological error, the process is stopped at once, unless proof be adduced that the author had in his lifetime formally and fully retracted the erroneous opinion. But a decree of the Congregation of Rites, confirmed by Pius VII. in 1803, declared that in none of the writings of Alfonso de Liguori was anything found meriting censure, and the testimony of Artico, bishop of Asti, and prince-bishop of the papal household, is that the examination had been unusually severe, that Liguori's system of morality had been discussed more than twenty times, and that the approval of the congregation was perfectly unanimous. Next, in the year 1831, Cardinal Rohan-Chabot, archbishop of Besançon, submitted a case to the cardinal grand penitentiary, desiring to know, whereas the teaching of Liguori's *Moral Theology* was resisted by some persons in his diocese, as too lax, dangerous to salvation, and contrary to the moral law, whether a professor of theology might safely follow and teach the opinions in that work, and further, whether a confessor should be molested for following those opinions in the confessional, solely on the ground that they had been pronounced free from censure by the apostolic see, and without having examined them independently himself. To the former of these questions an affirmative reply was given, to the latter a negative one. Thirdly, in the bull of canonization, issued by Gregory XVI. in 1839, the entire absence of error in Liguori's writings is once more asserted.

So far, no more is implied than the entire orthodoxy and moral soundness of Liguori's writings, vouched for to the ordinary Roman Catholic by the fact of his canonization. And, though the liberty is thereby taken away of directly censuring any proposition in the writings of a saint as doctrinally or morally untenable, yet there is no precise obligation to follow all things contained therein. It is still lawful to challenge the opinions of a saint, if it be done modestly and with the production of strong reasons (Bened. XIV., *De Canoniz.*, ii. 32, 12); but this liberty is very seriously abridged if the saint be also a "Doctor of the Church." For the meaning of that title is that the person who bears it is one who has not merely transmitted the teaching of the church to others, but has taught the church itself (Bened. XIV., *De Canoniz.*, ii. xi. 11), and whose doctrine has consequently been generally followed and authorized by the church. The number of these doctors of the church is very small; and, in the special case of Liguori, he is not only the latest so named, but the only post-medieval casuist who has yet been canonized. Accordingly, it is not merely permissible, as heretofore, to follow his teaching, but it is now clothed with so high a degree of authority that it becomes matter of grave doubt

whether even such a modified expression of dissent from his teaching as occurs in the *Apologia* of Cardinal Newman in 1894 be now feasible without risk of censure. For the letters apostolic of Pius IX declare that the works of Liguori may be used publicly in the same manner as the writings of other doctors of the church, such as Augustine, Gregory the Great, and Thomas Aquinas, with, however, this notable difference that, whereas the teaching of those earlier doctors is necessarily qualified and conditioned by the subsequent development of theology, and by the successive glosses which they have received, on the other hand, Liguori's recent date makes him the sole authoritative interpreter of all moral theologians earlier than himself, while no writer has yet appeared to modify authoritatively, much less to supersede, his own moral teaching.

It may seem, at first sight, that a great advantage is gained by having thus a standard text-book on morals, even if some exceptions may be taken to its rulings in certain cases, because it may be expected to check serious divergency of opinion, and to put, indirectly at least, a high ethical ideal before the body of religious teachers. This, however, can be the case only when such a text-book expressly repudiates the principle of probabilism, and so comes to be ranked amongst rigorist works. For once probabilism is conceded as part of the system, as is the case with Liguori, then every opinion not officially condemned by authority, which is set down in the text-book itself, and is fortified with the names of any casuists of repute, becomes thereby probable and sanctioned, even though it be not the one professed by Liguori himself. Thus it may freely be followed by any priest in the confessional; and, what is yet more startling, it is the common and preferable doctrine that a penitent in confession can require absolution to be given him as a right, if he claim to have followed a probable opinion as to the act involved, even though not only the opposite opinion may be the more probable in the confessor's judgment, but that of the penitent seem absolutely false, and the confessor is therefore bound *sub gravi* to absolve in such a case (*Lig. Theol. Mor.*, v. 605); nor is it necessary that the opinion which the penitent advances should really convince or satisfy his own conscience. It is enough that it stands in the books, and is citable. Accordingly, the only practical effect of such a text-book as Liguori's is to undermine all rigorist propositions, and to make tenable every lax proposition, except the very few which have been specifically condemned.

As regards Liguori himself, his usual method is to begin with taking very high ground, and to state in unexceptionable terms the moral obligation of the precept with which he is concerned, but then to evacuate it of all real force by exceptions and qualifications. That such was felt to be the case, even in the relaxed society of his own day, appears from the frequency with which, even before his death, his moral teaching was impugned in Italy and France as of dangerous consequences, and from the number of apologies he was obliged to put forward in its defence.

He lays down broad general propositions, such, for example, as that all voluntary departure from the divine rule, whether of human and natural law or of revealed law, is sin (*Theol. Mor.*, ii. 1, 1); that nearly all sins against the decalogue are mortal sin (*Ibid.*, ii. 52, 2); that all sins, whether mortal or venial, deserve punishment (*Ibid.*, ii. 51, 1, 2); and, specifically, that all lying and falsehood is a breach of one precept of the decalogue (*Ibid.*, vi. 1, *proem*), and all theft and dishonesty a breach of another (*Ibid.*, iv. 518); but the favourable impression which such unimpeachable rulings produce is not maintained on further inquiry.

In the first place, he lays down that, to make any act sinful, three conditions must be fulfilled:—(1) it must be

done with consent of the will; (2) it must be free, that is, it must be in the power of the will to do it or leave it undone; (3) there must be intellectual consciousness (*advertentia*) of its evil nature. These look specious enough, and against the first no objection can be raised. But Liguori then alleges that violent gusts of passion or desire, which disturb the reason, and take away liberty of action, sometimes excuse from sin (*Ibid.*, ii. 1, 2). He is not speaking of actual insanity, which is not under consideration, and he adds that evil acts done by a drunken person are either not sinful at all, or are at most venial sins (*Ibid.*, ii. 1, 4), because the effect cannot be more sinful than the cause. And as to the degree of advertence necessary as a condition of sin, he first mentions the stricter view, that actual and immediate attention to the nature of the act is not required, but that a virtual knowledge of its character suffices, by which a man might reasonably be expected to recognize it, since otherwise all evil-doers who are blinded by their passions, or by a long course of malpractices, may go on taking no notice, and continue to commit sins with moral impunity. He then states the laxer and commoner view, that some direct advertence of the sinful nature of the act is necessary to constitute sin in doing it, and proceeds to reconcile these two opinions by ruling that voluntary ignorance, whether due to conscious neglect, to deliberate following of passion, to a course of evil habit, or to omission of the degree of consideration which the act demands, does not excuse from sin; but that all other forms of it do acquit the offender. The obscurity inseparable from some of these qualifications complicates a sufficiently simple matter, and in any case the doubter is at liberty to fall back on the laxer opinion. But there is one exception;—unbelievers and heretics cannot plead ignorance as their excuse. All their errors, of whatever kind, are imputed to them as sin (*Ibid.*, ii. 1, 4). A further difficulty is created by the distinction made between mortal and venial sins, and by the inferences drawn from this distinction. "A mortal sin is that which, by reason of its gravity, dissolves grace and friendship with God, and merits eternal punishment. It is called mortal, because it takes away the principle of spiritual life, that is, habitual grace, and brings death on the soul. A venial sin is that which, by reason of its slightness, does not take away grace and friendship, though it abates the warmth of charity, and deserves temporal punishment. It is called venial, because, without damage to the principle of spiritual life, that is, grace, it brings on the soul an easily curable weakness, and easily obtains pardon" (*Ibid.*, ii. 51). This seems at first merely a recognition of the broad practical distinction between serious and trifling offences acknowledged by every sound ethical thinker and by every civilized penal code. But its consequences go much further, for in the Roman system of casuistry the aim is as a rule to attenuate mortal sins into venial ones; while these latter are regarded as of such little moment as scarcely to deserve the very name of sin. This appears from the fact that, whereas the canon (xxi.) *Omne utriusque sexus fidelis* of the council of Lateran (1515), which first made private confession compulsory, enjoins the confession of all one's sins at least yearly, on the other hand, the council of Trent (Sess. xiv. c. 5) lays down that only mortal sins need be so disclosed, while venial sins, though they may be named in confession, according to the practice of devout persons, can be passed over in silence without any fault. And Liguori gives his own sanction to the proposition that a Christian does not sin gravely who proposes to commit *every one* of the venial sins (*Theol. Mor.*, v. 1, 12). Such being the light estimate of these sins, it might be fairly supposed that great care would be taken to mark them off so clearly from mortal sins that even the least instructed conscience could not

confuse them with each other. But every sin which, considered in itself, is mortal, becomes venial if any one of these three conditions be absent—full advertence and deliberation; entire consent; for the most part, gravity of the subject matter. Insufficient deliberation may be known in three ways.—imperfect consciousness of the sinfulness of the act, as if one were half asleep, subsequent regret, and a conviction that you would not have done the act had you fully apprehended it, such disturbance, through passion, alarm, or distraction, as to confuse the sense of what you were doing. Imperfect consent is established by the presence of a doubt in any one's mind whether he did really consent; by the habitual disposition being that of regarding mortal sin as a worse evil than death; by consciousness of having proceeded very timidly and hesitatingly in the action, by being half asleep, so as to be only doubtfully conscious, and being of opinion that the act would not have been done in case of full possession of the senses. And gravity of the subject matter is to be decided, not merely on the merits of the thing in itself, but in its relation to the end proposed by the agent. If it make but little for this end, it is trifling; if much, then it becomes serious (*Theol. Mor.*, ii. 54, 55, 56).

It is obvious that each of these subdivided qualifications admits of indefinite hair-splitting, and so that the security apparently provided by the general distinction between mortal and venial sins is elusive. It is true that there are also causes which will raise a venial sin to the rank of mortal, but the ascending process is more uncertain and difficult than the descending one. A venial sin, committed deliberately as a stepping-stone to a mortal sin, is to be judged in respect of this its object, and so becomes mortal. A venial sin, so passionately clung to as to make its votary ready to commit a mortal sin rather than forego its indulgence, also becomes mortal. But in neither of these cases is it necessary to confess the venial sin, only the mortal sin to which it has led up. The third mode of a venial sin becoming mortal is when it is committed with the formal and express purpose of disobedience to a superior, or to a precept, just because it is a precept. And in this case alone, because of the supreme place given to obedience in the Roman system, wherein it is not only the first and highest of virtues, but practically almost the only one insisted on for all, there is no manner of withdrawal from the category of mortal sins (*Theol. Mor.*, ii. 59, 60, 61).

So far, only the general principles on which Liguori's system is based have been explained. It next remains to exhibit their practical application, both as regards his own statements and also as regards the opinions of other casuists which, though not accepted by himself, he yet embodies without censure in his work, thereby giving them the character and sanction of probability. It will simplify the inquiry to limit it mainly, though not exclusively, to the teaching on falsehood and theft.

Both of these are declared by Liguori to be sins of grave character, and in regard to the former he cites, amongst other authoritative condemnations, these words of Pope Innocent III: "Not even to defend our life is it lawful to speak falsely." He adds that persons who are being lawfully questioned by such as have a right to interrogate, as judges in court, or a priest in the confessional, are bound to disclose truly all that they know of the matter inquired into. Those who are questioned by such as have no right to interrogate them, or are questioned irregularly by lawful authority, are not bound to communicate their knowledge, and may set aside and avoid such questioning by any lawful means—such means however, not including falsehood, nor answers made with mental reservation, making the words actually spoken false, this latter mode of evasion having been formally condemned by Innocent XI. in 1679, though it was permitted by the casuists of the immediately preceding period. This is all tenable enough, but its apparent force is only reduced by a little argument.

In the first place, he distinguishes amphibology or equivocation from mental reservation, and names three varieties of equivocation: (1) that of a word having two quite different senses, as *elo* in Latin means to "visit" and to "fly,"—to which may be added the frequent English ambiguity of two distinct words having the same sound, as *air* and *heir*, (2) a sentence having two main meanings, as "This

book is Peter's," which may signify his ownership or his authorship, (3) that of words having two senses, one more common than the other, or one literal and the other metaphorical. The example he gives of this last form is the phrase "I say No," uttered by a person who wishes to conceal something as to which he is questioned. The words seem to his hearer to denote express denial of the fact, the meaning in which he uses them is merely "I utter the word 'No,'" this sentence being complete in itself. "It is certain," adds Liguori, "and the common opinion of all, that it is lawful for a just cause to use equivocation in the manners described, and to confine it with an oath." And the reason is because we do not thus deceive our neighbour, but for a just cause permit him to deceive himself, and, besides, we are not bound, if there be a just cause, to speak so that others may understand. And any honest object for retaining any good things that are useful to our body or spirit may be a just cause" (*Theol. Mor.*, iv. 151).

But suppose that it is impossible to allege a just cause, is it then mortal sin to swear with such equivocation? Some of the stricter casuists say so, but Liguori sides with the laxists, and declares it merely venial, except in a court of law or in formal contracts,—alleging that, save in these two cases, any reasonable cause, such as desire to be quit of troublesome and irregular questioning, is sufficient to mitigate the sin. He adds, however, two cautions,—that a more serious cause is required to justify equivocation with an oath than without one, and that, in proportion as the equivocal words employed give greater occasion for mistake, a graver cause is required for their proper use, a qualification instantly modified by the next clause, which lays down that, when words which are in themselves equivocal, having two equally valid meanings, are used, then they give little or no cause for error, and may be used on the very lightest grounds.

Next, as to mental reservation, or "restriction," which is the technical name that was expressly condemned in three propositions by Innocent XI., forbidding it in all cases. According to the analogy of all prohibitory laws, this general prohibition of the genus should include prohibition of all the species also. But the casuists, unable to oppose direct resistance to the papal decree, have turned its flank by averring that the prohibition is unknown in 1679. They have not availed mental restriction into two main heads, the first of which, absolute or "pure" mental restriction (by which is meant such reservation as cannot possibly be observed by the hearer, or conjectured from the attendant circumstances), is always illicit, whether with or without an oath. But "non-pure" mental restriction, which is such as may possibly be observed and inferred from attending circumstances, such as an inaudible whisper, or a qualifying gesture) does not, they allege, fall under the ban of Innocent XI., and is always lawful for a just cause. The reason of this opinion is that, if it were not permissible to use non-pure mental restriction, there would be no manner of concealing a secret, which one could not disclose without loss or inconvenience, which would be as hurtful as lying to human intercourse. And therefore the condemnation passed by the pope on mental restriction is rightly to be understood of a restriction taken absolutely and strictly, for that alone can be called true mental restriction which takes place in the mind alone, and so remains hidden, and can in no way be recognized from external circumstances" (*Theol. Mor.*, iv. 152). And the following illustrations are supplied. (1) A confessor may affirm with an oath that he is ignorant of a crime which he has heard in confession, secretly meaning thereby that he is ignorant of it as a mere man, though not as a minister of religion. (2) An accused or a witness, if irregularly questioned by the judge in court, may swear that he knows nothing of a crime which he does in fact know of, understanding thereby that he does not know it so as to be legally bound to answer or depose concerning it. Thus when the interrogation of the judge is in, and the answer is lawfully questioned is bound to obedience, and barred from all equivocation. But this safeguard is at once fatally weakened by the further provisions that, if the act be not a crime in the witness's opinion, he need not disclose it, and that if the crime be altogether hidden (4), where only the criminal himself and the witness know the facts, the witness is not merely permitted, he is actually bound, to say that the accused did not commit it. And the accused is equally free to do so, unless there be already "half-full" proof against him, because, in the absence of such a degree of presumption, the judge has no legitimate right to question him as to his guilt. Those who have deceived the court by such sworn equivocation are, Liguori rules, entitled to absolution without the declaration of the truth being imposed as a condition. (3) A needy man, who has made

¹ I find in this teaching is the maxim laid down in another place, that it is lawful to procure the giving of perjury, provided "it be for a great interest in employing perjury to expose the fraud of another person in order to obtain your own rights" (*Theol. Mor.*, iii. 8, 77), with which may be coupled the permission for satutors to offer and for judges to take bribes for expediting causes, so long as the bribing is not expressly for delivering false judgment (*Ibid.*, v. 190, 212).

away, for his maintenance, with property due to his creditors, may affirm to the judge that he has nothing (4) A witness asked by the judge whether he has had any conversation with the accused may deny it, meaning that he has not talked with him so as to co-operate in the crime. (5) An adulterer, questioned by her husband as to her guilt, may deny it in any of these four ways. (a) that she has not broken the marriage-to, because it is not voided by adultery; (b) if she have gone to confession, she may say that she is innocent of the crime, because it has been remitted in confession; (c) that she has not committed adultery, using the word in its frequent Biblical sense of "violence"; (d) that she has not committed it so as to be bound to tell him of it (*Theol. Mor.*, iv. 163-162).

Promises are no safer than omissions under this code. As usual with Liguori, a broad statement of their binding character is prefixed to the qualifications which leave nothing but the outer shell remaining. For we are told (a) that "the whole obligation is commonly understood as depending on the intentions of the promisor, and not binding unless that be confirmed with an oath or a formal document, in the absence of which it may be considered a mistake or a jest"; and (b) that "it is certain that every promise, even an accepted one, does not bind, if after the date of the promise it becomes impossible, or very hurtful, or unlawful, or useless, and, generally speaking, when there has been a serious change of circumstances, which, if foreseen, would have prevented the promise, such a promise is always presumed to have been made under some such tacit condition" (*Theol. Mor.*, iv. 720).

Theft is treated in a very similar fashion. A broad general rule is laid down as to its sinfulness, and this is at once traversed by the following doctrine: "It is certain that a man who in an extreme necessity may pilfer other people's goods, especially to relieve himself from such necessity. So the doctors in common say, agreeing with St. Thomas." Extreme necessity is defined as meaning lack of loss of life, or of some limb or other important bodily member, peril of perpetual captivity, or of any serious disease or discredit. And Liguori, contradicting the stricter casuists, includes under the same heading the case of a man of rank ashamed to work or to beg, who then lawfully steal to maintain himself. Then the case is put whether a poor man in extreme need is free to steal before asking. One ignorant lays down that it is a mortal sin to do so, because no man can be held to be in an extreme necessity who can get what he wants by asking. But the laxer casuists rule that, though he is bound to ask first, he sins only venially by omitting to do so; and Ignatius takes it upon himself by saying that the robber sins mortally if he takes it not absolutely necessary to relieve his want, but that, if he does so need it that the owner, if aware of the fact, would be bound by the laws of charity to give it him, then he does not sin even venially by stealing it, because he has in that case an absolute right (*Theol. Mor.*, iv. 580).

Some of these rulings are convolved so as to evade the condemnation passed by Innocent XI. on the proposition that "it is allowable to steal, not only in extreme necessity, but also in grave necessity." But a more direct conflict with the papal ruling appears in respect of another censured proposition, that "men and women servants may secretly pilfer from their employers to compensate themselves for their work, which they account as of more value than the wages they receive." This is explicit enough, but it is set once and for all by the casuists, who allege that the rule holds good only in the case of a servant who has of his free will contracted to accept a low salary, as he thereby binds himself from compensation, but if he has made the bargain under any sort of constraint, as, for instance, being in great poverty, and thus glad to take any situation, he is at liberty to steal to the amount of what he considers his just additional wages. Some casuists do, indeed, question the servant's right to be judge and assessor in his own cause, but the point is ruled practically in his favour (*Theol. Mor.*, iv. 523-524). Again, casuists may pilfer such eatables and drinkables as are not locked up, provided they do so for their own consumption, and not to sell out of doors, and so long as each such theft is singly trifling (*Ibid.*, iv. 54). Even when restitution is enjoined, there is a notable provision in favour of the thief, who is to ascertain who it is he has robbed, he is to make restitution in one or other of certain ways, one of which is that if he be poor he may apply the proceeds of the theft to himself or to his family (*Prax. Confess.*, ii. 44).

In addition to these glosses on the decalogue, there is one element of doubtfulness introduced into nearly all questions of theft, which is, as to the "gravity of matter" constituting the offence mortal or venial according to the degree of this factor, and a comparison of the various places where Liguori employs the term "gravitas materiae" shows that in all cases where numerical expression can apply he means *quantity*. Accordingly, he is in common with many other casuists, concerned with the degree of guilt, depending, as a rule, on the amount stolen (*Theol. Mor.*, iv. 523-528).

A few brief citations from other decisions will show that the same principles applied to questions of lying and theft extend to the remaining forms of sin. (1) A man of high position may lawfully kill any one who attempts to slap his face, if there be no other way of warding off the insult (*Theol. Mor.*, iv. 85). (2) He who kills

A, meaning to kill B, is not bound to make compensation, because the homicide is casual and inadvertent as regards A; and similarly if a man burns down the house of his friend, meaning to burn that of an enemy (*Ibid.*, iv. 628, 626). (3) Though we are bound to love our enemies, we are not bound to salute them, to speak to them, to restrain them, to comfort them in any trouble, to receive them into our house, or to hold any kind of familiar intercourse with them (*Ibid.*, v. 3, 28). (4) A servant may help his master, by lifting him on his shoulders, or by providing him with a ladder, to enter a house, even forcibly, for immoral purposes, for the act is innocent and colourless in itself, may even an act of charity or good-will, and the servant is not responsible for the subsequent conduct of his employer (*Ibid.*, iii. 8, 6).

For all practical purposes, the probabilism which is at the base of all this casuistical method, and which is simply the substitution of an external authority for the dictates of conscience, is now in absolute possession throughout the Latin obedience, having finally conquered the resistance it has encountered at intervals since its first formulation as a working theory. Although it owes its chief development to the Jesuits, yet some of its ablest opponents were members of that company, such as Comitolus, Rebellus, Gubert, and even some of the generals, Mario Vicioli and Trino Gonzalez; while the Solonians and the Dominicans were also engaged in the controversy against its upholders, and in censuring the teaching of several of Liguori's favourite authorities, such as Lessius, Escobar, Tamburini, Baumy, Viva, Busembeur, and Diana.

LIGURIA, in ancient geography, was the name given to a portion of the north-west of Italy, including the districts, on both sides of the Maritime Alps and the Apennines, which border on the Tyrrhenian Sea from the frontiers of Gaul to those of Etruria. Along the sea-coast it extended from the river Varus or Var, which separated it from Gaul, to the Mactra (Magna), which formed its limit on the side of Etruria, thus comprising the whole district between the mountains and the sea, now known as the Riviera of Genoa. But besides this it comprehended a broad tract to the north of the same range, formed by the underfalls of the Apennines and the hilly tract adjoining them, extending to the plains of the Padus or Po,—that river itself constituting its northern limit under the Roman administration. But at an earlier period the term had a much wider significance,—all the tribes on the south slopes of the Alps, in the north-west of Italy, being apparently of Ligurian origin. This we are expressly told by ancient authors in the case of the Taurini, who dwelt around Turin, and of the Levi and Libici, who extended from thence to the Ticinus; and there can be little doubt that it was true also of the Salassi, who occupied the modern Val d'Aosta. But to the west of the Maritime Alps also the Ligurians were undoubtedly widely spread in ancient times, and occupied a considerable extent of what was afterwards included in Gaul. Thus the Salysae, who held all the southern part of Provence from the Var to the Rhone, are distinctly termed a Ligurian tribe, as well as the minor tribes of the Oxybii and Deciates, near Frejus and Nice. All the early Greek writers speak of the important colony of Massilia as founded in Liguria.

Of the origin or affinities of the Ligurians (or Lygians, as they are termed by Greek writers) we know absolutely nothing. All ancient writers concur in representing them as a distinct people from the Gauls on the one hand, and from the Iberians on the other; and the attempts of some modern writers to assign them to a Celtic stock rest upon no adequate foundation. In the absence of all remains of their language, all such speculations must be matters of mere conjecture. They appear in the historical period as a rough and hardy race of mountaineers, cultivating a

rugged territory with much industry, and opposing a stubborn resistance to the efforts of the Romans to reduce them to subjection. They first came in contact with the Roman arms in 235 B.C., but it was not till after the Second Punic War—in which the Ligurians had openly opposed the cause of Hannibal—that a serious struggle began, which, commencing in 200 B.C., was continued with little intermission for more than eighty years. While the Roman generals in the East were overthrowing, with comparative ease, the powerful monarchies of Macedonia and Syria, one of the consuls was generally engaged in inglorious hostilities with the hardy mountaineers of the Ligurian Apennines. Even after these were reduced to subjection, the tribes which held the still more rugged fastnesses of the Maritime Alps long maintained their independence, and it was not till the reign of Augustus that they were finally subdued. The construction by that monarch of a Roman highway along the coast, which followed almost exactly the same line as the modern road of the Corniche, marked the period of their complete subjection.

The physical geography of Liguria has been already described in the article of ITALY. All the rivers which take their rise on the northern slope of the mountains ultimately discharge their waters into the Po; of these by far the most considerable is the Tanaro, which receives the tributary streams of the Stura and the Bormida, while to the east of it flow the Scrivia and the Trebia, celebrated by the victory of Hannibal over the Romans. This last stream, according to the division of Augustus, formed the boundary between Liguria and Gaul south of the Po. The streams which flow from the Apennines southward to the sea are for the most part inconsiderable, and mere mountain torrents. But the Magra, which forms the limits of the province on the east, is an important stream, and brings with it the waters of its tributary, the Boates or Vara. On the west also the Var is a river of considerable magnitude, which forms a natural boundary on this side between Liguria and Gaul, as it long constituted their political limit. The Rattuba or Roya, a little farther east, is also a considerable river, descending through a deep mountain valley from the Col di Tenda.

The principal Ligurian tribes were (1) the Apuani, inhabiting the valley of the Magra, including the district known in modern times as the Lunigiana; (2) the Friniates, on the northern slope of the Apennines towards Modena; (3) the Briniates, in the valley of the Vara; (4) the Gennates, around Genoa; (5) the Veturi, immediately west of the preceding; (6) the Ingauni, whose capital was Albium Ingaunum, still called Albenga; (7) the Intemelii, whose chief city still retains the name of Vintimiglia; and (8) the Vediauti, extending thence to the Var. North of the Apennines the most important tribes were the Vagienni, who held the whole mountain tract from the Monte Viso and the sources of the Po to the Tanaro; and the Statielli, east of them, whose chief town was Aquæ Statiellæ or Aouë.

The chief city on the Ligurian sea-coast was, in ancient as in modern times, that of Genoa, which combined an excellent natural port with a central position, and easy communications with the interior. West of it, along the coast, were Vada Sabotta (Vado, near Savona), Albium Ingaunum (Albenga), Albium Intemelium (Vintimiglia), the Portus Herculis Monacensis (Monaco), and Nicaea (Nice), which was founded by a colony from Massilia. In its immediate vicinity was the Roman town of Camenellum (Cimiez). On the northern slope of the Apennines were several considerable towns, almost all of them of Roman origin. The chief of these were Augusta Vagiennorum (Bene), Alba Pompeia, Asta, Aquæ Statiellæ, Derconia (Torlona), and Iris (Voghera), but none of them attained

to anything like the same prosperity and importance as the great cities of Cisalpine Gaul. The towns on the eastern Riviera, between Genoa and the Gulf of Spezia, were inconsiderable places, and even on the shores of that gulf, forming the magnificent port called the Portus Lunæ, there was never any town of importance, Lunæ itself being some distance inland, and within the confines of Etruria. (S. U. A.)

LILAC, *Syringa vulgaris*, L., belongs to the olive family, *Oleaceæ*. The common lilac is said to have come from Persia in the 16th century, but according to Heuffel it is indigenous in Hungary, the borders of Moldavia, &c. (De Candolle, *Prod.*, viii p. 283). Two kinds of *Syringa*, viz., *alba* and *cærulea*, are figured and described in Gerard's *Herball* (1597), which he calls the white and the blue pipe privets. The former is the common privet, *Ligustrum vulgare*, L., which, and the ash tree, *Fraxinus excelsior*, L., are the only members of the family native in Great Britain. The latter is the lilac, as both figure and description agree accurately with it. It was carried by the European colonists to North-East America, and is still grown in gardens of the Northern and Middle States. There are several varieties of lilac, e.g., "Dr Lindley," which bears large clusters of reddish lilac flowers, *alba*, *violacea*, *rubra insignis*, and *rosea grandiflora*. *S. dubia*, Pers., or *chinensis*, Willd., the Siberian lilac, is a closely allied species, if it be really distinct. The variety *Rothomogensis*, Mirb., or *Lilac Farnæ* of the French, probably belongs to this species. Of other species, there is *S. Josikeæ*, Jack., from Transylvania, with scentless bluish-purple flowers, *S. Emodi*, Wall., a native of the mountains of India, and *S. persica*, L., the Persian lilac, rarely exceeding 4 or 5 feet, the flowers of which vary from rosy carmine to white.

LILBURNE, JOHN (1618-1657), an English sectary and prolific pamphleteer, was the younger son of a gentleman of good family in the county of Durham, and was born in 1618. At the age of twelve he was apprenticed to a clothier in London, but he appears to have paid only slight attention to business, and to have early addicted himself to the "contention, novelties, opposition of government, and violent and bitter expressions" for which he afterwards became so conspicuous as to provoke the saying of Marten that, "if the world was emptied of all but John Lilburn, Lilburn would quarrel with John, and John with Lilburn." He appears at one time to have been law-clerk to Prynne. In February 1638, for the part he had taken in importing and circulating the *Merry Leitanie* and other publications of Bastwick and Prynne, offensive to the bishops, he was sentenced to be publicly whipped from the Fleet prison to Palace Yard, Westminster, there to stand for two hours in the pillory, and afterwards to be kept in jail until a fine of £600 had been paid. Though gagged at the pillory, and confined in prison, he was not the man to give up his opinions or forego the pleasure of expressing them, and in the following year he did not improve his prospects of a speedy release by the kind of literary activity to which he devoted his enforced leisure.¹ In point of fact he did not regain his liberty until November 7, 1640, when one of the earliest recorded speeches of Oliver

¹ Come out of Her, My People: or An Answer to the Questions of a Gentleman, a professor in the Anti-Christian Church of England, about Hearing the public Ministers; where it is largely discussed, and proved to be unlawful. Also a Just Apology for the way of Total Separation, commonly but falsely called "Brownism"; that it is the truth of God though slightly esteemed in the eyes of the world. With a challenge to dispute them publicly before King and Council, to prove whatsoever I have said at the pillory against them: viz., that the calling of them is Jure Diaboli, even from the Devil himself. By John Lilburne, close prisoner in the Fleet for the cause of Christ. Printed in the year of hope of England's Purgation and the Prelates' Dissolution, 1639.

Cromwell was made in support of his petition to the House of Commons. In 1641 he received an indemnity of £3000. He now entered the army, and in 1643 was taken prisoner at Brentford and tried for his life, sentence would no doubt have been executed had not the parliament by threatening reprisals forced his exchange. He soon rose to the rank of lieutenant-colonel, but in April 1645, having become dissatisfied with the general conduct of affairs, and especially with the predominance of Presbyterianism, he resigned his commission, presenting at the same time to the Commons a petition for considerable arrears of pay. His violent language in Westminster Hall about the speaker and other public men led in the following July to his arrest and commitment to Newgate, whence he was discharged, however, without trial, by order of the House, in October. In January 1647 he was again committed to the Tower for accusations which he had brought against Cromwell, but was again set at liberty in time to become a disappointed spectator of the failure of the levelling or ultrademocratic party in the army at the Ware rendezvous in the following December. The scene produced a deep impression on his mind, and in February 1649 he along with other petitioners presented to the House of Commons a paper entitled *The Serious Apprehensions of a part of the People on behalf of the Commonwealth*, which he followed up with a pamphlet, *England's New Chains Discovered* (March 1, 1649), criticizing Ireton, and another exposing the conduct of Cromwell, Ireton, and other leaders of the army since June 1647. *The Hunting of the Foxes from Newmarket and Triploe Heath to Whitehall by Five Small Hengles*, the "beagles" being Lilburne, Overton, Walwyn, Prince, and another. Finally, the *Second Part of England's New Chains Discovered*, a violent outburst against "the dominion of a council of state, and a constitution of a new and unexperienced nature," became the subject of discussion in the House, and led anew to the imprisonment of its author in the Tower on April 11. His trial in the following October, on a charge of seditious and scandalous practices against the state, resulted in his unanimous acquittal, followed by his release in November. In January 1652, for printing and publishing a petition against Sir Arthur Hasling and the Haberdashers' Hall for what he conceived to have been an injury done to his uncle George Lilburne in 1649, he was sentenced to pay fines amounting to £7000, and moreover to be banished the Commonwealth, with prohibition of return under the pain of death. In June 1653 he nevertheless came back from the Low Countries, where he had busied himself during the interval in pamphleteering and such other agitation as was possible, and was immediately arrested; the trial, which was protracted from July 13 to August 20, indeed issued in his acquittal, to the great joy of London, but it was nevertheless thought proper to keep him in captivity for "the peace of the nation." He was detained successively in the Tower, in a castle at Jersey, and in Dover Castle. At Dover he came under Quaker influence, and signified his readiness at last to be done with "carnal sword fightings and fleshly brawlings and contests", and in 1656, on giving security for his good behaviour, he was set free. He now settled at Eltham in Kent, frequently preaching at Quaker meetings in the place and neighbourhood during the brief remainder of his troubled life. He died on August 29, 1657.

See Masson, *Life of Milton*, who refers (iv 150) also to Walker (*History of Independency*, ii 247), Godwin (*Commonwealth*, iii 193-177), and Bisset (*Unsettled Chapters of the History of England*, 191-201), and adds, "Mr. Bisset relates Lilburne's trial (on 1649) at length, with curious extracts, and makes John more of a hero than Godwin does, though Godwin is not unfavorable. On the whole, I like him myself, and am glad that he is in the history of England, but think he was an ass."

LILLE, capital of the department of Nord, France, and the ancient capital of Flanders, is situated about 155 miles by rail north of Paris, and at an elevation of 75 feet, in a low plain on the Deule, which flows to the Scheldt by the Lys. It is the chief fortress of the north of France, and headquarters of the first army corps, and is defended by a rampart and by a pentagonal citadel situated to the west of the town beside the Deule. The water of the river fills the moat, and the environs of the citadel can be laid under water. Prior to 1858 the town occupied an elliptical area of about 2500 yards by 1300, with the church of Notre Dame de la Treille in the centre, but the ramparts on the

south side have since been demolished and the ditches filled up, their place being now occupied by the great Boulevard de la Liberté, which extends in a straight line from the goods station of the railway to the citadel. The new enceinte is much more extensive, and encloses the old communes of Esquermes, Wazemmes, and Moulins-Lille, the area of the town being thus more than doubled, in the new quarters fine boulevards and handsome squares, such as that of De la République, have been laid out in pleasant contrast with the sombre and dirty aspect of the old town. The district of St André to the north, the only elegant part of the old town, is the residence of the Lille aristocracy.

At the demolition of the old fortifications, the Paris gate, a triumphal arch erected in 1682 in honour of Louis XIV., after the conquest of Flanders, was preserved, as also the Ghent and Ronbaix gates, which date from the time of the Spanish domination, and are built in the Renaissance style, with bricks of different colours. The present rampart is pierced by eleven gates, besides a special gate for the railway, and two water gates for the canal of the Deule. The goods station has also its special outlet, and a line from it, after making the round of the new quarters, passes within the enceinte to the quays of the river. Crossing the bridges which span the different arms of the Deule, we reach the citadel, the glacis of which,

planted with trees, form a public walk. Within the citadel are extensive barracks and a considerable arsenal. The church of Notre Dame de la Traille, in the style of the 13th century, which has been in process of building since 1855, occupies the site of the old Château du Buc, the original nucleus of the city. The town-house, on the site of the old palace of the duke of Burgundy, Philip the Good, was built in 1846. The exchange, which dates from the period of the Spanish domination, is in an original style. It is surmounted by a graceful campanile, and contains a statue of Napoleon I., made from cannon taken at Austerlitz. In the middle of the great square stands a column, erected in 1848, commemorating the defence of the town in 1792. There are several large hospitals, faculties of medicine and of science, a Catholic institute, comprising the five faculties of theology, letters, law, science, and medicine, an academy of music affiliated to the Conservatoire at Paris, several learned societies, and a large number of various kinds of schools. The picture gallery, with upwards of eight hundred works, is one of the richest in the provinces, and the Wier museum contains a unique collection of original designs of the great Italian masters. Lille possesses also an ethnographical museum (Musée Moillet), as well as museums of archaeology, numismatics, the industrial arts, and natural history. The communal library is also worthy of mention; it includes numerous MSS., and particularly a valuable *Evangelicarium* of the 12th or 13th century. On the front of the building where the departmental archives are kept are to be seen medallions of all the sovereigns who have successively possessed Lille from Baldwin of the Iron Arm to Louis XIV. Lille, which is pre-eminently a manufacturing and commercial town, enjoys exceptional advantages as regards means of transit. The lower Deule is canalized to its junction with the Lys, and there is continuous water communication with the Scheldt in Belgium, and with Paris by way of Douai and St Quentin. The town is at the same time an important railway junction, and is also provided with tramways.

The principal industry is flax-spinning, in which thirty-five mills, with 190,000 spindles, give employment to 14,000 persons (of whom 9000 are females), the annual turnover being £1,800,000. Forty thread mills employ 2000 persons, and produce thread to the annual value of £240,000. Fifteen factories, with 1000 operatives, produce woollen goods worth from £120,000 to £160,000 per annum; 5000 persons are engaged in cotton-spinning (115,000 spindles), to the amount of £800,000. There are besides eighty factories in which damasks, tickings, and the usual staples of the linen trade are manufactured; quilts and pocketbags occupy from 6000 to 7000 persons, and 4000 are employed in producing the fabric out of which the smock frocks of the peasantry are made. Connected with these industries are dye-works, bleach-fields, and establishments for the production of engines, looms, and combing and carding machines; and there are also chemical works, sugar-works, breweries, and oil-works.¹ The state manufacture of tobacco in Lille gives employment to 1200 persons. The total population of Lille in 1876 was 162,775.

Lille is said to date its origin from the time of Count Baldwin IV., who in 1080 surrounded with walls a little town which had arisen around the castle of Buc. At the end of the 12th century Lille, which had developed rapidly, obtained communal privileges. Destroyed by Philip Augustus in 1212, it was rebuilt by John of Constantinople, but besieged and taken by Philip the Fair in 1297. After having taken part with the Flemings against the king of France, it was ceded to the latter in 1312. In 1869 Charles V. gave it to Louis de Male, who transmitted his rights to his daughter

Margaret, wife of Philip the Bold, duke of Burgundy. Under the Burgundian rule Lille enjoyed great prosperity, its merchants were at the head of the London fairs. Philip the Good made it his residence, and within its walls held the first chapters of the order of the Golden Fleece. With the rest of Flanders it passed from the dukes of Burgundy to Austria, and then to Spain. After the death of the Philip IV. of Spain, Louis XIV. reclaimed the territory, and besieged Lille in 1667. He forced it to capitulate, but preserved all its laws, customs, privileges, freedoms, and liberties. In 1708, after an heroic resistance, it surrendered to Prince Eugene and the duke of Marlborough. The treaty of Utrecht ceded it to France. In 1792 the Austrians bombarded it for nine days and nights without intermission, but had ultimately to raise the siege. (G. ME.)

LILLEBONNE, capital of a canton in the department of Seine-Inférieure, France, 131 miles west-north-west by rail from Paris, and 20 miles due east from Havre, is a pretty little town, picturesquely built at the foot of wooded hills, in the valley of the Bolbec, which falls into the Seine 3 miles lower, at Port Jérôme. The principal industries are cotton-spinning and the manufacture of calico. The population in 1876 was 5400.

Lillebonne was the capital of the Calvetae, or inhabitants of the Pays de Caux, in the time of Cæsar, by whom it was destroyed. It was afterwards rebuilt by Augustus, who called it Julibona after his daughter, and before it was again ruined by the barbarian invasions it had become a very important centre, whence Roman roads branched out in all directions. Some forty years ago the remains of a mosaic baths and of a theatre capable of containing 3000 persons were brought to light. Statues, tombstones, all sorts of articles in iron, bronze, ivory, marble, stone, glass, &c., have been found in the course of excavation, and deposited, for the most part, in the museum at Rouen. The most beautiful object yet discovered is a large mosaic found in 1870 (some 28 feet by 21). In the Middle Ages the fortifications of the town were constructed out of the materials supplied by the theatre. William of Normandy built at Lillebonne a castle whence he dates several charters. It is now a ruin within a charming park. The 18th century houses, with walls over 19 feet in thickness, is an admirable preservation. The church of Notre Dame, of the 16th century, had a fine porch, formerly adorned with rich sculptures, which have mostly disappeared. The graceful tower is about 180 feet high.

LILLY, WILLIAM (1602–1681), an astrologer somewhat famous in his day, was born in 1602, at Diseworth in Leicestershire, his family having been settled as yeomen in the place for “many ages.” He received a tolerably good classical education at the school of Ashby-de-la-Zouche, but he naively tells us what may perhaps have some significance in reference to his after career, that his master “never taught logic.” In his eighteenth year, in consequence of his father having fallen into great poverty, he went to London, and was employed in a sort of menial situation in attendance on an old citizen and his wife, with whom he so managed to ingratiate himself that his master, at his death in 1627, left him an annuity of £20; and, Lilly having soon afterwards married the widow, she, dying in 1633, left him property to the value of about £1000. Having now a good deal of leisure on his hands, he began to dabble in astrology, reading all the books on the subject he could fall in with, and occasionally trying his hand at unravelling mysteries by means of his art. The years 1643 and 1643 were devoted to a careful review of all his previous reading, and in particular having lighted on Valentine Nailod’s *Commentary on Alcabitus*, he “seriously studied him and found him to be the profoundest author he ever met with.” Him he “traversed over day and night,” and so “advanced his judgment and knowledge” to the utmost height he ever arrived at. He characterizes him as “a most rational author and the sharpest expositor of Ptolemy that hath yet appeared.” About the same time he tells us that he “did carefully take notice of every grand action betwixt king and parliament, and did first then incline to believe that as all sub-lunary affairs depend on superior causes, so there was a possibility of discovering them by the configurations of the superior bodies.” And, having thereupon “made some essays,” he “found encouragement to proceed further, and

¹ The old commune of Moulins, now annexed to the town, derived its name from the windmills in which the oil was pressed.

ultimately framed to himself that method which he ever afterwards followed." He then began to issue his prophetic almanacs and other works, and it is a curious illustration of the state of intelligence even among educated people at the time that trash of this kind really seems to have met with serious attention from some of the most prominent members of the Long Parliament. If we may believe himself, Lilly lived on friendly and almost intimate terms with Bulstrode Whitlocke, Lenthall the speaker, Sir Philip Stapleton, Elias Ashmole, and others. Even Selden seems to have given him some countenance, and probably the chief difference between him and the mass of the community at the time was that, while others believed in the general truth of astrology, he ventured to specify the future events to which its calculations pointed. Even from his own account of himself, however, it is evident that he did not trust implicitly to the indications given by the aspects of the heavens, but like more vulgar fortune-tellers kept his eye and ears open for any information which might make his predictions safe. It appears that he had correspondents both at home and in foreign parts to keep him conversant with the probable current of affairs. He was evidently a proficient in all the unscrupulous cunning, adroitness, and plausibility which go to make up the successful quack and impostor, and not a few of his exploits indicate rather the quality of a clever police detective than of a profound astrologer. After the Restoration he very quickly fell into disrepute. His sympathy with the parliament, which his predictions had generally shown, was not calculated to bring him into royal favour, and the frivolous and sceptical character of the age could scarcely be expected to fall in with transcendentalism either in the shape of sense or nonsense. He came under the lash of Butler, who, making allowance for some satiric exaggeration, has given in the character of Sildrophel a probably not very incorrect picture of the man; and, having by this time amassed a tolerable fortune, he bought a small estate at Hersham in Surrey, to which he retired, and where he diverted the exercise of his peculiar talents to the practice of medicine. He died in 1681, in the eightieth year of his age.

Lilly's life of himself, published after his death, is still worth looking into as a remarkable record of credulity and successful imposture. Superstition dies hard; and it is a curious evidence of the inveteracy of popular delusions that so lately as 1869 a prominent London publisher put forth a new edition of Lilly's *Introduction to Astrology*, "with numerous emendations adapted to the improved state of the science."

LILY, *Lilium*, the typical genus of *Liliaceae*, embraces nearly fifty species, all confined to the northern hemisphere, about fifteen being natives of Japan and China, six of the mountains of India, eight of south Europe, five of the east and nine of the west coasts of North America. The earliest in cultivation were described in 1597 by Gerard (*Herbal*, p. 146), who figures eight kinds of European (true) lilies, viz., *L. album*, *L. candidum*, L., and a variety, *L. biancolum*, two umbellate forms of the type *L. bulbiferum*, Park., named *L. aureum* and *L. cruentum latifolium*, and three with pendulous flowers, apparently forms of the martagon lily. Parkinson, in his *Paradiſus* (1629), described five varieties of martagon, six of umbellate kinds—two white ones, and *L. pomponium*, *L. chalcedonicum*, *L. corniculatum*, and *L. pyrenaicum*—together with one American, *L. canadense*, which had been introduced in 1629. For the ancient and medieval history of the lily, see M. de Cannart d'Harnale's *Monographie historique et littéraire des Lis* (Malines, 1870). Since that period many new species have been added. The latest authorities for description and classification of the genus are J. G. Baker ("Revision of the Genera and Species of Tulipæ," *Journal of Tenn. Soc.* xiv. p. 211. 1874) and J. H. Elwes

(*Monograph of the Genus Lilium*, 1877-78), who first tested all the species under cultivation, and has published every one beautifully figured by W. H. Fitch, and some hybrids. With respect to the production of these latter, the genus is remarkable for its power of resisting the influence of foreign pollen, for the seedlings of any species, when crossed, generally resemble that which bears them. For the harder kinds in cultivation, reference may be had to Hemsley's *Handbook of Hardy Trees*, &c., p. 601. The structure of a lily is of simple type, consisting of two whorls, of three free parts each, six free stamens, and a consolidated pistil of three carpels, ripening into a three-valved capsule containing many winged seeds. In form, the flower assumes three types:—trumpet-shaped, with a more or less elongated tube, e.g., *L. longiflorum* and *L. candidum*; an open form with spreading perianth leaves, e.g., *L. auratum*, or assuming a pendulous habit, with the lips strongly reflexed, e.g., the martagon type. All have scaly bulbs, which in three west American species, as *L. Humboldtii*, are remarkable for being somewhat intermediate between a bulb and a creeping rhizome. *L. bulbiferum* and its allies produce aerial reproductive bulbils in the axils of the leaves. The bulbs of several species are eaten, such as of *L. aviculatum* in Kamchatka, of *L. Martagon* by the Cossacks, and of *L. tigrinum*, the "tiger lily," in China and Japan. Medicinal uses were ascribed to the species, but none appear to have any marked properties in this respect. See **HORTICULTURE**, vol. xii. p. 257.

The white lily, *L. candidum*, the *lilyon* of the Greeks, was one of the commonest garden flowers of antiquity, appearing in the poets from Homer downwards side by side with the rose and the violet. According to Heins, roses and lilies entered Greece from the east by way of Phrygia, Thrace, and Macedonia (*Kulturpflanzen und Haustiern*, 3d ed., p. 217). The word *lilyon* itself, from which *lilium* is derived by assimilation of consonants, appears to be Roman (*Idia*, p. 827), and according to ancient etymologists (*Leviada*, *Idia*, p. 227) the term of Sans was connected with the Persian name of the lily *shian* (*Græcorum*, Heb. *shohan*). Mythologically the white lily, *Rosa Junonia*, was fabled to have sprung from the milk of Hera. As the plant of purity it was contrasted with the rose of Aphrodite. The word *epion*, on the other hand, included red and purple lilies. Plin. *H. N.*, xvi. 5 (11, 12), the red lily being best known in Syria and Judæa (Phœnias). This perhaps is the "red lily of Constantinople" of Gerard, *L. chalcedonicum*, L. The lily of the Old Testament (*shohan*) may be conjectured to be a red lily from the simile in Cant. v. 18, unless the allusion is to the fragrance rather than the colour of the lily, in which case the white lily must be thought of. The "lilies of the field," Matt. vi. 28, are *epion*, and the comparison of their beauty with royal robes suggests their identification with the red Syrian lily of Phrygia. Lilies, however, are not a conspicuous feature in the flora of Palestine, and the red Galilee are dotted in the spring, is perhaps more likely to have suggested the figure. For the lily in the pharmacopœia of the ancients see Adams's *Paul. Ægineta*, lib. 106. It was used in unguents and against the bites of snakes, &c. In the Middle Ages the flower continued to be common, and was taken as the symbol of heavenly purity. The three golden lilies of France are said to have been originally three leaves-buds.

LILYE, WILLIAM (c. 1436-1523), one of the introducers of a knowledge of the Greek language into England, was born at Odham, in or about the year 1466. He entered the university of Oxford in 1484, became a demy of Magdalen in 1486, and after taking his first degree in arts went on a pilgrimage to Jerusalem. On his return he put in at Rhodes, which was still occupied by the Knights, under whose protection many Greeks had taken refuge after the taking of Constantinople by the Turks. Here he laid the foundation of a knowledge of the Greek language. We next hear of him in Italy, following the lectures of John Sulphitius and Pomponius Letus at Rome. From this he passed on to Venice, from which place he writes to his friend and patron Thomas Starkey, that "he is assiduously attending the lectures of Egnatius in Latin, but that he finds no one in Venice who can assist him in the study of Greek. He reads, however, Greek by himself, and has

read seven plays of Sophocles, five of Euripides, three of Aristophanes, besides extracts from Xenophon and Plutarch, by himself without a teacher." After his return he settled in London, as a private teacher of grammar, and is believed to have been the first who taught Greek in that city. In 1510 Colet, dean of St Paul's, who was then founding the school which afterwards became famous, appointed Lilye the first highmaster. He held this office only twelve years, dying of the plague in February 1523.

Lilye's name deserves commemoration, not only as one of the pioneers of Greek learning, but as one of the joint authors of a book, familiar to many generations of students, down to the present century, the old Eton Latin grammar. The *Discretissima Institutio*, a sketch by Colet, corrected by Erasmus, and worked upon by Lilye, contains two portions, the authorship of which is indisputably Lilye's. These are the lines on the genders of nouns, beginning "Propria que maribus," and those on the conjugation of verbs, beginning "As in presenti." The "Carmen de moribus" bears Lilye's name in the early editions, but Hearne asserts that it was written by Leland, who was one of his scholars, and that Lilye only adopted it. Besides the *Discretissima Institutio*, Lilye wrote a variety of Latin pieces both in prose and verse. Some of the latter are printed along with the Latin verses of Sir Thomas More in *Progymnasmata Thomae Mori et Gulielmi Lylii Sodalium*, Basel, 1518. Another volume of Latin verse directed against a rival schoolmaster and grammarian, Whittington, whose grammar that of Lilye superseded, is entitled *Antibosscon ad Gulielmum Hovmannum*, 1521.

The only authority for the few facts which make up the above life of Lilye is a short sketch furnished by his son George to Paulus Jovius who was collecting for his history the lives of the learned men of Great Britain. All the other names, such as Paley, Pitt, Fuller, Wood, which figure in the dictionaries as authorities, are only transcripts of George Lilye. To these scanty memoranda the present article adds an extract from three letters of Lilye's preserved in the British Museum, Cotton Nero, B vi. fol. 167, now printed for the first time.

LIMA, capital of the republic of Peru, as also of the department and province of Lima, is situated on an extensive plain, 500 feet above the sea-level, and 7 miles east from its port Callao on the Pacific coast, in $12^{\circ} 2' 34''$ S lat., $77^{\circ} 7' 36''$ W. long. The general configuration of the main portion of the city, previous to 1870 surrounded by walls, is that of an irregular triangle, whose base rests on

FIG. 1.—Neighbourhood of Lima and Callao

the river Rimac, which separates the city from its offshoot or suburb of San Lazaro. Sheltered on the north and east by the spurs of the Andes, the city is exposed to the winds prevailing from the south-east, as also to those from the south and west. Although the atmosphere is moist, and the transitions of the seasons are rapid, the climate is not unhealthy, the rainfall being slight, and the variations of

temperature not excessive. The summer commences in December, and the winter in June, and the mean temperature for the year is about 73° Fahr. The city is divided into five quarters or parishes, and is well laid out with broad and regular thoroughfares, the streets intersecting one another at right angles. The houses are spacious, but generally of only two stories, and are approached by portal leading into an open court or yard. In the principal square, which covers an area of 9 English acres in the centre of the city, stands a fine fountain of bronze. Here also are the cathedral, a stone structure with two lofty towers and a broad façade, the archiepiscopal palace, the Government house, and the Portal de los Escribanos, containing the municipal offices and archives. Besides the cathedral there are five chief parochial and sixty-two other churches and chapels, and numerous monasteries and convents. Of the churches, the largest is that of San Pedro (1598), which has seventeen altars, of the religious houses that of the Dominicans is the finest, and that of the Franciscans the most extensive. The university, built in 1576, is the oldest in America, it contains the hall and offices

used by the chamber of deputies. Lima has more than seventy schools, a public library containing upwards of forty thousand volumes, and many charitable institutions, several of them connected with the religious orders. The principal place of amusement is the amphitheatre for bull-fights in the Plaza del Acho, accommodating nine thousand spectators. In the Plaza de la Exposición is a marble statue of Columbus unveiling a figure of America. Of the many other monuments in Lima the most famous is the bronze equestrian statue of Simon Bolivar in the Plaza de la Independencia (or de Bolívar), 11 tons in weight, commemorating the battle of Ayacucho, which secured the independence of Peru. Among the public promenades are reckoned the cemetery outside the Marvillas gate, and the Paseo de la Alameda de los Descalzos, in the centre of which is a gorgeous garden. As the capital of Peru, Lima is one of the most important trading centres in South America. It has, however, but few home industries, its manufactured goods being chiefly imported from Europe via Callao, the medium of nearly all its foreign commerce. Several attempts have from time to time been made to establish factories, but the high

price of labour has hitherto prevented any efforts on a large scale being permanently successful. There are, however, manufacturers for tallow, soap, sperm candles, glue, gold lace, gut leather, and silver filigree works, and the capital supplies the towns of the republic with coarse woollen fabrics. The market is attended daily by about a thousand dealers. Fish is supplied from Callao, and vegetables partly from gardens in the city and environs, and partly from the native villages. Since 1857 the water for drinking purposes has been obtained filtered from the Rimac, and supplied by pipes to the houses. The imports are various; the exports include guano, cinchona, Indian wool, raw cotton, hides, sugar, saltpetre, gold, silver, and other minerals. Under ordinary conditions the imports and exports together exceed \$5,000,000 annually. There are railways from Lima leading to Callao, Chancay, Chorrillos, and Oroya; the construction of several other lines has been stopped by the war with Chili. In 1780 the population of Lima was 50,000; in 1860 it had reached 100,341, and in 1868 121,363, of whom 38,761 were foreigners. A recent estimate (1877) gives the number at about 200,000, but, considering the vicissitudes the city has since then endured, these figures must be considered at the present time (1882) as far too high. The Spanish natives have the reputation of being courteous, affable, and generous, but at the same time fond of pleasure, improvident, and superstitious. By confession they are mostly Roman Catholics.

Lima was founded 161 January 1535, by Francisco Pizarro, who named it *Ciudad de los Reyes* in honor of the emperor Charles V. and Don Juan his mother, or, according to some authors, from its site having been selected on the 8th January, the Feast of the Epiphany. The name afterwards gave place to that of *Lima*, a Spanish corruption of the Quichua word *Rimac*. In 1548 Lima received its first archbishop, and in 1552 the earliest provincial council for the state was held there. Remaining under Spanish rule during the 17th, 18th, and early part of the 19th centuries, the city continued to increase in prosperity, though often visited by terrible earthquakes, of which the most disastrous was that of the 28th October 1746, when 5000 of the inhabitants perished and the port of Callao was destroyed (see CALLAO, vol. xv. p. 107). On the 12th July 1821, after a short siege, Lima was entered by a Chilean force under General San Martín, who on the 28th was proclaimed protector of Peru as a free state, but its independence was not finally secured until after the victory of Ayacucho (9th December 1824). In March 1828 the city again suffered from an earthquake, and in 1854-55 the yellow fever carried off a great number of the inhabitants. On the 11th of August 1867, Mr Sullivan, British minister to Peru, was assassinated. In November 1868 a congress of plenipotentiaries from Chili and other South American states was held here to concert measures of mutual defence. Of the various revolts which have during the last few years taken place at Lima may be mentioned that of November 1866, when President Pizarro was displaced for Canseco; the riots against religious toleration, 15th April 1867, and the military insurrection, 22d July 1873, when Gutierrez, minister of war, arbitrarily assumed power, had President Belzu imprisoned, and shot, but himself soon fell a victim to the popular fury, order being afterwards with difficulty restored by Vice-President Zavala. In consequence of the ill-success of the war with Chili, Lima towards the close of 1879 was again in an unsettled condition; President Prado fled, and on the 22d December, after a sanguinary coup d'état, Pierola was proclaimed dictator. In April 1880 Callao was blockaded by Chilean war ships, and Lima had to be placed in a state of defence. On the 20th of November the Chilean army effected a landing at Pisco, a fortified place about 100 miles south of Lima, and, having afterwards advanced upon the capital, forcibly occupied it upon the 17th of January 1881.

Prescott, *Hist. of the Conquest of Peru*, v. 50 Xerez, *Conquista del Perú*; and G. Zarate, *Hist. de la Conq. del Perú*, and J. de Forerster, *Hist. d'Espagne* (French translation by M. de La Harpe), Paris, 1782.

LIMA, capital of Allen county, Ohio, U.S., on the Ottawa river, and at the intersection of four railway lines, 130 miles north of Cincinnati. It is pleasantly situated

in a fine farming country, and has two large railway repairs shops, extensive car-works, and other smaller manufactures. The population in 1880 was 757; in 1860, 1939; in 1870, 4464, and in 1880, 7557.

LIMBORCH, PHILIP VAN (1633-1712), a prominent Remonstrant theologian, was born June 10, 1633, at Amsterdam, where his father held a good position in the legal profession. He received his education at Utrecht, at Leyden, in his native city, and finally at Utrecht university, which he entered in 1652. In 1657 he became a Remonstrant pastor at Gouda, and in 1667 he was transferred to Amsterdam, where, in the following year, the office of professor of theology in the Remonstrant seminary was added to his pastoral charge. He died there on April 30, 1712.

His most important work, *Institutiones theologice christianae, ad praecepta pietatis et promissiones pacis christianae unice directae* (Amsterdam, 1698, 6th ed. 1785), remains survived as a full and able exposition of the system of Episcopius and Cocceius. The fourth edition (1715) included a posthumous "Relatio historica de origine et progressu controversiarum in fœderato Belgio de praedestinatione." Limborch also wrote *De veritate religionis Christianae amice eccliae cum erudito Judio*, Gouda, 1687; *Historia Inquisitionis (1682)*, in four books prefixed to the "Liber Sententiarum Inquisitionis Tolosanae" (1807-1838), and *Commentarius in Acta Apostolorum et in Epistolae ad Romanos et ad Hebraeos*, Rotterdam, 1711. His editorial labours included the publication of various works of his predecessors, and of *Epistolae ecclesiasticae praestantissimae ac eruditissimae* (Amsterdam, 1684), chiefly by Arminius, Uytenbogaardus, Vorstius, Vosius, Grotius, Episcopius (his grand-uncle), and Barleus; they are of great value for the history of Arminianism. An English translation of the *Theologia*, with improvements, from Wilkinson, Tilson, Scott, and others, was published in the beginning of last century by W. Jones (*A Complete System or Body of Divinity, both Speculative and Practical, founded on Scripture and Reason*, London, 1709), and a translation of the *History of the Inquisition*, by S. Chandler, with a large introduction concerning the rise and progress of persecution and the real and pretended cause of it" prefixed, appeared in 1781.

LIMBURG, or LIMBOURG, one of the nine provinces of Belgium, is bounded on the N. and E. by Holland, on the S. by the province of Liège, and on the W. by those of Brabant and Antwerp; this area is 932 square miles, with a population, in 1880, of 311,694. The surface is for the most part flat, but rising somewhat towards the south-east. Most of the province is included in the barren and marshy district of sandy heath known as *La Campine* (Flem., *Kempen*). The Meuse, with a tolerably fertile valley, is its chief river. The soil is metalliferous; the chief vegetable products are cereals, leguminous plants, flax, hemp, and beetroot; and stock-breeding is largely carried on. Industries are less developed in Limburg than in the rest of Belgium; but the distilleries of the province are very considerable and noted. Limburg is divided for administrative purposes into three arrondissements, of which the capitals are Hasselt (population 11,500), Tongres (7800), and Maaseyck (4400). The last-named is the birthplace of Hubert and John van Eyck, the Flemish painters. One of the most interesting towns of the province is ST TROUV (q.v.), thought to be the ancient *Astrucum Oppidum*, the oldest town in Belgium. Near Tongres is a mineral well, described by Pliny.

The territory of Limburg was that of the *Eburones*, whom the Romans exterminated, and was afterwards inhabited by the *Franks* and *Frisians*. It was one of the first conquests of the invading Franks, who established themselves and proclaimed their first kings there. In the Middle Ages it constituted the county of Loos, holding of the bishop of Liège; afterwards it became the duchy of Limburg, which was taken possession of in 1382 by the duke of Brabant. From the 12th to the end of the 15th century the duchy included only a small portion of the present province; it extended eastward from the Meuse as far as Aix-la-Chapelle, and southward to the Vesdre. In the 18th century Limburg remained in the possession of Spain, and it passed to Austria in 1713. After the treaty of Campo Formio (1797) it was a French department, Meuse-Inférieure, with Maestricht as capital. By the treaty of

Vienna (1815) it formed one of the nineteen provinces of the kingdom of the Netherlands, and by that of London (1831) the eastern portion was ceded to Holland, becoming a Dutch province, the remainder constituting the present provinces of Belgium.

LIMBURG, or **LIMBOURG**, one of the eleven provinces of Holland, is bounded on the W. by Belgium (Limburg) and North Brabant, on the N. by North Brabant and Guelderland, on the E. by Rhinish Prussia, and on the S. by Belgium (*Liège*), and has an area of 851 square miles, with a population in 1876 of 235,135 (97 per cent. being Roman Catholics). The surface, which is flat, is partly covered with heaths and fens; of the latter the most considerable is the "peel" or marsh in the north, which extends into North Brabant. The province is traversed by the Maas, of which the chief affluent here are the Geule, the Geleen, and the Roer, all on the right; means of water communication are also supplied by the Zuid Willem's canal and its branches. The agricultural products are similar to those of Belgian Limburg; bee-keeping is also engaged in. Coal occurs within the province, and there is a mine at Kerkrade. The arrondissements are two in number,—Maastricht and Roermonde,—Maastricht being the capital. For the history of the province see the preceding article.

LIMBURG, a town in the circle of Unterlahn and district of Wiesbaden, Prussia, is situated 360 feet above the sea-level, on the Lahn, here crossed by a bridge dating from 1316, and on the Nassau Railway midway between Coblenz and Wieslar. A local branch line connects it with Hadamar. It is the seat of a Catholic bishop, and has one evangelical and four Catholic churches. The only prominent architectural feature is the small seven-towered semi-Byzantine cathedral, picturesquely situated on a rocky site overlooking the river; it was founded by Conrad Kurzbild, count of Niederlahngau, in 905, and finally consecrated in 1235 (restored 1872-78). Limburg has a seminary for the education of priests, and a variety of schools; the industries, which are unimportant, include manufactures of cloth, tobacco, machinery, pottery, and leather. The population in 1875 was 6161.

Limburg, which was a flourishing town during the Middle Ages, passed in 1404 into the possession of the archbishops of Treves after the extinction of its own line of counts, and in 1803 fell to the duke of Nassau. It was the scene of a victory of the archduke Charles of Austria over the French under Jourdan on September 16, 1796. It possesses an interesting MS. fragment of the chronicles, the *Festii Longipresens*. The original writer is supposed to have been the recorder Tillmann (ab. 1400), additions being made by subsequent copyists; the document, which has been more than once printed, is valuable especially for the ancient rhymes it embodies, and for its notices of old German poets.

LIMBUS. The *Limbus Infantum* or *Puerorum* in medieval theology is the "margin" or "border" (limbus) of hell to which human beings dying without actual sin, but with their original sin unwashed away by baptism, were held to be consigned; the category included, not unbaptized infants merely, but also idiots, cretins, and the like. The word "limbus" in the theological application, occurs first in the *Summa* of Thomas Aquinas; for its extensive currency it is perhaps most indebted to the *Commedia* of Dante (*Infer.*, c. 4). The question as to the destiny of infants dying unbaptized presented itself to theologians at a comparatively early period, and received very various answers. Generally speaking it may be said that the Greek fathers inclined to a cheerful and the Latin to a gloomy view. Thus Gregory of Nazianzus (*Orat.* 40) says "that such children as die unbaptized without their own fault shall neither be glorified nor punished by the righteous Judge, as having done no wickedness, though they die unbaptized, and as rather suffering loss than being the authors of it." Similar opinions have been expressed by Gregory of Nyssa, Severus of Antioch, and others,—

opinions which it is almost impossible to distinguish from the Pelagian view that children dying unbaptized might be admitted to eternal life, though not to the kingdom of God. In his recoil from Pelagian heresy, Augustine was compelled to sharpen the antithesis between the state of the saved and that of the lost, and taught that there are only two alternatives,—to be with Christ or with the devil, to be with Him or against Him. Following up, as he thought, his master's teaching, Fulgentius declared that it is to be believed as an indubitable truth that, "not only men who have come to the use of reason, but infants dying, whether in their mother's womb or after birth, without baptism in the name of the Father, Son, and Holy Ghost, are punished with everlasting punishment in eternal fire." Later theologians and schoolmen followed Augustine in rejecting the notion of any final position intermediate between heaven and hell, but otherwise inclined with practical unanimity to take the mildest possible view of the destiny of the irresponsible and unbaptized. Thus the proposition of Innocent III. that "the punishment of original sin is deprivation of the vision of God" is practically homologated by Thomas, Scotus, and all the other great theologians of the scholastic period, the only outstanding exception being that of Gregory of Rimini, who on this account was afterwards called "tortor infantum." The first authoritative declaration of the Latin Church upon this subject was that made by the second council of Lyons (1274), and confirmed by the council of Florence (1439), with the concurrence of the representatives of the Greek Church, to the effect that "the souls of those who die in mortal sin or in original sin only forthwith descend into hell, but to be punished with unequal punishments." Perrone remarks (*Prat. Theol.*, pt. iii. chap. 6, art. 4) that the damnation of infants and also the comparative lightness of the punishment involved in this are thus *de fide*, but nothing is determined as to the place which they occupy in hell, as to what constitutes the disparity of their punishment, or as to their condition after the day of judgment. In the council of Trent there was considerable difference of opinion as to what was implied in deprivation of the vision of God, and no definition was attempted, the Dominicans maintaining the severer view that the "limbus infantum" was a dark subterranean fireless chamber, while the Franciscans placed it in a lightsome locality above the earth. Some theologians continue to maintain with Bellarmine that the infants "in limbo" are affected with some degree of sadness on account of a felt privation; others, following Sfrondati, hold that they enjoy every kind of natural felicity, as regards their souls now, and as regards their bodies after the resurrection, just as if Adam had not sinned. In the condemnation (1794) of the synod of Pistoia (1786), the twenty-sixth article declares it to be false, rash, and injurious to treat as Pelagian the doctrine that those dying in original sin are not punished with fire, as if that meant that there is an intermediate place, free from fault and punishment, between the kingdom of God and everlasting damnation.

The *Limbus Patrum*, *Limbus Inferni*, or *Sinus Abrahæ* is defined in Roman Catholic theology as the place in the underworld where the saints of the Old Testament were confined until liberated by Christ on his "descent into hell." Regarding the locality, and its pleasantness or painfulness, nothing has been taught as *de fide*, and opinions have been various. It is sometimes regarded as having been closed and empty since Christ's descent, but other authors do not think of it as separate in place from the *limbus infantum*. The whole idea, in the Latin Church, has been justly described as the mere caput mortuum of the old catholic doctrine of hells, which was gradually superseded in the West by that of purgatory.

LIME is the name of the strongly basic monoxide CaO of the metal calcium. This base is widely diffused throughout the three kingdoms of nature in the form of salts, of which the carbonate CaCO_3 and the hydrated sulphate $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ are by far the most abundant. Both are found in the mineral kingdom in a variety of forms. Of native carbonates of lime, *calc-spar* (Iceland spar), though comparatively rare, may be mentioned first as representing the purest native form of the compound. It generally presents itself in the form of well-developed transparent colourless rhombohedra, which possess to a remarkable degree the property of producing double refraction of light, whereupon is founded its application in the construction of certain optical instruments. Of the varieties of massive or crystalline carbonate of lime, those which, through the fineness of their grain and other qualities, lend themselves for the purposes of the sculptor go by the name of marble, while the remainder are embraced under the generic term of limestone. This name, however, is understood to exclude chalk, a soft, amorphous variety which, according to Ehrenberg, consists mainly of *Foraminifera* shells. All limestones contain at least traces of magnesia. When this foreign base is present in considerable proportion the rock is termed "dolomite" (see **MAGNESIUM**). Among the native forms of (hydrated) sulphate of lime the mineral "selenite" (glacies Marie) corresponds to Iceland spar among the carbonates. It forms colourless transparent rhombohedral prisms, generally united into "twins," and flattened down into plates readily cleavable along planes parallel to the surface. Hardness ranges from 1.6 to 2; the specific gravity is 2.3. Far more common than selenite are the massive varieties known as **ALABASTER** (see vol. i. p. 439) and ordinary **GYPSEUM** (vol. xi. p. 337).

Both sulphate and carbonate of lime, apart from their occurrence as independent minerals, are almost universally diffused throughout the earth's crust, and in the waters of the ocean. Now the sulphate is appreciably soluble in even pure water, while the carbonate, though practically insoluble in pure, is quite decidedly soluble in carbonic acid water. As all atmospheric water must necessarily hold carbonic acid gas in absorption, most natural waters, and certainly all deep-well waters, are contaminated with more or less of bicarbonate or sulphate of lime, or with both. When such a water is being boiled, there is an escape of the free and the loosely combined carbonic acid, and the carbonate of lime comes down as a loose precipitate or as a "crust", and, when the water is sufficiently concentrated by evaporation, the sulphate likewise is partly deposited. The decomposition of the "bicarbonate" in fact takes place, though slowly, even at ordinary temperatures, when the water in which it is held in solution is exposed to the atmosphere. It is in this manner that stalagmites and stalactites frequently seen within rock-caverns are produced, and there is no difficulty in accounting for the grotesque and fantastic forms which the latter often exhibit.

Quicklime.—The native carbonate always serves as the starting-point in the preparation of calcium compounds. From it the oxide CaO , known as quicklime or caustic lime, is produced industrially by heating limestone or marble in kilns, between layers of fuel, which in the United Kingdom is generally coal. The carbonic acid goes away with the gaseous products of combustion, and the oxide remains in unfused lumps of the form of the original stones. Lime, when pure, is an amorphous white solid, which is absolutely infusible and non-volatile; and on this account, when raised to high temperatures, it emits a brilliant white light ("lime-light"). The commercial article is generally grey or otherwise discoloured by the presence of foreign metallic oxides.

The decomposition that goes on in a limekiln is not brought about by the effect of heat alone. Gay-Lussac found long ago that carbonate of lime, when heated to intense redness in a closely covered crucible, loses its carbonic acid only very slowly, while the acid goes off readily even at somewhat lower temperatures when a current of steam is passed over, the heated limestone. This may be accounted for by assuming that the steam, in the first instance, produces hydrate—from the carbonate—of lime, which latter then at once breaks up into its two components. More probably, however, the steam acts only by producing a *quies vacuum*, that is, by clearing out the carbonic acid which, if allowed to stagnate even at high temperatures, would react on the quicklime produced, thus preventing the decomposition of a portion of the carbonate.

Quicklime acts readily and energetically on water, with evolution of much heat (269 units per unit weight of lime, Berthelot) and formation of a bulky white powder of the hydrate Ca(OH)_2 or Ca(OH)_2 . This powder readily mixes with water into a smooth paste, which may be diluted to a milky liquid—milk of lime. This, when filtered through paper, yields "lime-water," a strongly alkaline liquid containing about $\frac{1}{17}$ th of its weight of lime (calculated as CaO). When boiled it deposits a part of its dissolved lime as such, and when exposed to ordinary air it quickly draws a skin of carbonate of lime. Hence its application as a reagent for carbonic acid, and the extensive use of milk of lime (whitewash) as a cheap white pigment in wall-painting. Lime paste, as every one knows, is most extensively used as a mortar or cement for bricks and stones in building. For this purpose it is always mixed with a certain proportion of sand. This admixture in all probability was originally intended only to save lime and prevent shrinking. But it is now generally assumed to have a chemical function, causing the formation of a hard silicate of lime pervading and thus strengthening the mortar. Some chemists deny the practical importance though not the occurrence of this silication, what admits of no doubt is that the hardening of mortar involves the very gradual conversion of the original hydrate into carbonate of lime. Under the name of plaster, a fine smooth paste of lime and sand, with short hair to increase the tenacity of the mixture, is a most important material for coating the internal walls and roofs of ordinary buildings.

Hydraulic Cements.—Ordinary mortar, on account of the solubility of lime in water, is unfit for aquatic masonry; for this purpose hydraulic cements must be used. Of these there are a great variety, which, however, mostly agree in this that they consist of calcined mixtures of limestone and clay (preferably aluminiferous clay) and other silicates. By calcining such mixtures at temperatures short of that at which a glass would be produced, the lime becomes caustic, and part of the caustic lime, by uniting with the clay (and silicate generally), forms a silicate sufficiently basic to be disintegrable by acids and even by water. When such cement, as a powder, is mixed with water, the lime acts upon the silicate of alkali and the gelatinous silica-hydrate transiently produced, and with the silica and alumina and oxide of iron units into a hard, waterproof, very complex, silicate mixture.

H. Ste. Claire Deville having found that magnesia has hydraulic properties, hydraulic cements have been made by calcining dolomites of the proper composition so far as to decompose only the carbonate of magnesia (into MgO and CO_2). See **CEMENT**, vol. v. p. 328.

Lime, being the cheapest of powerful bases, is largely used in chemical manufacturing. It serves for the causticizing of soda, for the preparation of ammonia from ammonia salts, and for the manufacture of bleaching powder. It also enters into the composition of certain kinds of glass, and is used (as lime or as carbonate), in the making of soda ash.

Lime Salts.—These can in general be prepared by the saturation of the respective acids with lime hydrate. Thus the (pure) car-

bonate CaCO_3 may be prepared by passing carbonic acid into lime-water. But a more convenient method is to decompose a solution of pure chloride of calcium with excess of carbonate of ammonia, previously at $70-80^\circ\text{C}$, when the carbonate assumes the form of a crystalline precipitate which settles readily and is easily washed with hot water. The sulphate (artificial gypsum) appears as a voluminous white precipitate, consisting of minute colourless needles, when sulphuric acid is added to a not too dilute solution of chloride of calcium or other lime salt. The precipitate $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ is appreciably soluble in water, 1000 parts of which at 0° , 35° , and 100°C dissolve 2.05, 3.54, and a little over 2 parts respectively of gypsum. The hydrated sulphate at temperatures exceeding 110°C loses its water. The anhydrous sulphate, if formed below about 200°C , readily recombines with water into compact gypsum (plaster of Paris). By exposure to high temperatures (600°C and upwards) sulphate of lime loses its power of recombining with water, at very high temperatures it fuses. A naturally anhydrous sulphate of lime (anhydrite) occurs in association with rock salt, and otherwise, as a not very common mineral.

The well-known favorable action of gypsum as a manure, more especially for clover (see AGRICULTURE), has lately been explained by Deheran on the strength of analyses and vegetation experiments of his own, by assuming that it converts the carbonate of potash of the soil into sulphate, which, being less obstinately retained by the soil, more readily finds its way into the roots of the plants.

Chloride of Calcium (sulfate of lime), CaCl_2 , is prepared by dissolving marble or limestone in aqueous muriatic acid. The iron and manganese generally present as impurities can be eliminated, after peroxidation by chlorine water, by digestion with hydrate of lime, which also, if allowed sufficient time, removes the magnesia. The filtrate is acidified with hydrochloric acid and concentrated by evaporation, so far that, on cooling, it deposits part of the dissolved porous kind of chloride of calcium which analytical chemists prefer for the drying of gases. This substance, when heated to redness—which must be done in platinum to prevent contamination—loses the rest of the water and at 729°C (O. Carrelly) fuses into the anhydrous salt CaCl_2 , which on cooling becomes into a stone-like mass. In this form chloride of calcium is much used in laboratories as a powerful dehydrating agent. It combines with ammonia gas into a solid compound. It dissolves in methyl alcohol and in ethyl alcohol, forming crystallizable "alcoholates" (Graham), compounds of CaCl_2 with "crystal alcohol".

Trihydrate of Calcium, $\text{Ca}(\text{NO}_3)_2$, crystallizing with $4\text{H}_2\text{O}$, is a very hygroscopic salt, soluble in even absolute alcohol. It is mentioned here as a material for the convenient preparation of pure lime—by simple ignition of the salt in a platinum crucible. Regarding bleaching powder, a double salt of hypochlorite and chloride of calcium $\text{O}(\text{Cl})_2$, see CHLORINE, vol. v. p. 678.

Fluoride of Calcium, CaF_2 , obtainable by precipitation of chloride of calcium with an alkaline fluoride, occurs in nature as FLUORSPAR (q.v.). Fluoride of calcium is widely disseminated throughout the mineral kingdom as an admixture with other minerals. All native forms of phosphate of lime contain it; some in considerable quantity. Traces of it are found in bones and in the scales of most plants.

Metallic Calcium cannot be prepared by the reduction of the oxide with charcoal. It may be produced, however, by the electrolysis of the fused chloride or—more conveniently—by heating the solid CaF_2 (seven parts) with calcium (one part) in a very crucible. The metal has a yellow colour; it is somewhat harder than lead, and very malleable and ductile (Litt-Bodart and Jobin). The specific gravity is 1.578 (Busen and Matthiessen). It does not tarnish in dry air, but readily decomposes water, with evolution of hydrogen and formation of hydrate of lime. It is practically non-volatile. When heated in air or oxygen it burns with a most brilliant light into oxide, CaO .

Tests—Solutions of ordinary calcium salts are not affected visibly by sulphuretted hydrogen, sulphide of ammonium, or pure ammonia. Carbonate of ammonia, even in the presence of sal-ammoniac, precipitates the carbonate of calcium between the bars and strontium. From the former it is distinguished by its not being precipitated by either hydrosulphuric acid or bichromate of potash, and from both by its spectrum and the relatively large solubility of its sulphate in water. The latter is obtained from any calcium solution by addition of sulphuric acid or alcohol. The sulphate is washed with alcohol on a filter. When then boiled with water it yields a solution which, dilute as it is, gives a very distinct pre-

cipitate with oxalate of ammonia (barium and strontium sulphates in these circumstances give negative results). Oxalate of ammonia is the most delicate precipitant for calcium, the precipitate is insoluble in water, in ammonia and ammonia salts, and in acetic acid. From solutions (in acids) of phosphate or oxalate of calcium ammoniac and likewise sulphide of ammonium precipitate the metal as phosphate or oxalate. To detect it in such a precipitate, dissolve in hydrochloric acid and add sulphuric acid and alcohol. The calcium is precipitated as sulphate, which can be identified as just explained.

For the phosphates of lime, see PHOSPHATES.

(W D)

LIME, or LINDEN. The lime trees, species of *Tilia*, are familiar timber trees with mellifluous flowers, rarely if ever maturing their fruit in England, which are borne on a common peduncle proceeding from the middle of a long bract. *T. europæa*, L., is indigenous to Europe, excepting the extreme north, and extends eastwards across Russian Asia to the Altai. The lime is much planted in Britain, and is probably wild in south and west England, and perhaps in Ireland. The truly indigenous form in north Europe is always a small-leaved one. The large leaved variety (*T. grandifolia*, Ehrh.) is of South-European origin (Bentham, *Handbook of the British Flora*, i. 157); *T. parvifolia*, L., is perhaps the English wild form of the Continental *T. europæa*, L.; while *T. intermedia*, D. C., probably a sub-species of *T. europæa*, L., is the so-called common lime (Hooker, *Student's Flora of the British Isles*, p. 76). For a full description of the European and American forms, see London, *Arboretum*, i. p. 364, and De Candolle, *Prod.* i. 513. The lime sometimes acquires a great size: one is recorded in Norfolk as being 16 yards in circumference, and Ray mentions one of the same girth. The famous linden tree which gave the town of Neustadt in Württemberg the name of "Neustadt an der grossen Linden" was 9 feet in diameter.

The economic value of the tree chiefly lies in the inner bark or liber, called bast, and the wood. The former was used for paper and mats and for tying garlands by the ancients (*Od.* i. 38; *Pliny*, xvi. 14, 25; xxiv. 8, 38). *T. grandifolia* and *T. parvifolia* have been found in the debris of lake dwellings in Switzerland. Bast mats are now made chiefly in Russia, the bark being cut in long strips, when the liber is easily separable from the corky superficial layer. It is then plaited into mats about 2 yards square, 14,000,000 come to Britain annually, chiefly from Archangel. The wood is used by carvers, being soft and light, and by architects in framing the models of buildings. Turners use it for light bowls, &c. The flowers, alone, are used for an infusion in Austria and elsewhere, with much success in vertigo and spasms, producing perspiration, and alleviating coughs, but the bracts and fruit are astringent.

The common lime was well known to the ancients. Theophrastus says the leaves are sweet and used for fodder for most kinds of cattle. Pliny alludes to the use of the liber and wood, and describes the tree as growing in the mountain valleys of Italy (xvi. 30). See also *Verg.* *Georg.* i. 178 &c.; *Cr.* *M.* vii. 521, x. 92. The *Salix* (Eid., i. 67) was the lime of the Greeks, perhaps *T. argentea* (see Pickering's *Chron. Hist. of Plants*, pp. 214, 227, 418). Allusion to the lightness of the wood is made in Aristoph., *Birds*, 1378. For the sweet lime (*Citrus Limetta*) and lime juice, see LEMON.

LIMERICK, a maritime county of Ireland, in the province of Munster, is bounded on the N. by the estuary of the Shannon and the counties of Clare and Tipperary, on the E. by Tipperary, on the S. by Cork, and on the W. by Kerry. Its greatest length from north to south is 35 miles, and its greatest breadth east and west 54 miles. The total area comprises 662,978 acres, or 1036 square miles.

The greater part of the county is comparatively level, and rests on limestone, but in the south-east the picturesque Galtees, which extend into Tipperary, and are composed of Silurian strata overlaid by Old Red Sandstone, attain in Galtymore a height of 3015 feet, and on the west stretching

into Kerry there is a circular amphitheatre of less elevated mountains composed of volcanic rocks. The Shannon is navigable to Limerick, above which are the rapids of Doonins and Castlery. The Maag, which rises in the Galtees, and flows into the Shannon, is navigable as far as the town of Adare. Limerick includes the greater part of the Golden Vale, the most fertile district of Ireland, which stretches across the county from Cash in Tipperary to near the town of Limerick. Along the banks of the Shannon there are large tracts of flat meadow land formed of deposits of calcareous and sandy matter, and possessing extraordinary fertility. The soil in the mountainous districts is, for the most part, thin and poor, and incapable of improvement. In 1880 there were 175,774 acres under tillage, 415,107 pasture, 8,407 plantations, and 62,465 waste. The total number of holdings in 1880 was 16,366, of which 1937 were less than one acre, and 11,273 between 15 and 100 acres in extent, 1019 between 100 and 200 acres, 339 between 200 and 500 acres, and 29 above 1000 acres. The large farms occupy the low grounds, and are almost wholly devoted to grazing. The following table shows the area under the principal crops in 1855 and 1881—

	Wheat	Oats	Cereals Other than Oats	Potatoes	Turneps	Other Grasses	Flax	Straw and Clover	Total
1855	17,149	15,475	12,057	25,725	11,574	2,771	213	71,292	196,651
1881	7,227	21,410	4,034	21,025	7,220	3,791	16	112,278	176,831

The table shows a remarkable increase in the area under meadow, notwithstanding which the total area under tillage has considerably decreased. The number of horses has, since 1855, declined from 17,206 to 15,389, of which 10,228 were used for agricultural purposes. Cattle have increased from 159,710 to 201,456, an average of 28 to every 100 acres under cultivation, the average for Ireland being 25.8. The number of cows was 95,225. Sheep have diminished from 80,914 to 50,599, and pigs from 61,733 to 48,801. The number of goats was 10,012, and of poultry 428,398.

According to the corrected returns of 1878, the land, exclusive of that in the county of the city of Limerick, was divided among 1576 proprietors, possessing 660,336 acres, of the annual value of £461,213, or 13s. 11d. per acre. Of the owners nearly 40 per cent possessed less than 1 acre, the average extent being 394. The following were the largest proprietors—Earl of Devon, 33,026; Earl of Dunraven, 14,298; Lord Ashton, 11,273; Archdeacon Gould, 10,936; Lady Louisa Fitzgibbon, 10,316; Sir Croker Barrington, 9485.

Manufactures—The inhabitants are employed chiefly in agriculture, but coarse woollens are manufactured, and also paper, and there are a considerable number of meal and flour mills. At one time there were a number of flax-spinning and weaving mills, but that industry is now almost wholly extinct.

Administration and Population—The county includes 14 baronies, 181 parishes, 2067 townlands, and the city and parliamentary borough of Limerick. The number of members returned to the Irish parliament was eight, two being returned for each of the boroughs of Askeaton and Kilmallock, in addition to the two returned as at present for the county, and the two returned for the county of the city of Limerick. There are three poor-law unions wholly within the county, and portions of four others. Assizes are held at Limerick, and quarter sessions at Bruff, Limerick, Newcastle, and Rathkeale. The county is within the Cork military district, with a brigade depot at Tralee. The population, estimated in 1760 at 92,376, had increased in 1821 to 277,477, and in 1841 to 331,009, but since that period it has been gradually diminishing, being 217,277 in 1861, and in 1881 only 177,208, of whom 86,541 were males and 90,662 females. The decrease since 1871 has been 7.7 per cent, the decrease per cent in Ireland being 4.7. Besides the city of Limerick, with a population in 1881 of 48,346, only two other towns, Rathkeale and Newcastle, had a population of over 2000. From 1st May 1851 to 31st December 1880 the number of emigrants

from the county was 139,333, a proportion of 66 per cent of the population in 1861.

History and Antiquities—Limerick, originally inhabited by the Corioudi, was included in the kingdom of Thomond. Afterwards it had a separate existence under the name of Aine-Cluich. From the 8th to the 11th century it was partly occupied by the Danes. By Henry II it was granted to Henry Fitzthelbert, but his claim was afterwards resigned, and subsequently various Anglo-Norman settlements were made. About 100,000 acres of the estates of the earl of Desmond, which were forfeited in 1586, were situated in the county, and other extensive confiscations took place after the Cromwellian wars. In 1709 a German colony from the Palatinates was settled by Lord Southwell near Bruff, Rathkeale, and Adare.

There are only slight remains of the round tower at Anghatrick, but that at Carrigea is much better preserved. There are important remains of stone circles, pillar stones, and altars on Loch Gull. In several places there are remains of old mounds and tumuli. Besides the monasteries in the city of Limerick, the most important monastic ruins are those of Adare Abbey, Askeaton Abbey, Kilsheane Abbey, Galbally Friary, Kilfin Monastery, Kilmallock Abbey, and Monaster-Neragh Abbey. See the *History of Limerick* by Fitzgerald and McGregor, 1828-29.

LIMERICK, a county of a city, parliamentary borough, and the chief town of the county of Limerick, is situated on both sides of the Shannon, at the head of its estuary, and on an island of the river, 120 miles west-south-west of Dublin by rail. The western bank of the river is occupied by Irish Town, the island by English Town, and the eastern bank by Newtown Pery,—the two former divisions consisting chiefly of mean houses occupied by the poorer classes, and Newtown Pery including the principal streets, shops, and public buildings. The different parts of the town are connected by several bridges, the most important of which is Wellesley bridge, erected in 1827 at a cost of £285,000. The cathedral of St Mary, founded in 1180, and rebuilt in

Plan of Limerick.

1490, is a cruciform structure in the Gothic style, with an embattled tower 120 feet in height. A Roman Catholic cathedral in the First Pointed style was erected in 1860. The other principal public buildings are the court-house, the custom-house, the exchange, the chamber of commerce, the town-hall, the county jail, the city jail, the infirmary, and Barrington's hospital. There are barracks for cavalry, artillery, and infantry. Limerick as a port occupies the fourth position in Ireland, and, while possessing secure and open communication with the Atlantic, is included in a vast network of inland navigation. Vessels of 1000 tons can unload at the floating dock, and vessels of 500 tons at the quays. A graving dock, admitting vessels of 1800 tons for repair, has lately been constructed. The value of the imports in 1880 was £237,269, the average for the four years 1876-79 being £294,279, and, for 1872-75

£373,533. For the same dates the value of the exports was £20,569, £3552, and £12,516. The principal industries are flax spinning and weaving, and the manufacture of lace and gloves. There are also breweries, distilleries, tanneries, and flour-mills. The population in 1861 was 48,901, which in 1871 had increased to 49,980, but in 1881 had diminished to 48,246.

Limerick is said to have been the ancient *Regia* of Ptolemy and the *Rosse-de-Mailtoigh* of the Annals of Mulhernan. There is a tradition that it was visited by St. Patrick in the 5th century, but it is first authentically known as a settlement of the Danes, who in the middle of the 9th century made it one of their principal towns, but were expelled from it in the 11th century by Brian Borumhe. From 1166 till its conquest by the English in 1174 it was the seat of the kings of Thomond or North Munster, and although in 1179 the kingdom of Limerick was given by Henry II. to Herbert Fitzherbert, the city was frequently in the possession of the Irish chieftains till 1195. By King John it was committed to the care of William de Burgo, who founded English Town, and for its defence erected a strong castle. The city was frequently besieged in the 13th and 14th centuries. In the 15th century its fortifications were extended to include Irish Town, and until their demolition in 1780 it was one of the strongest fortresses of the kingdom. In 1651 it was taken by General Innes, and after an unsuccessful siege by William III. in 1690 its resistance was terminated in October of the following year by the treaty of Limerick. The town first obtained municipal privileges in 1199, and these were confirmed and extended by Edward I. and other sovereigns. In 1609 it received a charter constituting it a county of a city, and also incorporating a society of merchants of the staple, with the same privileges as the merchants of the staple of Dublin and Waterford. The powers of the corporation were remodelled by the Limerick Regulation Act of 1823. The prosperity of the city dates chiefly from the foundation of Newtown Pery by Mr. Sexton Pery in 1769. It returns two members to parliament. See the *History* by Linahan, 1866.

LIMITATION, STATUTES OF, are Acts of Parliament by which rights of action are limited to a fixed period after the occurrence of the events giving rise to the cause of action. This is one of the devices by which lapse of time is employed to settle disputed claims. There are mainly two modes by which this may be effected. We may say that the active enjoyment of a right—or possession—for a determined period shall be a good title against all the world. That is the method known generally as **PRESCRIPTION** (*q.v.*). It looks to the length of time during which the defendant in a disputed claim has been in possession or enjoyment of the matter in dispute. On the other hand, the principle of the statutes of limitation is to look to the length of time during which the plaintiff has been out of possession. The point of time at which he might first have brought his action having been ascertained, the lapse of the limited period after that time bars him for ever from bringing his action. In both cases the policy of the law is expressed by the maxim *Interest reipublice ut sit finis litium*.

The principle of limitation was first adopted in English law in connexion with real actions, *i.e.*, actions for the recovery of real property. At first a fixed date was taken, and no action could be brought of which the cause had arisen before that date. By the Statute of Westminster the First (3 Edward I. c. 39), the beginning of the reign of Richard I. was fixed as the date of limitation for such actions. This is the well known "period of legal memory" recognized by the judges in a different class of cases to which a rule of prescription was applied. Possession of rights *in alieno solo* from time immemorial was held to be an indefeasible title, and the courts following the statutes above mentioned held time immemorial to begin with the first year of Richard I.

A period absolutely fixed became in course of time useless for the purposes of limitation, and at last the method of counting back a certain number of years from the date of the writs was adopted in the Statute 32 Henry VIII. c. 2, which fixed periods of thirty, fifty, and sixty

years for various classes of actions named therein. A large number of statutes since that time have established periods of limitation for different kinds of actions. Of those now in force the most important are 21 James I. c. 16 for personal actions in general, and 3 & 4 Will. IV. c. 27 relating to actions for the recovery of land. The latter statute has been repealed and virtually re-enacted by the Real Property Limitation Act, 1874, which reduced the period of limitation from twenty years to twelve, for all actions brought after the 1st January 1879. The principal section of the Act of Will. IV. will show the *modus operandi*—"After the 31st December 1833, no person shall make an entry or distress, or bring an action to recover any land or rent but *within twenty years next after the time* at which the right to make such entry or distress or to bring such action shall have first accrued to some person through whom he claims, or shall have first accrued to the person making or bringing the same." Another section defines the times at which the right of action or entry shall be deemed to have accrued in particular cases, *e.g.*, when the estate claimed shall have been an estate or interest in reversion, such right shall be deemed to have first accrued at the time at which such estate or interest became an estate or interest in possession. Thus suppose lands to be let by A to B from 1850 for a period of fifty years, and that a portion of such lands is occupied by C from 1851 without any colour of title from B or A—C's long possession would be of no avail against an action brought by A for the recovery of the land after the determination of B's lease. A would have twelve years after the determination of the lease within which to bring his action, and might thus, by an action brought in 1891, disestablish a person who had been in quiet possession since 1831. What the law looks to is not the length of time during which C has enjoyed the property, but the length of time which A has suffered to elapse since he might first have brought his action.

It is to be observed, however, that the Real Property Limitation Act does more than bar the remedy. It distinguishes the right, differing in this respect from the other Limitation Acts, which, while barring the remedy, preserve the right, so that it may possibly become available in some other way than by action.

By section 14 of the Act of Will. IV., "when any acknowledgment of the title of the person entitled shall have been given to him or his agent in writing signed by the person in possession, or in receipt of the profits or rent, then the right of the person (to whom such acknowledgment shall have been given) to make an entry or distress or bring an action shall be deemed to have first accrued at the time at which such acknowledgment, or the last of such acknowledgments, was given. By section 15, persons under the disability of infancy, lunacy, or coverture, or beyond seas, and their representatives, are to be allowed ten years from the termination of this disability, or death (which shall have first happened), notwithstanding that the ordinary period of limitation shall have expired.

By 21 James I. c. 16, actions of trespass, detinue, trover, replevin, or account, actions on the case (except for slander), actions of debt arising out of a simple contract, and actions for arrears of rent not due upon specialty, shall be limited to six years from the date of the cause of action. Actions for assault, menace, battery, wounds, and imprisonment are limited to four years, and actions for slander to two years. Persons labouring under disabilities are allowed the same time after the removal of the disability. When the defendant is "beyond seas" (*i.e.*, outside the United Kingdom and the adjacent islands) a similar extension of time is allowed.

An acknowledgment, whether by payment on account or by mere spoken words, was formerly sufficient to take

the case out of the statute. The Act 9 Geo. IV. c. 14 (Lord Tenterden's Act) requires any promise or admission of liability to be in writing and signed by the party to be charged, otherwise it will not bar the statute.

Contracts under seal are governed as to limitation by 3 & 4 William IV. c. 42, which provides that actions for rent upon any indenture of demise, or of covenant, or debt, or any bond or other specialty, and on recognizances, must be brought within twenty years after cause of action. Actions of debt on an award (the submission being not under seal), or for a copyhold fine, or for money lent on a writ of *fiel i facias*, must be brought within six years.

Of the miscellaneous limitations fixed by various Acts, the following may be noticed. Suits and indictments under penal statutes are limited to two years if the forfeiture is to the crown, to one year if the forfeiture is to the common informer. Penal actions by persons aggrieved are limited to two years (3 & 4 Will. IV. c. 42). Actions brought against a justice of the peace for acts done in the execution of his office are limited to six calendar months (11 & 12 Vict. c. 44). Acts done under any local or personal Act of Parliament can only be sued upon within two years (5 & 6 Vict. c. 97).

A defence under the statutes of limitations must in general be specially pleaded. Limitation is regarded strictly as a law of procedure. The English courts will therefore apply their own rules to all actions, although the cause of action may have arisen in a country in which different rules of limitation exist. This is also a recognized principle of private international law.

United States—The principle of the statute of limitations has passed with some modification into the statute-books of every State in the Union except Louisiana, whose laws of limitation are essentially the prescriptions of the civil law drawn from the *Partidas*, or "Spanish Code." As to personal actions, it is generally provided that they shall be brought within a certain specified time—usually six years or less—from the time when the cause of action accrues, and not after, while for land the "general if not universal limitation of the right to bring action or to make entry is to twenty years after the right to enter or to bring the action accrues" (Bouvier's *Law Dictionary*, art. "Limitations"). The constitutional provision prohibiting States from passing laws impairing the obligation of contracts is not infringed by a law of limitations, unless it bars a right of action already accrued without giving a reasonable term within which to bring the action. (E. R.)

LIMOGES, capital of the department of Haute Vienne, France, and the ancient capital of Limousin, lies in the form of an amphitheatre on the right bank of the Vienne, 248 miles by rail south-south-west from Paris, on the Paris and Toulouse Railway, at its junction with the Charente line. It has also direct railway communication by Bellac with Poitiers. The population in 1876 was 59,011. In spite of many modern improvements and cleanances, commencing with the administration of Turgot in 1762, the city still contains old quarters, which are dark, wretched, and unhealthy.

The cathedral, the most remarkable building, not only in the town but in the entire province, is in the Parisian Ogival style, and occupies the site of an old heathen basilica, which, according to tradition, was transformed into a Christian church by St. Martial. The present edifice was built between 1273 and 1327, and has been quite recently restored, the north front of the transept, distinguished by the richness and perfection of its details, having been finally completed in 1851. The campanile is an elegant slightly leaning tower, 204 feet high. The interior of the church is remarkable for the boldness and elegance of its construction. It has a magnificent rood-loft, attributed to Bishop

Jean de Langeac (1533); close by the choir screen is the mausoleum of the same prelate. The glass was repaired in the 16th century, but is still undergoing restoration. Under the choir is the crypt of the old Roman church, containing frescoes of the 11th century. Some of the houses still standing in Limoges date from the Middle

Plan of Limoges.

Agés; and commemorative tablets mark the birthplace of the chancellor D'Aguesseau and of Marshals Jourdan and Bugeaud. There is a museum of painting and sculpture, and, in connexion with the local industry, a very valuable ceramic museum. Limoges is the headquarters of the 12th army corps, and is also the seat of several learned societies, and of a court of appeal.

The principal industry is the manufacture of porcelain. The kaolin of St Yrieix is of such superior quality that it is exported even to America; the pegmatite used for enamel is obtained at Chanteloube, about 25 miles from Limoges, on the Paris railway. Thirty-five factories with eighty furnaces and fifty-four painting rooms (800 artists) employ 5800 workers of both sexes, and produce goods to the annual value of 12 millions of francs. There are many others in the immediate neighbourhood of the town. Limoges has also wool and cotton spinning-mills, and cloth factories, paper-works, foundries, &c. Shoemaking gives employment to 600 persons, and the manufacture of clogs to 250. There is an extensive trade in wine and spirits, cattle, cereals, and wood. The Vienne is navigable for rafts above Limoges, and the logs brought down by the current are stopped at the entrance of the town by the inhabitants of the Navexis quarter, who form a special guild for this industry.

Limoges was a place of importance even at the time of the Roman conquest, and sent ten thousand soldiers to the defence of Alesia. In 11 n.c. it took the name of Augustus (*Augustonem*), but in the 4th century it was again called by the name of the *Lemovices*, whose capital it was. It then contained palaces and baths, had its own senate and the right of coinage (711 1837 it had a mint). Christianity was introduced by St. Martial. In the 6th century Limoges was devastated by the Vandals and the Visigoths. Viscounts were set over it by Clovis. It suffered again in the wars between the Franks and the people of Aquitaine, from Nerian

invasion, and from a struggle which arose between two parties into which the city was divided, led by the abbot of St Martial and by the bishop respectively. During the Hundred Years' War it was taken again and again by the French and English. Confiscated under John Lackland, it was again seized by Louis IX. In 1370 the Black Prince took it by assault, and gave it up to fire and sword, — a disaster from which it was slow to recover. The religious wars, pestilence, and famine desolated it in turn, but the ravages of all these were surpassed by the plague of 1630-31, which carried off more than twenty thousand persons. The wise administrations of Henri d'Angouleme, father of the chancellor, and of Turgot enabled Limoges to recover its former prosperity. There have been several noteworthy conflagrations, destroying whole quarters of the city, built, as it then was, of wood. That of 1790 lasted for two months, and destroyed one hundred and ninety-nine houses, that of 1804 laid under ashes an area of 10,000 square metres. Limoges celebrated every seven years a curious religious festival (*Fête d'Octonion*), during which the relics of St Martial are exposed for seven weeks, attracting large numbers of visitors. It dates from the 10th century, and commemorates a pestilence (*mal des ardois*) which, after destroying forty thousand persons, is believed to have been stayed by the intercession of the saint.

LINACRE, or LYNACER, THOMAS (1460-1534), a distinguished humanist and physician, was born at Canterbury about the year 1460. Of his parentage or descent nothing certain is known. He received his early education at the cathedral school of Canterbury, then under the direction of William of Selling, afterwards prior of Canterbury. Selling was an ardent scholar, and one of the earliest in England who cultivated Greek learning. From him Linacre must have received his first incentive to this study, in which he afterwards became eminent. Linacre entered the university of Oxford about the year 1480, and in 1484 was elected a fellow of All Souls' College. Shortly afterwards he visited Italy in the train of William of Selling, who was sent by Henry VIII. as an envoy to the papal court, and accompanied his patron as far as Bologna. There he became the pupil of Angelo Poliziano, and afterwards shared the instruction which that great scholar imparted at Florence to the youthful sons of Lorenzo de' Medici. The younger of these princes became Pope Leo X., and was in after years mindful of his old companionship with Linacre.

Among his other teachers and friends in Italy should be mentioned Demetrius Chalcondylas, Hermolaus Barbarus, Aldus Romanus the printer of Venice, and Nicolaus Leoniconius of Vicenza. Linacre took the degree of doctor of medicine with great distinction at Padua. On his return to Oxford, full of the learning and imbued with the spirit of the Italian Renaissance, he formed one of the brilliant circle of Oxford scholars, including Colet, Grocyen, and William Latimer, who are mentioned with so much warm eulogy in the letters of Erasmus.

Linacre does not appear to have practised or taught medicine in Oxford. About the year 1501 he was called to court as tutor of the young prince Arthur, and continued to act in this capacity till the prince's death in 1503. On the accession of Henry VIII. he was appointed the king's physician, an office at that time of considerable influence and importance, and practised medicine in London, having among his patients most of the great statesmen and prelates of the time, as Wolsey, Warham, and Fox.

After some years of professional activity, and when in advanced life, Linacre received priest's orders. But, as he had for some years previously held several clerical benefices, it would seem that he must have been already a deacon, and thus nominally at least a cleric, but this status would not in those days have interfered with his practising as a physician. There is no doubt, however, that his ordination as priest was connected with his retirement from active life. Literary labours, and the care of the foundation which owed its existence chiefly to him, the Royal College of Physicians, occupied Linacre's remaining years till his death in 1524.

Linacre was more of a scholar than a man of letters, and rather a man of learning than a scientific investigator. It is difficult now to judge of his practical skill in his profession, but it was evidently highly esteemed in his own day, and several instances are recorded of his wise, prompt, and judicious treatment. He took no part in political or theological questions, and died too soon to have to declare himself on either side in the formidable controversies which were even in his lifetime beginning to arise.

But his career as a scholar was one eminently characteristic of the critical period in the history of learning through which he lived. He was one of the first Englishmen who studied Greek in Italy, whence he brought back to his native country and his own university the lessons of the "New Learning." His teachers, who have already been named, were some of the greatest scholars of the day. Among his pupils was only — Erasmus — whose name alone would suffice to preserve the memory of his instructor in Greek, and others of note in letters and politics, such as Sir Thomas More, the lamented Prince Arthur, and Queen Mary. Colet, Grocyen, William Lilye, and other eminent scholars were his intimate friends, and he was esteemed by a still wider circle of literary correspondents in all parts of Europe.

Linacre's literary activity was displayed in two directions, in pure scholarship and in translation from the Greek. In the domain of scholarship he was known by the rudiments of (Latin) grammar composed in English for the use of the Princess Mary, and afterwards translated into Latin by George Buchanan, and by a work on Latin composition, *De emendata structura Latinæ orationis*, which enjoyed a wide popularity. It was originally composed for the use of St Paul's school, when founded by Dean Colet, but was set aside as unsuited for the purpose. It was, however, printed in London, in 1524, and many times reprinted on the Continent.

Linacre's only medical works were his translations. It was the cherished project of his life to make the works of Galen (and indeed those of Aristotle also) accessible to all readers of Latin. What he effected in the case of the first, though not trifling in itself, is inconsiderable as compared with the whole mass of Galen's writings, and of his translations from Aristotle, some of which are known to have been completed, nothing has survived. The following are the works of Galen translated by Linacre: — (1) *De emendata structura Latinæ orationis*, Paris, 1519; (2) *Methodus Medendi*, Paris, 1519; (3) *De Temperamentis et de Inequali Intemperie*, Cambridge, 1521; (4) *De Naturalibus Facultatibus*, London, 1523; (5) *De Symptomatum Differentiis et Causis*, London, 1524; (6) *De Pulsum*, London, without date. He also translated for the use of his pupil Prince Arthur an astronomical treatise of Ptolemy, *De Sphæra*, which was printed at Venice by Aldus in 1499. The accuracy of these translations and their elegance of style were universally admitted. They have been generally accepted as the standard versions of those parts of Galen's writings, and frequently reprinted, either as a part of the collected works or separately.

But the most important service which Linacre conferred upon his own profession and science was not by his writings. To him was chiefly owing the foundation by royal charter of the College of Physicians in London, which first gave the medical profession in this country a recognized legal status, and which has been the model of all the similar colleges of physicians and surgeons in the three kingdoms. He was the first president of the new college, which he further aided by conveying to it his own house, and by the gift of his library. Shortly before his death Linacre obtained from the king letters patent for the establishment of readerships in medicine at Oxford and Cambridge, and placed some valuable estates in the hands of trustees for their endowment. Two readerships were founded in Morton College, Oxford, and one in St John's College, Cambridge, but owing to neglect and bad management of the funds, they fell into uselessness and obscurity. The Oxford foundation was revived by the university commissioners in 1553 in the form of the Linacre professorship of anatomy. Fortunate has done justice to the generosity and public spirit which prompted these foundations; and it is impossible not to recognize a strong constructive genius in the scheme of the College of Physicians, by which Linacre not only first organized the medical profession in England, but impressed upon it for some centuries the stamp of his own individuality. The intellectual fastidiousness of Linacre, and his habits of minute accuracy were, as Erasmus suggests, the chief cause why he accomplished so little and left behind no more permanent literary memorials. It will be found, perhaps, difficult to justify by any extant work the extremely high

reputation which he enjoyed among the scholars of his time. His Latin style was so much admired that, according to the flattering eulogium of Erasmus, Galen spoke better Latin in the version of Linacre than he had before spoken Greek; and even Aristotle displayed a grace which he hardly attained to in his native tongue. Erasmus himself also Linacre's critical judgment (*vir non evecti tantum sed severi pulcrit*). According to others it was hard to say whether he were more distinguished as a grammarian or a rhetorician. Of Greek he was regarded as a consummate master, and he was equally eminent as a "philosopher," that is, as learned in the works of the ancient philosophers and naturalists. In this there may have been, as the custom of the day was, some exaggeration; but all have acknowledged the elevation of Linacre's character, and the fine moral qualities summed up in the epitaph written by John Caius:—"Frenuolus doloresque mifer perens; fidus amicus, amantibus ordinatus iuxta carum."

The materials for Linacre's biography are to a large extent contained in the older biographical collections of George Lilly (*On Paulus Jovius, Eusebio Brilioniensis*), Haly, Leland, and Pitt, in Wood's *Athenae Oxonienses*, and in the *Biographia Britannica*, but all are completely collected in the *Life of Thomas Linacre*, by Dr. Noble Johnston, London, 1855. Reference may also be made to Dr. Munk's *Roll of the Royal College of Physicians*, 3d ed., London, 1878, and the *Introduction*, by Dr. Payne, to a facsimile reproduction of Linacre's version of *Galien de Temperamentis*, published by Messrs Moonlight, Gussall, W. With the exception of this treatise, none of Linacre's works or translations has been reprinted in modern times. (P. F. 2)

LINARES, an important mining town in the province of Jaen, Spain, is situated in an acid plain, near the foot of the Sierra Morena, 24 miles north-east from the town of Jaen, 12 north-east from that of Baza, and half an hour by rail from the Vadollano station of the Madrid and Cordova line. The streets are ill paved, irregular, and ugly, and, apart from a fine fountain of Roman origin, the town presents no architectural features of interest. There is some trade in the oil and wine of the neighbourhood, which are excellent and plentiful, wool is exported to Catalonia and Valencia; and cattle-breeding, especially of animals for the bull-ring, is also carried on. But the population, which in 1877 numbered 36,630, and includes some 120 English, with a consul and a chaplain, is chiefly engaged in the working of the extensive lead-mines to the north-west of the town, and in various concomitant industries, such as the manufacture of gunpowder, dynamite, match for blasting purposes, rope, and the like. The mining plant is entirely imported, principally from England. In respect of the quantity and uniform excellence of their productions the lead-mines of the province of Jaen are unsurpassed. For the year 1876-77 the joint output of those of Linares, Vilches, Bailen, Carboneros, Santa Helena, and (in part) La Carolina was stated at 1,630,000 cwts. of ore, worth upwards of £800,000,—the proportion of silver to lead varying from 30 to 60 grammes of the former to every 50 kilogrammes of the latter. The best class of ore is exported, chiefly to France and Belgium; the inferior classes are smelted for the most part in Spain. About 2 miles to the south of Linares in the village of Cazalona, which still shows some remains of the ancient Castulo; and the ancient mines some 5 miles to the north, which are now known as "Los Pozos de Anibal," may with some probability be assigned to the Carthaginian period.

LINCOLN, one of the four eastern maritime counties of England, lies between 52° 39' and 53° 43' N. lat., and 0° 22' E. and 0° 56' W. long. It is bounded on the N. by the Humber, E. by the German Ocean and the Wash, S.E. for 3 miles by Norfolk, S. by Cambridge and Northampton, S.W. by Rutland, W. by Leicestershire and Nottingham, and N.W. by Yorkshire. Its greatest length north and south, from Barton-on-Humber to Market Deeping, is 75 miles, its greatest breadth, from Wroton to the west to Saltfleet on the east, is 50 miles, its circuit about 260 miles. Its area is 1,767,962 acres, or about 2762 square miles, making it the second largest county in England.

Coast-Line.—The coast-line, about 110 miles in length, is low and marshy, and artificial banks for guarding against the inroads of the sea are to be found, in places, all along the coast. From Grimsby to Skegness traces of a sub-

marine forest are visible; but while the sea is encroaching upon some parts of the coast it is receding from others, as shown by Holbeach, which is now 6 miles from the sea. Several thousand acres have been reclaimed from this part of the Wash, and round the mouth of the Nene on the south-east. The deep bay between the coasts of Lincolnshire and Norfolk, called the Wash, is full of dangerous sandbanks and silt, the navigable portion, of the Lincolnshire coast, is known as the Boston deeps. The rapidity of the tides in this inlet, and the lowness of its shores, which are generally indistinct on account of mist from a moderate offing, render this the most difficult portion of the navigation of the east coast of England.

Surface and Geology.—The surface of Lincolnshire is generally a large plain, some portions of which are below the level of the sea. The south-east parts are perfectly flat, and about one-third of the county consists of fens and marshes, intersected in all directions by artificial drains, called locally dykes, delphs, drains, becks, leams, and eaus. This flat surface is, however, broken by two ranges of calcareous hills running north and south through the county, and known as the Cliff and the Wolds. The former range, on the west, runs nearly due north from Grantham to Lincoln, and thence to the Humber, traversing the Heaths of Lincolnshire, which were formerly open moors, rabbit warrens, and sheep walks, but are now enclosed and brought into high cultivation. Parallel with this range on the east side of it runs the old Roman Ermine Street, sometimes called the Cliff Row Road. The Wolds form a ridge of bold hills extending from Spilsby to Barton-on-Humber for about 40 miles, with an average breadth of about 8 miles. Between the Wolds and the sea lie the Marshes, a level tract of rich alluvial soil extending from Barton-on-Humber to Waufleet, varying in breadth from 5 to 10 miles. Between the Welland and the Nene in the south-east of the county are Gedney Marsh, Holbeach Marsh, Moulton Marsh, and Sutton Marsh.

The Fens, the soil of which has been formed partly by tidal action and partly by the decay of forests, occupy the Isle of Axholme on the north-west, the vale of Ancholme on the north, and most of the county south-east of Lincoln. The chief of these are the Holland, Wildmore, West, and East Fens draining into the Witham; and the Deeping, Bourn, Great Fownd, and Whapload Fens draining into the Welland. Owing to the dead level of these districts there is perhaps more artificial drainage in Lincolnshire than in any other English county; and thus part of the country resembles in many respects, especially in embankments and dykes, the continental Holland.

The drainage of the Fens appears to have early occupied attention Shortly after the Norman Conquest Richard de Rulois, lord of Brum, and chamberlain to William I., enclosed and drained a large part of Deeping Fen in so complete a manner that the work would not be surpassed by a comparison with the more scientific efforts of modern times. Excluding the Welland by a bank, he changed "deep lakes and impassable fens into most fruitful fields and pastures, and the most humil and moorish parts thereof into a garden of pleasure."

The drainage of the remaining levels of Lincolnshire was chiefly commenced in the reigns of James I. and Charles I. The East, West, and Wildmore Fens were contracted for in the 7th Charles I. The earl of Lindsey undertook all the fens in Holland and Kesteven, north of the River Glen up to Lincoln, on the completion of which 34,000 acres were awarded to him. In the 13th of the same reign, the king declared himself the "undertaker" of the Holland Fen, containing 22,000 acres, out of which he was to have 8000 for his share. Sir John Manners with other freeholders drained the Ancholme level in the north, and had 5827 acres assigned to them. In the same reign the Isle of Axholme was undertaken by Cornelius Vermuyden and his Dutch and Flemish followers. These operations were interrupted during the civil wars, and many of the works destroyed by the "still-walkers," so curiously described by Camden. Little was done towards restoring the works thus destroyed till the middle of the 18th century, when several townships, having a right of common over particular fens, began to join in procuring Acts of

Parliament for their drainage, enclosure, and division. The Holland Fen was the first to be dealt with, about 1788; in spite of renewed and potent opposition from the "stilt-walkers," all the fen lands were successfully drained and enclosed, and on the completion of the East, West, and Widmore Fens (about 60,000 acres) the race of "stilt-walkers" became extinct. The low lands adjoining the tidal reaches of the Trent and Humber, and part of those around the Wash, have been raised above the natural level, and enriched by the process of warping, which consists in letting the tide run over the land, and retaining it there a sufficient time to permit of the deposit of the sand and mud held in solution by the waters.

The general appearance of the county is very pleasing. The level tracts are richly cultivated; the hills and dales are interspersed with wood and lawn; and many spots on the Cliff or Wolds command extensive and charming views. The charms of the Fen districts are described as "a beauty as of the sea, of boundless expanse and freedom" (Kingsley). Not a few passages in the writings of Tennyson (a native of the county) bear the impress of the scenery and colourings of the Fens.

The geological formations, for the most part, extend in parallel belts, nearly in the line of the length of the county, from north to south, and succeed one another, in ascending order, from west to east.

1. The lowest is the *Triassic* or *New Red Sandstone* found in the Isle of Axholme and the valley of the Trent in the form of marls, sandstone, and gypsum. The presence of the porphyry of iron which tinges the beds red seems to have been prejudicial to animal life; therefore few fossils are found. Fish scales and teeth, with bones and footprints of the *Labyrinthodon*, are to be met with in the sandstone. The red clay is frequently dug for brick-making. The beds dip gently towards the east. At the junction between the Triassic and Lias are series of beds termed *Rhætic*, which seem to mark a transition from one to the other. These beds are in part exposed in pits near Newark, and extend north by Gainsborough to where the Trent flows into the Humber, passing thence into Yorkshire. The characteristic shells are found at Lea, 2 miles south of Gainsborough, with a thin stratum of bone bed full of fish teeth and scales.

2. The *Lower Lias* comes next in order, with a valuable bed of *nostons* now largely worked. This bed is about 27 feet in thickness, and crops out at Southorpe, where the workings are open and shallow. The *Middle Lias*, which enters the county near Wootton, is about 20 or 30 feet thick, and is very variable both in thickness and mineralogical character. The *Upper Lias* enters the county at Stunby, passing by Grantham and Lincoln. It forms the west slope of the Cliff range, and is thickest upon the highest hills. The Lias thus occupies a band about 6 or 10 miles in width in the south, narrowing until on the Humber it is about a mile wide.

3. To this succeed the three *Oolite* formations. The *Lower Oolite*, somewhat narrower than the Lias, extends from the boundary with Rutland due north past Lincoln to the vicinity of the Humber. The *Middle Oolite*, very narrow in the south near Wiltshire, widening suddenly about Sleaford, and then suddenly contracting again south of Lincoln, sends out a narrow band south-east towards Spilsby. It then proceeds north from Lincoln with decreasing width to the vicinity of the Humber. The *Upper Oolite* and *Kimberidge* clay start from the vicinity of Stamford, and after attaining their greatest width near Horncastle, run north-north-west to the Humber.

4. In the *Ordovician* system of the Wolds, the *Lower Greensand* runs nearly parallel with the *Upper Oolite* past South Willingham to the Humber. The *Upper Greensand* and *Gault* run north-west from Irby, widening out as far as Kelso in the east, and cross the Humber. The *Chalk* formation, about equal in breadth to the three preceding, extends from Burgh across the Humber.

5. All the rest of the county, comprising all its south-east portions between the Middle Oolite belt and the sea, all its north-east portion between the Chalk belt and the sea, and a narrow tract up the course of the Ancholme river, consists of alluvial deposits or of reclaimed marsh.

Minerals.—Gypsum is dug in the Isle of Axholme, whiting is made from the chalk near the shores of the Humber, and lime is made on the Wolds. Freestone is quarried around Auster, and good oolite building stone is quarried near Lincoln and other places. Ironstone is found and worked at Claxby near Caistor, and carried into Yorkshire to be smelted; it is also worked at Frodingham, 9 miles north-north-west of Brigg.

Rivers.—The Humber separates Lincolnshire from Yorkshire. Its ports on the Lincolnshire side are Barton, New

Holland, and Grimsby. The Trent divides the Isle of Axholme from Lindsey, and falls into the Humber about 30 miles below Gainsborough. Like the Severn, it is noted for a tidal phenomenon called the "eager" or bore, which, at spring tides, rises to the height of from 6 to 8 feet. The *Widham* rises on the south-west border of the county, flows north past Grantham to Lincoln, and thence east and south-east to Boston, after a course of about 80 miles. This river was once noted for its silt. The *Welland* rises in north-west Northamptonshire, enters the county at Stamford, and, after receiving the *Glen*, flows through an artificial channel into the *Fossdyke* Wash. The *Nene* on the south-east has but a small portion of its course in Lincolnshire, it flows due north through an artificial outfall called the *Wisbech* Cut.

Canals.—The principal canals are—the *Stainforth* and *Keadby*, connecting the Trent with the Yorkshire coal-field; the *Louth Navigation*, from Louth to Tetney Haven; the *Sleaford Navigation*, connecting Sleaford with the *Witham*; and the *Grantham Canal*, from that town to the Trent at Nottingham. The remainder are chiefly small rivers artificially deepened and embanked.

Climate.—The climate of the higher grounds is now noted for its salubrity, and meteorological observation does not justify the reputation for cold and damp often given to the county as a whole. The mean annual temperature of the Fens as given by ten years' observation (1864-73) is 47°·9, 1°·6 below that of Greenwich. The rainfall of the Fen district is very small as compared with other parts of England. While the average of the whole country was little over 30 inches, at Boston the average fall from 1830 to 1849 was 23·58 inches, and from 1850 to 1869 22·08. At *Wisbech* south-west winds prevail on an average six months in the year, and north-east winds barely two months.

Soil and Agriculture.—The soils vary considerably, according to the geological formations; ten or twelve different kinds may be found in going across the country from east to west. A good sandy loam is common in the Heath division; a sandy loam with chalk, or a stony loam on chalk marl, abounds on portions of the Wolds; an argillaceous sand, merging into rich loam, lies on other portions of the Wolds; a black loam and a rich vegetable mould cover most of the Isle of Axholme on the north-west; a well-reclaimed marine marsh, a rich brown loam, and a stiff cold clay variously occupy the low tracts along the Humber, and between the north Wolds and the sea; a peat earth, a deep sandy loam, and a rich scaly blue clay occupy most of the east and south Fens; and an artificial soil, obtained by "warping," occupies considerable low strips of land along the tidal reaches of the rivers. The wide grazing lands of Lincolnshire have long been famous, and the arable lands are specially adapted for the growth of wheat and beans. There is no generally recognized rotation of crops. The cattle raised are the *Shorthorns* and improved *Lincolnshire* breeds. The dairy, except in the vicinity of large towns, receives little attention. The sheep are chiefly of the *Lincolnshire* and large *Leicestershire* breeds, and go to the markets of Yorkshire and the metropolis. Lincolnshire has long been famous for a fine breed of horses both for the saddle and draught. Horse fairs are held every year at Horncastle and Lincoln. Large flocks of geese were formerly kept in the Fens, but their number has been diminished since the drainage of these parts. Where a large number of them were bred, nests were constructed for them one above another; they were daily taken down by the gooseherd, driven to the water, and then reinstated in their nests, without a single bird being misplaced. Decoys were once numerous in the undrained state of the Fens.

According to the agricultural returns for 1881, the total area under crops comprehended 1,498,676 acres, a percentage of 84.7 instead of 81.7 in 1870, corn crops had an area of 611,977 acres, a percentage of 34.6 instead of 34.9 in 1870, green crops, 288,719 acres, a percentage of 18.6 instead of 18.2 in 1870; rotation grasses, 167,502 acres, a percentage of 9.4 instead of 9.4, permanent pastures, 440,422 acres, a percentage of 24.9 instead of 24.8. The area under crops is thus more than three times the amount under pasturage. The area under woods in 1881 was 39,431 acres, and under orchards 1788, under market gardens 860, under nurseries gardens 137. Of the corn crops the most largely grown is wheat, which in 1881 occupied 245,646 acres,—barley or bere, grown mostly on the Wolds and the Heath districts, coming next with 199,900 acres; then oats, 118,664 acres; lastly rye, 1800 acres. Beans occupied 41,078 acres, peas 10,496 acres. Of the green crops the most largely grown in 1881 were turnips and swedes, 142,800 acres, mostly on the Wolds and Lincoln Heath. Potatoes occupied 36,794 acres, mangold, 21,438; vetches and other green crops, except clover or grass, 18,615 acres; cabbage, kohlrabi, and rape, 16,057 acres, carrots, 1516 acres. Onions are raised to a great extent in the Isle of Axholme, and under good management have been known to return £50 per acre. Flax occupied 855 acres, and hops 3. The bare fallow or uncropped arable land in 1881 was 39,865 acres. In 1870, 81.7 per cent of

Manufactures and Trade.—The manufactures are few and comparatively small. There are, however, some large agricultural machine and steam-engine factories in and around Lincoln; and similar works exist at Boston, Gainsborough, Grantham, and Louth. At Frodingham there are extensive iron-works. At Little Bytham a very hard brick, called the adamantine clinker, is made of the silicious clay that the Romans used for their manufactures of pottery. At Louth there is a carpet manufactory, also several tanneries and iron foundries. Bone crushing, leather working, the manufacture of oil-cake for cattle, rope making, and sack weaving are carried on in various places. The chief ports are Grimsby, Boston, Sutton Bridge, and Gainsborough, the first being by far the most important. For the fisheries of GAINSBY see vol. ix. p. 249.

Railways.—The first line opened in the county was the Midland Railway to Lincoln, in August 1846. The Manchester, Sheffield, and Lincolnshire Railway, first opened in 1848-49, goes from Lincoln north-east to Market Rasen, and thence, by way of Barnetby and Ulceby junctions, to Grimsby and Cleethorpes. A second branch runs north-east from Gainsborough to New Holland and Barton on the Humber, and a third from Barnetby due west to the Yorkshire coal-fields. The Great Northern main line runs through the south-west of the county past Grantham to Newark, and throws off several branches. A loop line connecting Spalding, Boston, and Lincoln with the direct line from London to York was opened in 1848. The East Lincolnshire Railway (leased to the Great Northern) runs from Boston to Grimsby.

Administration.—The primary divisions of Lincolnshire are three trithings or ridings. The north division constitutes the Parts of Lindsey, the south-west the Parts of Kesteven, and the south-east the Parts of Holland. Each of these divisions had before the Norman Conquest its own trithing courts or reeve, and to this day each has its separate trithing, quarter sessions, clerk of the peace and treasurer, but they are all under one lord-lieutenant and one sheriff, and subject to the court of assize held at Lincoln. These "Parts" are again subdivided into wapentakes, soke, and hundreds. The trithings do not in any way coincide with parliamentary divisions. The Parts of Lindsey comprise more than half the county, and contain seventeen wapentakes. The Parts of Kesteven, exclusive of the soke and borough of Grantham and the borough of Stamford, comprise nine wapentakes. The Parts of Holland comprises three wapentakes only. Before the passing of the Reform Act of 1832 Lincolnshire sent twelve members to parliament—two for the county, two for the city of Lincoln, and

the entire area of Lincolnshire was returned as cultivated, in 1879, 84.1 per cent, and in 1880, 84.5. The number of horses used solely for agriculture in 1881 was 49,366; mares and unbroken heifers, 15,171—total, 64,537. The number of cows and heifers in milk or in calf in 1881 was 53,496, and of other cattle 166,706. The number of sheep was 1,836,147, or 90.2 for every 100 acres, the average for Great Britain being 76.8, for England 82.4. Pigs in 1881 numbered 82,497.

The agriculture of Lincolnshire is only second to that of East Lothian, by which alone it is excelled in the use of fixed steam-engines upon its farmsteads. In the south part of the county small proprietors abound. According to the landowners' returns for 1879-73, the land in the county of Lincoln was divided among 80,497 owners, and its gross estimated rental was £3,173,826. Of the owners, 13,768, or more than 46 per cent., possessed less than 1 acre; the average value per acre was £1, 18s. 6d. There were four proprietors possessing over 10,000 acres each.—Earl of Yarborough, 55,272 acres, Lady Willoughby de Eresby, 24,698 acres; Henry Chapin, M.P., 28,870 acres, and Christopher Turner, 20,664 acres.

The following table gives a classification of holdings according to size as returned on the 26th June 1875 and the 4th June 1880:—

two each for the boroughs of Great Grimsby, Boston, Grantham, and Stamford. After the passing of that Act the county returned four members, and Grimsby lost one. In 1867 Stamford also lost a member, and the representation of the county, newly divided into Mid, North, and South Lincolnshire, was increased to six, each new division returning two members. Lincolnshire comprises one city, Lincoln (population 37,312), which is also a municipal and parliamentary borough, four other municipal and parliamentary boroughs—Boston (18,887), Grantham (17,845), Great Grimsby (45,378), Stamford, partly in Northampton (8996); and one municipal borough—Louth (16,680).

The county belongs to the midland arc. Besides the winter and summer assizes held at Lincoln, there are spring assizes held at the same place for Lincoln and North, and autumn assizes at Nottingham for North and Lincoln. Quarter sessions for the Parts of Lindsey are held at Lincoln and Spilsby, for the Parts of Kesteven at Boston and Stamford, for the Parts of Holland at Boston and Spalding. The county is divided into 177 vestmental county court districts, many of which coincide with the unions. For the convenience of rating there are eighteen poor law unions; five of these, however, include eighty parishes in the adjacent counties. Ecclesiastically the county, with that of Nottingham, forms the diocese of Lincoln, which is divided into the three archdeaconries of Lincoln, Stow, and Nottingham, the latter place giving title to a suffragan bishop without a see.

Education.—The educational resources of the county in 1881 embraced one theological and one training college, both at Lincoln, and fourteen endowed grammar schools at the following places:—Alford (founded 1565), Boston (1564), Bourn (1886), Caistor (1880), Donington (1701), Gainsborough (1689), Grantham (1528), Horncastle (1671), Lincoln (1588), Louth (1661), Moulton (1661), Spalding (1604), Spalding (1538), Spilsby (1660).

Population.—In 1881 the population of the county was 469,964 (266,014 males and 203,950 females); in 1871 it had been 419,245, and 486,809 in 1871. The figures are nine of the principal towns, in addition to the boroughs already given, are as follows:—Bourne (7121), Caistor (8798), Gainsborough (10,084), Glandford Bridge (3107), Horncastle (6190), Horncastle (4814), Spalding (4067), Spalding (5260), and Spilsby (7032).

History and Antiquities.—It is highly probable that the territory now forming Lincolnshire was first settled by a tribe of the Belgæ, who, however, at the time of the invasion by Cæsar, had become a mixed race with the real Britons. This territory was unaffected by Cæsar's first invasion, and even after the reduction of Britain by Claudius the Fenland remained intact. The county was conquered about 70 A.D., and formed part of the province of Flavia Cesariensis. The tribes which occupied Lincolnshire, according to Ptolemy, were the Coritani, who had Lindum and Rata (Leicester) for their towns. The date of the introduction of Christianity is uncertain, but we learn from Bede that in the year 626, St. Augustine of Cologne, Lindisfarne, which has been mistaken for London, attended the council of Arles (314). Under the Saxon kingdom of Mercia, Lindsey, which probably extended nearly or quite over the modern county of Lincoln, appears to have been a *seigniorial* state. Under Edwin of Northumbria, the conqueror of Mercia, Christianity was reintroduced by Paulinus of

York, and Bede tells us that Eadmund, the governor of Lincoln, was, with his household, among the first converted (628).

Early in 870 the Danes or Northmen landed at Humbleton near Gimsby, and ravaged Lindsey and the famous monastery of Haddesay on the Witham. Lincolnshire passed peacefully into the hands of the Danes about 877, and was included within the boundary of the "Danelage" of Danish jurisdiction as settled by the treaty of 878. Probably the greatest changes consequent upon the Danish invasion are, first, the supplanting of the Anglo-Saxon names of places by those of the Danish termination ending in *by*, which are numerous, and the substitution of the waperlake for the earlier division of the hundred, the ancient British laws and those of the Danes were otherwise not dissimilar. In time the two populations became amalgamated and came under the dominion of the Anglo-Saxon crown. The subsequent history of the county under the Normans is associated more or less with the city of Lincoln. In the civil war between Stephen and the empress Matilda a battle was fought near Lincoln in 1141. In 1174 the Isle of Axholme was the scene of the struggle between Roger de Mowbray, one of the adherents of Prince Henry, and the forces sent against him by his father Henry II. The issue was decided by the Lincolnshire men in favour of the king. In 1215 occurred King John's march across the county, when he lost all his baggage and jewels in the Fossebyke Wash on his way to Swineshead Abbey. In the reign of Edward IV Sir Robert Welles, at the head of 30,000 Lincolnshire men was defeated at Losecoat Field near Stamford, March 1470. At the suppression of the monasteries a rebellion broke out at Louth headed by Makenot, the last prior of the abbey of Balgates Oxney, October 1536. The prior was hanged, and the shrine for the tomb of the king to King Henry VIII was designated in a state paper as "one of the most brave and bestial of the whole realm." During the civil wars the county was the scene of numerous contests, the most famous of which was the battle at Gantham in 1648, won by Cromwell over the royalists. The advantage that was taken by the Femmen to destroy the efforts made to detain and enclose the remaining lands of Lincolnshire during this stormy period has been already noticed. Riots broke out at intervals, and were continued down to the middle of the 18th century.

Remains of British camps are found at Brixton, Torkington, Houghall, Rereby, and Well. Traces of Roman camps are found at Aldborough, Coston, Gainsborough, Geddely Hill near Holford, Holford, Holford, Holford, Holford, Holford, and York. The Roman roads are nearly perfect.—Eamne Street, on the east side of the Cliff hills, and the Fosseway running south-west from Lincoln. The crown of these remains is without doubt the famous Roman arch called the Newport Gate at Lincoln. Associated remains have been found at Denton, Holford, Lincoln, Scampton, and Winterton. Coins of the emperors Nero, Vespasian, and Julian have been found at Lincoln and Ancaster, and two Roman altars to the west of Stow.

There are remains of feudal castles at Boston, Lincoln, Sheaford, Somerton, Zettershall, and Torksey. The seats worthy of note (chiefly moated) are Appleby Hall, Aswarby Hall, Belton House, Blankney Hall, Brocklesby, Bulby House, Burghley House (near Stamford), Burton Hall, Casewick House, Denton Hall, Denton Hall, Hacketon Hall, Havenholme Priory, Lea Hall, Leadham House, Manby Hall, Newton House, Notton Hall, Romanby Hall, Notton Place, Notton Hall, Raby Grove, Somersby Park, Stourton, Syston Park, Thonock House, Tharby Hall, Uffington, and Willingham by Stow.

At the time of the suppression of the monasteries in the reign of Henry VIII. there were upwards of one hundred religious houses, and among the most famous of these some of the finest abbeys held by the Benedictines. The Gilbertines were a purely English order which took its rise in Lincolnshire, the canons following the Austin rule, the nuns and lay brothers that of the Cistercians. They generally lived in separate houses, but formed a community having a common church in which the services were divided by a longitudinal wall. These houses were at Avingham, Cister, Holland House, Lincoln, before the gate of which was erected the chief Eleanor Cross, Newstead in Lindsey, Somerby, the chief house of the order, founded by St Gilbert of Gant in 1139, Stamford (a college for students), and Welles. There were numerous of the order at Havenholme, Nun Ormsby, and Tuxford.

The following are a few of the most famous abbeys: (1) Balgates Oxney (Premonstratensian), founded 1164, for fourteen canons. The tower, decorated, with ascending piers with windows, and the east wall of the south wing remain. (2) The Benedictine Michel Abbey of Crowland founded 716, refounded in 948. The foundations of the new church in 1114 were laid on massive piles of oak. Part of the west front was repaired in 1255-81, with beautiful Early English sculpture of the legend of St Guthlac and saints, this, with the Perpendicular north-west tower, 1460-70, remain. (3) Swineshead Abbey (Cistercian), colonised from Furness in 1184 by eleven monks. (4) Thornton-upon-Humber Abbey (Black Canons), founded in 1189. There remain a fragment of the

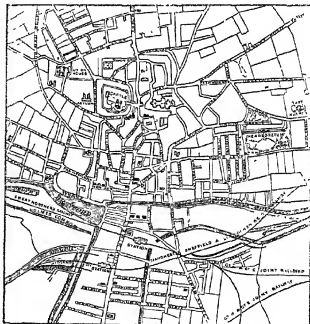

south wing of the transept, two sides of the decagonal chapter-house (1262), and the beautiful west gate-house, Early Perpendicular (1389-83), with an oval window on the east.

The general beauty of the parish churches of Lincolnshire is proverbial, but it is incorrect to suppose that they are equally good in every part of the county. In the Parts of Lindsey, though there are some of considerable beauty and interest, the churches can scarcely be considered above the average, several though small and mean present more or less features, particularly the well-known tower of St Peter, Barton-on-Humber, supposed to be of the Saxon period, and those of Gwile, Houghall, and Stow. Those of Gimsby and Wainfleet are a gem.

In the Parts of Kesteven the churches are not only elegant but well finished, built of excellent stone which abounds at Ancaster and near Stenford. The church of St Andrew Heckington is the best example of Middle Perpendicular architecture in the county, it is famed for its Easter sepulchre and fine sedilia. The largest and finest church in this division is doubtless that of St Wulfstan at Gantham, 200 by 87 feet, with three collateral naves, and steeple, 271 feet high, of the 11th century.

It is principally in the Parts of Holland that we are to look for the best churches in the county, they are not to be equalled by those of any other district in the kingdom, which is the more remarkable as the district is composed wholly of marsh land, and is without stone of any kind. It is highly probable that the churches of the south part of this district owe their origin to the munificence of the abbots of Crowland and Spalding. The earliest specimen of Norman architecture is that of Long Sutton, which has been called the counterpart of Christ Church, Oxford. St Mary and Nicholas at Spalding, 157 feet by 85, has the uncommon feature of a double aisle on each side of the nave, as well as a transept. The glory of the division of Holland is beyond question the church of St Botolph, Boston.

LINCOLN, the capital of the county of that name, as a city and county in itself, and is also a municipal and parliamentary borough. It is picturesquely situated on the summit and south slope of the limestone ridge of the Cliff range of hills which rises from the north bank of the river Witham, at its confluence with the Foss Dyke, to an altitude of 200 feet above the banks of the river. It is 132 miles north-west from London by road, and 138 miles by rail, 53° 15' N lat, 33° W long.

Plan of Lincoln

Lincoln is one of the most ancient and interesting cities in England. The ancient British town occupied the crown of the hill beyond the Newport or North Gate of the subsequent Roman town, the ancient earthworks and ditches of which are nearly continuous with the present boundaries of the parish of St John. The Roman town consisted of two parallelograms of unequal length, the first of which extended west from the Newport gate to a point

a little west of the castle keep. The second parallelogram extended due south from this point down the hill towards the Witham as far as Newland, and thence in a direction due east as far as Broad Street. Returning thence due north, it joined the south-east corner of the first and oldest parallelogram in what was afterwards known as the Minster yard, and terminated its east side upon its junction with the north wall in a line with the Newport gate. This is the oldest part of the town, and is named "above hill." After the departure of the Romans, the city walls were extended still further in a south direction across the Witham as far as the great bar gate, the south entrance to the High Street of the city; the junction of these walls with the later Roman one was effected immediately behind Broad Street. These three divisions comprise the boundaries of the municipal and parliamentary boroughs, which are enterminous. The "above hill" portion of the city is not well built, but consists of narrow irregular streets, some of which are too steep to admit of being ascended by carriages. The south portion, which is named "below hill," is much more commodious, and contains the principal shops and inns, with many elegant buildings and private residences. Here also are the Great Northern and Midland Railway stations.

The glory of Lincoln is its noble minster. As a study to the architect and antiquary this stands unrivalled, not only as the earliest purely Gothic building in Europe, but as containing within its compass every variety of style from the simple massive Norman of the west front, to the Late Decorated of the east portion. The building material is the colts and calcareous stone of Lincoln Heath and Haydock, which has the peculiarity of becoming hardened on the surface when tooled. In former days the cathedral had three spires, all of wood or leaded timber. The spire on the central tower was blown down in 1547. Those on the two western towers, 101 feet high, were removed in 1808; good representations of them will be found in the well-known views by Hollar and Buck. The ground plan of the first church, adopted from that of Rouen, was laid by Bishop Remigius in 1088, and the church was consecrated four days after his death, May 6, 1092; the central west front and the font are of this period. The approximate dates of the remaining portions of the fabric may be assigned as follows:—the three west portals and the Norman portion of the west towers above the screen to the top of the third story, about 1148; the nave, its aisles and the north and south chapels of the west end, completed 1220; the Early English portion of the west front, and the upper parts of the north and south wings, with pinnacles, turrets, 1225; the west porch of the main transept, 1250; the crossing, and lower part of the central tower, 1335; the upper part, 1307; the west door of the choir aisles, 1240. The south porch of the presbytery dates 1256. The east window, the finest of its style in England, 57 by 34 feet, dates 1358-55. The choir screens date 1280, the Easter sepulchre 1290. The gables and upper parts of the main transept, the parapets of the south side of the nave, south wing, and west front, and the screen in the south aisle, all date from 1335. The upper parts of the west towers date from 1355; their upper stories, the west windows and parapet of the galilee porch, and the chapel screens in the transept, 1450. The vaulted lantern of the central tower is 127 feet above the floor. The main transept has two fine rose windows; the one on the north called the Dean's Eye is 30 feet in diameter. The Bishop's Eye to the south is very fine Decorated (c. 1350). The roof screen is mainly a 1540.¹ The other buildings in

the close that call for notice are the chapter-house of ten sides, 60 feet diameter, 42 feet high, with a fine vestibule of the same height built in 1225, and the library, 104 by 17 feet, which contains a little museum. Among the most famous bishops were St. Hugh, who died 1200, Grosseteste, died 1253; Flemming, died 1431, founder of Lincoln College, Oxford, Smith, died 1521, founder of Brasenose, Oxford, Wake, and Gibson. Every stall has produced a prelate or cardinal; among those who have been cardinal members may be named Walter Mapes, Henry of Huntingdon, Polydore Vergil, W. Grocy, W. Outram, George Herbert, S. Pegg, V. Pegh, Cartwright, inventor of the power-loom, and O. Manning the topographer. Lincoln, the enormous diocese of which in early times extended from the Thames to the Humber, was one of the thirteen cathedrals of the old foundation served by secular canons.

History.—The name of Lincoln is a hybrid of Celtic and Latin. It appears in the Bavarian geographer in the form *Landina Colonia*, and in Bede as *Land-colina*. *Landum* is purely Celtic, and exactly describes the early British settlement as the "hill fort by the pool." *Landum Colonic* was founded on the site of what is now the castle and cathedral, about 100 A. D. It was besieged by Saxons in 514, and became one of the chief cities of Mercia. After being frequently ravaged by the Danes, Lincoln was recovered by Edmund I. in 1016. Lincoln Castle was built by William I. in 1066, which occasioned the removal of one hundred and sixty-six houses. Great and destructive fires occurred in 1110, 1128, and 1141. King Stephen besieged the emperor Matilda in the castle in 1140. Henry II. was crowned there in the following year, as was King Stephen at Christmas 1147. David, king of Scots, did homage to King John, 1201. Lincoln was captured by King John in 1216, and invested by the barons in 1217. The battle of Lincoln Fair took place in 1218. The city was sacked in 1260. John of Gaunt, earl of Lincoln, married there in 1396 Lady Swinford, Chaucer's sister-in-law; in virtue of his title he held the castle, but built himself a summer house in the lower part of the city. A parliament of Henry VI. met at Lincoln in 1456. The town was stormed by Earl Manchester on behalf of the Parliament in 1544.

Antiquities.—One of the most perfect specimens of genuine Roman architecture in England is the Newport or North Gate of Lincoln. It is sunk fully 11 feet below the present level of the street, and has two smaller arches on each side, the one to the west being concealed by an adjacent house. The Roman Ermine Street passes through this gate, and runs north from it for 11 or 12 miles as straight as an arrow. Many Roman coins, &c., have been found in the immediate vicinity of the gate. The other gates within the city worthy of notice are the Exchange Gate, a fine specimen of 13th century work, one of the bases of the north arch having upon it a carved representation of the crucifixion; Pottingate and Stonebow at the top of High Street, over which is the guildhall. The castle shows traces of Norman work, the foundations of which consisted of massive beams of wood and grouting. The hall of the old episcopal palace is 50 feet by 60 wide, and had two rows of grey marble pillars. The modern palace is at Risholme, 3 miles north of Lincoln. In the cloister garden are preserved a tessellated pavement and the sepulchral slab of a Roman soldier, the splendidly carved stone coffin lid of Bishop Remigius found there has recently been removed to the cathedral. The ancient conduits of St. Mary le Wigford, picturesque Gethin, and "the Greyfriars' goodly conduit" in the High Street, may also be noticed. The St. Mary's Guild near St. Peter's at Gowts is a fine specimen of Norman architecture, another fine relic of the domestic architecture of the period is the 3rd Henry's House, the windings of which are identical with those of the west portals of the cathedral (c. 1148). Near this is Dunstall, where the little Lincoln boy afterwards known as Little St. Hugh was crucified by Jews in August 1255. There were formerly three small prisons, five friaries, and four hospitals in or near Lincoln. The representatives of friaries over prisons of monks is explained by the fact that the cathedral was served by secular canons. The famous Bishop Grosseteste was the devoted patron of the friars, particularly the Franciscans, who were always in their day the town missionaries. There were fifty-two churches in the city before the Reformation, all the masses of which are preserved. Fourteen remain or have been rebuilt. There are fifteen benefices in the city, consisting of three rectories and twelve vicarages. There are fourteen Nonconformist places of worship.

¹ The dimensions of the cathedral internally are nave, 252 x 79-3 x 80 feet; choir, 158 x 82 x 73 feet; angle choir, which includes presbytery and lady chapel, 156 x 44 x 73 feet; main tran-

sept, 220 x 68 x 74 feet; choir transept, 156 x 44 x 73 feet. Externally the west front is 178 feet broad by 130 feet; the west towers are 206 feet high; the central tower, from which comes the town Great Tom of Lincoln (6 tone 8 cws.), is 262 feet high.

The charities comprise the new county hospital, general dispensary, lunatic asylum, penitentiary, home, and institute for nurses. The educational institutions comprise a theological college (formerly old county hospital), grammar school (formerly Grey-11108), blue coat school, training college for mistresses (Newport), St Martin's parochial schools, British schools (in Newland), Wesleyan school, and a school of art. Of other institutions may be named the Lincolnshire agricultural society, permanent library, mechanics' institute, county newsroom (above hill), city newsroom, and choral society. The remaining public buildings are the new corn exchange and masonic hall, county assembly-room and theatre in High Street. The public park is near the cattle market, and the racecourse beyond Newland. Population in 1811, 7000; in 1871, 26,768; in 1881, 37,612.

For the county and city of Lincoln see Wm. White, *History of Lincolnshire*, 1872; Sir C. H. J. Anderson, *Lincoln Pocket Guide*, 1880; J. P. Farnthorpe, *Geography of Lincolnshire*, 1872; Fred W. Wright, *Early English Church History*, 1876; Mr Wm. Dugdale, *Lincolnshire Antiquary*, 1675-82; J. Gough, *Parishes in Europe*, 1841; R. H. Miller and S. B. J. E. Smith, *The Fenland Past and Present*, 1879; Rev M. C. Wilcock, *Memoirs of Lincoln, 1866 and English Minutes*, 1879, 2 vols. (C. H. C.)

LINCOLN, a city of the United States, capital of Logan county, Illinois, is situated near Salt Creek, at the junction of three railways, 145 miles south-west of Chicago. It has fifteen churches, three banks, a high school, a telephone exchange, a coal-mine, two foundries, three flour-mills, five newspapers, and several grain elevators. It is the seat of Lincoln university (Cumberland Presbyterian) and of the State asylum for feeble-minded youth. A portion of the town dates from 1835, but the newer part was named in honour of Abraham Lincoln, and was incorporated in 1853. Population in 1880, 5639.

LINCOLN, a city of the United States, county seat of Lancaster county, Nebraska, and capital of the State. It is pleasantly situated about 50 miles west of the Missouri river, at the junction of several railroads, in the midst of a highly fertile and healthful region of undulating prairie, and near rich salt springs. Lincoln is the seat of the following State institutions—university, State prison, insane asylum, and home for the friendless. The prison and the asylum grounds, occupying several hundred acres, are 3 miles from the centre of the city, and 2 miles from each other. The United States Government has lately completed, at a cost of \$200,000, a massive building for collection of revenues, United States courts, and post-office. With its broad streets, its public park, and the State House and other grounds, the healthful ventilation of Lincoln is amply provided for. It has three daily papers, four banks, one of the largest printing and publishing houses west of the Mississippi, and several prosperous wholesale stores. Although but thirteen years old, it has a population (1880) of 15,003.

ABRAHAM LINCOLN

Copyright, 1882, by John G. Nicolay.

ABRAHAM LINCOLN (1809-1865), sixteenth president of the United States of America, was born in Hardin county, Kentucky, on February 12, 1809. His father, Thomas Lincoln, and his mother, Nancy Hanks, were both natives of Virginia, as was also his paternal grandfather, whose ancestors came from Berks county, Pennsylvania. When Lincoln was eight years of age his father moved to Indiana, in what is now Spencer county. The region was still a wilderness, and the boy grew up in pioneer life, dwelling in a rude log-cabin, and knowing but the primitive manners, conversation, and ambitions of sparsely settled backwood neighbourhoods. Schools were rare, and teachers only qualified to impart the merest rudiments of instruction. "Of course when I came of age I did not know much," wrote the future president; "still somehow I could read, write, and cipher to the rule of three, but that was all. I have not been to school since. The little advance I now have upon this store of education I have picked up from time to time under the pressure of necessity." In 1818

his mother died, and his father a year afterwards married again. When nineteen years of age Lincoln made a journey as a hired hand on a flatboat to New Orleans. In 1830 his father emigrated to Macon county, Illinois, and Lincoln aided in building the cabin, clearing a field, and splitting rails to fence it. The locality proved unhealthy, and general sickness made them resolve to abandon it. Being now twenty-one years of age, Lincoln hired himself to one Offutt, in Sangamon county, assisting him to build a flatboat and float it down the Sangamon, Illinois, and Mississippi rivers to New Orleans. Afterwards Offutt made him clerk of his country store at New Salem, this gave him moments of leisure to begin self-education. He borrowed a grammar and other books, and sought explanations from the village schoolmaster. Next year the Black Hawk Indian war broke out; Lincoln volunteered in one of the Sangamon county companies, and was elected captain. He was already a candidate for the Illinois legislature when this occurred; his printed address "To the people of Sangamon county" bears date March 9, 1832, and betokens talent and education far beyond mere ability to "read, write, and cipher." The Black Hawk campaign lasted about three months; Lincoln shared the hardships of camp and march, but was in no battle. He was defeated for the legislature that summer, being yet a comparative stranger in the county, but received a flattering majority in his own election precinct, where also, a little later, local friendship, disregarding politics, procured his appointment as postmaster of New Salem. The purchase and failure of a small country store having burdened him with debt, the county surveyor of Sangamon opportunely offered to make him one of his deputies. He qualified himself by study in all haste, and entered upon the practical duties of surveying farm lines, roads, and town sites. "This," to use his own words, "procured bread, and kept body and soul together."

The year 1834 had now arrived, and Lincoln was chosen one of the members of the Illinois legislature. He was re-elected successively in 1836, 1838, and 1840, after which he declined further nomination. At the two latter terms he received the complimentary vote of his party friends for speaker, they being in the minority. During the canvass of 1834 his political friend and colleague John T. Stuart, a lawyer in full practice, strongly encouraged him to study law, and lent him text-books to begin his reading. Lincoln followed his advice, and, working diligently, was admitted to the bar in the autumn of 1836. On April 15, 1837, he quitted New Salem, and removed to Springfield, which was then the county seat, but soon after became the capital of the State, to begin practice in partnership with his friend Stuart. His legislative experience was still further enlarged by his service of one term as representative to the Congress of the United States, to which he was elected in August 1846. He had become an eloquent and influential public speaker, and in several campaigns was on his party ticket as Whig candidate for presidential elector. Though to some extent still mingling in politics, Lincoln now for a period of about five years devoted himself more exclusively to the study and practice of law, his repeated successes drawing him into the most important cases.

In 1854 began the great slavery agitation by the repeal of the slavery prohibition of 1820, called the Missouri Compromise. Aroused to new activity by what he regarded a gross breach of political faith, Lincoln entered upon public discussions with an earnestness and force that by common consent gave him leadership of the opposition in Illinois, which that year elected a majority of the legislature. Thus would have secured his election to the United States senate, in the winter of 1854, to succeed Shields, &

Democrat, but four opposition members, of Democratic antecedents, refused to vote for Lincoln, who was yet called a Whig, and by their persistence compelled the election of Trumbull. The Republican party of Illinois was formally organized in 1856; the campaign resulted substantially in a drawn battle, the Democrats gaining a majority in the State for president, while the Republicans elected the governor and State officers. In 1858 the senatorial term of Douglas, author of the repeal of the Missouri compromise, was expiring, and he sought reelection. Lincoln, who had four years before successfully met him in public debate, was now by unanimous resolution of the Republican State convention designated as his rival and opponent. Yielding to the wish of his party friends, Lincoln challenged Douglas to a joint public discussion. The antagonists met in debate at seven designated points in the State, while they also separately addressed audiences in nearly every one of the hundred counties. At the November election the Republicans received a majority in the popular vote, but the Democrats, through a favourable apportionment of representative districts, secured a majority of the legislature, which re-elected Douglas. This remarkable campaign excited the closest attention from every part of the Union. Lincoln, addressing the convention which nominated him, June 16, 1858, opened the discussion with the following bold prophecy:—

"A house divided against itself cannot stand. I believe the Government cannot endure permanently half slave and half free. I do not expect the Union to be dissolved—I do not expect the house to fall—but I do expect it will cease to be divided. It will become all one thing or all the other. Either the opponents of slavery will arrest the further spread of it, and place it where the public mind shall rest in the belief that it is in course of ultimate extinction; or its advocates will push it forward, till it shall become alike lawful in all the States, old as well as new—North as well as South."

Lincoln's speeches in this campaign won him a national fame, which was greatly increased by several made in Ohio the following year, and especially by his Cooper Institute address in New York city, February 27, 1860. More than any contemporary statesman he had in the long six years' agitation insisted that, transcending the technical point of constitutional authority, or the problem of public policy, the deeper question of human right and wrong lay at the bottom of the slavery controversy.

The Republican national convention, which made "No Extension of Slavery" its principal tenet, met at Chicago, May 16, 1860. Seward was the leading candidate, but the more conservative delegates opposed him as being too radical, and uniting their forces nominated Lincoln, who was elected president of the United States after an unusually animated political campaign, November 6, 1860,¹ and inaugurated at Washington, March 4, 1861. Meanwhile a formidable movement, begun by South Carolina a month before the November election, and based on the slavery agitation, had carried the slave States South Carolina, Georgia, Alabama, Florida, Mississippi, Louisiana, and Texas into secession. A provisional government under the designation "The Confederate States of America," with Jefferson Davis as president, was organized by the seceding States, who seized by force nearly all the forts, arsenals, and public buildings within their limits. Great division of sentiment existed in the North, whether in this emergency acquiescence or coercion was the preferable policy. Lincoln's inaugural address declared the Union perpetual and acts of secession void, and announced the determination of the Government to defend its autho-

riety, and to hold forts and places yet in its possession. On the other hand, he disclaimed any intention to invade, subjugate, or oppress the seceding States. "You can have no conflict," he said, "without being yourselves the aggressors." Fort Sumter in Charleston harbour had been besieged by the secessionists since January, and, it being now on the point of surrender through starvation, Lincoln sent the besiegers official notice on April 8 that a fleet was on its way to carry provisions to the fort, but that he would not attempt to reinforce it unless the effort were resisted. The Confederates, however, immediately ordered its reduction, and after a thirty-four hours' bombardment the garrison capitulated, April 13, 1861.

With civil war thus provoked, Lincoln on April 15th by proclamation called 75,000 three months' militia under arms, and on May 4th ordered the further enlistment of 64,748 soldiers and 18,000 seamen for three years' service. He instituted a blockade of the Southern ports, took effective steps to extemporize a navy, convened Congress in special session, and asked for legislation and authority to make the war "short, sharp, and decisive." The country responded with enthusiasm to his summons and suggestions, and the South on its side was not less active. The Sumter bombardment rapidly developed and increased the limits of insurrection. Four additional slave States drifted into secession, the Unionists maintained ascendancy in Maryland, Kentucky, and Missouri, and succeeded in dividing Virginia. Minor engagements soon took place between the opposing forces; and on July 21, 1861, the first important battle was fought at Bull Run, and resulted in the defeat and panic of the Unionists.

The slavery question presented vexatious difficulties in conducting the war. Acute observers could not fail to note that its gigantic agencies were beginning to work in the direction of practical abolition. Congress in August 1861 passed an Act confiscating rights of slaveowners to slaves employed in hostile service against the Union. On August 31st General Fremont by military order declared martial law and confiscation against active enemies, with freedom to their slaves, in the State of Missouri. Believing that under existing conditions such a step was both detrimental in present policy and unauthorized in law, President Lincoln directed him to modify the order to make it conform to the Confiscation Act of Congress. Strong political factions were instantly formed for and against military emancipation, and the Government was hotly beset by antagonistic counsel. The Unionists of the border slave States were greatly alarmed, but Lincoln by his moderate conservatism held them to the military support of the Government. Meanwhile he sagaciously prepared the way for the supreme act of statesmanship which the gathering national crisis already dimly foreshadowed. On March 6, 1862, he sent a special message to Congress recommending the passage of a resolution offering pecuniary aid from the general Government to induce States to adopt gradual abolishment of slavery. Promptly passed by Congress, the resolution produced no immediate result except in its influence on public opinion. A practical step, however, soon followed. In April Congress passed and the president approved an Act emancipating the slaves in the District of Columbia, with compensation to owners—a measure which Lincoln had proposed when in Congress in 1849. Meanwhile slaves of loyal masters were constantly escaping to military camps. Some commanders excluded them altogether; others surrendered them on demand; while still others sheltered and protected them against their owners. Lincoln tolerated this latitude as falling properly within the military discretion pertaining to local army operations. A new case, however, soon demanded his official interference. On the 9th of May 1862 General

¹ The popular vote cast for electors stood—Lincoln, 1,866,462; Douglas, 1,876,157; Breckinridge, 847,988; Bell, 599,651. The official vote cast by the electors on December 5, 1860, and counted and declared by Congress on February 18, 1861, was—Lincoln, 180, Breckinridge, 72; Bell, 39; Douglas, 12.

Hunter, commanding in the limited areas gained along the southern coast, issued a short order declaring his department under martial law, and adding—"Slavery and martial law in a free country are altogether incompatible. The persons in these three States—Georgia, Florida, and South Carolina—hitherto held as slaves are, therefore, declared for ever free." As soon as this order, by the slow method of communication by sea, reached the newspapers, Lincoln (May 19) published a proclamation declaring it void; adding further, "Whether it be competent for me as commander-in-chief of the army and navy to declare the slaves of any State or States free, and whether at any time or in any case it shall have become a necessity indispensable to the maintenance of the Government to exercise such supposed power, are questions which under my responsibility I reserve to myself, and which I cannot feel justified in leaving to the decision of commanders in the field. These are totally different questions from those of police regulations in armies or camps." But in the same proclamation Lincoln recalled to the public his own proposal and the assent of Congress to compensate States which would adopt voluntary and gradual abolishment. "To the people of these States now," he added, "I most earnestly appeal. I do not argue. I beseech you to make the argument for yourselves. You cannot, if you would, be blind to the signs of the times." Meanwhile the anti-slavery sentiment of the North constantly increased. During June Congress by express Act prohibited the existence of slavery in all territories outside of States. On July 12th the president called the representatives of the border slave States to the executive mansion, and once more urged upon them his proposal of compensated emancipation. "If the war continues long," he said, "as it must if the object be not sooner attained, the institution in your States will be extinguished by mere friction and abrasion—by the mere incidents of the war. It will be gone, and you will have nothing valuable in lieu of it." While Lincoln's appeal brought the border States to no practical decision, it served to prepare public opinion for his final act. During the month of July his own mind reached the virtual determination to give slavery its *coup de grace*, and he wrote and submitted to his cabinet the draft of an emancipation proclamation substantially as afterward issued. Serious military reverses constrained him for the present to withhold it, while on the other hand they served to increase the pressure upon him from anti-slavery men. Horace Greeley having addressed a public letter to him complaining of "the policy you seem to be pursuing with regard to the slaves of the rebels," the president replied August 22, saying, "My paramount object is to save the Union, and not either to save or destroy slavery. If I could save the Union without freeing any slave, I would do it; if I could save it by freeing all the slaves, I would do it; and if I could do it by freeing some and leaving others alone, I would also do that." Thus still holding back violent reformers with one hand, and leading up halting conservatives with the other, he on September 13 replied among other things to an address from a delegation. "I do not want to issue a document that the whole world will see must necessarily be inoperative like the pope's bull against the comet. . . . I view this matter as a practical war measure, to be decided on according to the advantages or disadvantages it may offer to the suppression of the rebellion. . . . I have not decided against a proclamation of liberty to the slaves, but hold the matter under advisement."

The year 1862 had opened with important Union victories. Grant captured Forts Henry and Donelson, and won the battle of Shiloh. Burnside took possession of Roanoke island on the North Carolina coast. The

famous contest between the new ironclads "Monitor" and "Merrimack" ended in the Confederate vessel being beaten back, crippled, and ultimately destroyed. Farragut with a wooden fleet ran past the twin forts St Philip and Jackson, compelled the surrender of New Orleans, and gained control of the lower Mississippi. These successes extended from January to April. The succeeding three months brought disaster and discouragement to the Union army. McClellan's campaign against Richmond was made abortive by his bad generalship, and compelled the withdrawal of his army. Pope's army, advancing against the same city by another line, was beaten back upon Washington in defeat. The tide of war, however, once more turned in the defeat of Lee's invading army at South Mountain and Antietam in Maryland on the 14th and 17th of September, compelling him to retreat.

With public opinion thus ripened by alternate defeat and victory, President Lincoln on September 22, 1862, issued his preliminary proclamation of emancipation, giving notice that on the 1st of January 1863, "all persons held as slaves within any State or designated part of a State the people whereof shall then be in rebellion against the United States shall be then, thenceforward, and for ever free." In his message to Congress on the 1st of December following, he again urged his plan of gradual, compensated emancipation "as a means, not in exclusion of, but additional to, all others for restoring and preserving the national authority throughout the Union." On the 1st day of January 1863 the final proclamation of emancipation was duly issued, designating the States of Arkansas, Texas, Mississippi, Alabama, Florida, Georgia, South Carolina, North Carolina, and certain portions of Louisiana and Virginia, as "this day in rebellion against the United States," and proclaiming that, in virtue of his authority as commander-in-chief, and as a necessary war measure for suppressing rebellion, "I do order and declare that all persons held as slaves within said designated States and parts of States are and henceforward shall be free," and pledging the executive and military power of the Government to maintain such freedom. The legal validity of these proclamations was never pronounced upon by the national courts; but their decrees gradually enforced by the march of armies were soon recognized by public opinion to be practically irrevocable. Such dissatisfaction as they caused in the border slave States died out in the stress of war. The systematic enlistment of negroes and their incorporation into the army by regiments, hitherto only tried as exceptional experiments, were now pushed with vigour, and, being followed by several conspicuous instances of their gallantry on the battlefield, added another strong impulse to the sweeping change of popular sentiment. To put the finality of emancipation beyond all question, Lincoln in the winter session of 1863-64 strongly supported a movement in Congress to abolish slavery by constitutional amendment, but the necessary two-thirds vote of the House could not then be obtained. In his annual message of December 6, 1864, he urged the immediate passage of the measure. Congress now acted promptly: on January 31, 1865, that body by joint resolution proposed to the States the 13th amendment of the federal constitution, providing that "neither slavery nor involuntary servitude, except as a punishment for crime, whereof the party shall have been duly convicted, shall exist within the United States or any place subject to their jurisdiction." Before the end of that year twenty-seven out of the thirty-six States of the Union (being the required three-fourths) had ratified the amendment, and official proclamation made December 19, 1865, declared it duly adopted.

The foreign policy of President Lincoln, while subordinate in importance to the great questions of the civil war,

nevertheless presented several difficult and critical problems for his decision. Towards the close of 1861 the arrest by Captain Wilkes of two Confederate envoys proceeding to Europe in the British steamer "Trent" seriously threatened peace with England. Public opinion in America almost unanimously sustained the act; but Lincoln, convinced that the proceeding had been unlawful, promptly, upon the suggestion of England, ordered the liberation of the prisoners. A still broader foreign question grew out of Mexican affairs, when events culminating in the setting up of Maximilian of Austria as emperor under protection of French troops demanded the constant watchfulness of the United States. Lincoln's course was one of prudent moderation. France voluntarily declared that she sought in Mexico only to satisfy injuries done her and not to overthrow or establish local government or to appropriate territory. The United States Government replied that, relying on these assurances, it would maintain strict non-interference, at the same time openly avowing the general sympathy of its people with a Mexican republic, and that "their own safety and the cheerful destiny to which they aspire are intimately dependent on the continuance of free republican institutions throughout America." In the early part of 1863 the French Government proposed a mediation between the North and the South. This offer President Lincoln declined to consider, Seward replying for him that it would only be entering into diplomatic discussion with the rebels whether the authority of the Government should be renounced, and the country delivered over to dissension and anarchy.

The civil war gradually grew to dimensions beyond all expectation. By January 1863 the Union armies numbered near a million men, and were kept up to this strength till the end of the struggle. The Federal war debt eventually reached the sum of \$2,700,000,000. The fortunes of battle were somewhat fluctuating during the first half of 1863, but the beginning of July brought the Union forces decisive victories. The reduction of Vicksburg and Port Hudson, with other operations, restored complete control of the Mississippi, severing the Southern Confederacy. In the east Lee had the second time marched his army into Pennsylvania to suffer a disastrous defeat at Gettysburg, on July 1st to 3d, though he was able to withdraw his shattered forces south of the Potomac. At the dedication of this battlefield as a soldiers' cemetery in November, President Lincoln made the following oration, which has taken permanent place as a classic in American literature:—

"Four score and seven years ago our fathers brought forth on this continent a new nation conceived in liberty and dedicated to the proposition that all men are created equal. Now we are engaged in a great civil war testing whether that nation, or any nation so conceived and so dedicated, can long endure. We are met on a great battlefield of that war. We have come to dedicate a portion of that field as a final resting-place for those who here gave their lives that that nation might live. It is altogether fitting and proper that we should do this. But, in a larger sense, we cannot dedicate, we cannot consecrate, we cannot hallow this ground. The brave men, living and dead, who struggled here have consecrated it far above our poor power to add or detract. The world will little note nor long remember what we say here, but it can never forget what they did here. It is for us the living rather to be dedicated here to the unfinished work which they who fought here have thus far so nobly advanced. It is rather for us to be here dedicated to the great task remaining before us—that from these honored dead we take increased devotion to that cause for which they gave the last full measure of devotion—that we here highly resolve that these dead shall not have died in vain, that this nation under God shall have a new birth of freedom, and that government of the people, by the people, for the people, shall not perish from the earth."

In the unexpected prolongation of the war, volunteer enlistments became too slow to replenish the waste of armies, and in 1863 the Government was forced to resort

to a draft. The enforcement of the conscription created much opposition in various parts of the country, and led to a serious riot in the city of New York on July 13. President Lincoln executed the draft with all possible justice and forbearance, but refused every importunity to postpone it. It was made a special subject of criticism by the Democratic party of the North, which was now organizing itself on the basis of a discontinuance of the war, to endeavour to win the presidential election of the following year. Mr Vallandigham of Ohio, having made a violent public speech against the war and military proceedings, was arrested by General Burnside, tried by military commission, and sentenced to imprisonment; a writ of *habeas corpus* was refused, and the sentence was changed by the president to transportation beyond the military lines. By way of political defiance the Democrats of Ohio nominated Vallandigham for governor. Prominent Democrats and a committee of the Convention having appealed for his release, Lincoln wrote two long letters in reply discussing the constitutional question, and declaring that in his judgment the president as commander-in-chief in time of rebellion or invasion holds the power and responsibility of suspending the privilege of the writ of *habeas corpus*, but offering to release Vallandigham if the committee would sign a declaration that rebellion exists, that an army and navy are constitutional means to suppress it, and that each of them would use his personal power and influence to prosecute the war. This liberal offer and their refusal to accept it counteracted all the political capital they hoped to make out of the case; and public opinion was still more powerfully influenced in behalf of the president's action, by the pathos of the query which he propounded in one of his letters:—"Must I shoot the simple-minded soldier boy who deserts, while I must not touch a hair of a wily agitator who induces him to desert?" When the election took place in Ohio, Vallandigham was defeated by a majority of more than a hundred thousand.

Many unfounded rumours of a willingness on the part of the Confederate States to make peace were circulated from time to time to weaken the Union war spirit. To all such suggestions, up to the time of issuing his emancipation proclamation, Lincoln announced his readiness to stop fighting and grant amnesty, whenever they would submit to and maintain the national authority under the constitution of the United States. Certain agents in Canada having in 1864 intimated that they were empowered to treat for peace, Lincoln, through Greeley, tendered them safe conduct to Washington. They were by this forced to confess that they possessed no authority to negotiate. The president thereupon sent them, and made public, the following standing offer:—

"To whom it may concern

"Any proposition which embraces the restoration of peace, the integrity of the whole Union, and the abandonment of slavery, and which comes by and with an authority that can control the armies now at war against the United States, will be received and considered by the Executive Government of the United States, and will be met by liberal terms on substantial and collateral points, and the bearer or bearers thereof shall have safe conduct both ways.

"ABRAHAM LINCOLN."

"July 18, 1864."

A noteworthy conference on this question took place near the close of the civil war, when the strength of the rebellion was almost exhausted. F. P. Blair, senior, a personal friend of Jefferson Davis, acting solely on his own responsibility, was permitted to go from Washington to Richmond, where, after a private and unofficial interview, Davis in writing declared his willingness to enter a conference "to secure peace to the two countries." Report being duly made to President Lincoln, he wrote a note consenting to receive any agent sent informally "with

a view of securing peace to the people of our common country." Upon the basis of this latter proposition three Confederate commissioners finally came to Hampton Roads, where President Lincoln and Secretary Seward met them, and on February 3, 1865, an informal conference of four hours' duration was held. Private reports of the interview agree substantially in the statement that the Confederates proposed a cessation of the civil war, and postponement of its issues for future adjustment, while for the present the belligerents should unite in a campaign to expel the French from Mexico, and to enforce the Monroe doctrine. President Lincoln, however, declined the ensnaring alliance, and adhered to the instructions he had given Seward before deciding to personally accompany him. These formulated three indispensable conditions to adjustment:—first, the restoration of the national authority throughout all the States; second, no receding by the executive of the United States on the slavery question; third, no cessation of hostilities short of an end of the war, and the disbanding of all forces hostile to the Government. These terms the commissioners were not authorized to accept, and the interview ended without result.

As Lincoln's first presidential term of four years neared its end, the Democratic party gathered itself for a supreme effort to regain the ascendancy lost in 1860. The slow progress of the war, the severe sacrifice of life in campaign and battle, the enormous accumulation of public debt, arbitrary arrests and suspension of *habeas corpus*, the rigour of the draft, and the proclamation of military emancipation furnished ample subjects of bitter and vindictive campaign oratory. A partisan coterie which surrounded McClellan loudly charged the failure of his Richmond campaign to official interference in his plans. Vallandigham had returned to his home in defiance of his banishment beyond military lines, and was leniently suffered to remain. The aggressive spirit of the party, however, pushed it to a fatal extreme. The Democratic National Convention adopted (August 29, 1864) a resolution declaring the war a failure, and demanding a cessation of hostilities, it nominated McClellan for president, and instead of adjourning *sine die* as usual, remained organized, and subject to be convened at any time and place by the executive national committee. This threatening attitude, in conjunction with alarming indications of a conspiracy to resist the draft, had the effect to thoroughly consolidate the war party, which had on June 8 unanimously renominated Lincoln. At the election held November 8, 1864, Lincoln received 2,216,076 of the popular votes, and McClellan but 1,808,725, while of the presidential electors 212 voted for Lincoln and 21 for McClellan. Lincoln's second term of office began March 4, 1865.

While this political contest was going on the civil war was being brought to a decisive close. Grant, at the head of the army of the Potomac, followed Lee from before Washington to Richmond and Petersburg, and held him in siege to within a few days of final surrender. Sherman, commanding the bulk of the Union forces in the Mississippi valley, swept in a victorious march through the heart of the confederacy to Savannah on the coast, and thence northward to North Carolina. Lee evacuated Richmond April 2, and was overtaken by Grant and compelled to surrender his entire army April 9, 1865. Sherman pushed Johnston to a surrender April 26. This ended the war, the submission of scattering detachments following soon after.

Lincoln being at the time on a visit to the army, entered Richmond the day after its surrender. Returning to Washington, he made his last public address on the evening of April 11, devoted mainly to the question of reconstructing loyal governments in the conquered States. On the

evening of April 14 he attended Ford's theatre in Washington. While seated with his family and friends absorbed in the play, John Wilkes Booth, an actor, who with others had prepared a plot to assassinate the several heads of government, went into the little corridor leading to the upper stage-box, and secured it against ingress by a wooden bar. Then stealthily entering the box, he discharged a pistol at the head of the president from behind, the ball penetrating the brain. Brandishing a huge knife, with which he wounded Colonel Rathbone who attempted to hold him, the assassin rushed through the stage-box to the front and leaped down upon the stage, escaping behind the scenes and from the rear of the building, but was pursued, and twelve days afterwards shot in a barn where he had concealed himself. The wounded president was borne to a house across the street, where he breathed his last at 7 A.M., April 15, 1865.

In 1842 he had married Mary Todd, also of Kentucky, who bore him four children. Only one son, Robert T. Lincoln, survives, who is at this date (1882) secretary of war of the United States.

President Lincoln was of unusual stature, 6 feet 4 inches, and of spare but muscular build, he had been in youth remarkably strong and skilful in the athletic games of the frontier, where, however, his popularity and recognized impartiality often made him an umpire than a champion. He had regular and propensities features, dark complexion, broad high forehead, prominent cheek bones, grey deep-set eyes, and bushy black hair, turning to grey at the time of his death. Abstemious in his habits, he possessed great physical endurance. He was almost as tender-hearted as a woman. "I have not willingly planted a thorn in any man's bosom," he was able to say. His patience was mechanical. He had naturally a most cheerful and sunny temper, was highly social and sympathetic, loved pleasant conversation, wit, anecdote, and laughter. Beneath this, however, ran an undercurrent of sadness, he was occasionally subject to hours of deep aliveness and introspection that approached a condition of trance. In manner he was simple, direct, free of the least affectation, and entirely free from awkwardness, oddity, or eccentricity. His mental qualities were—a quick analytic perception, strong logical powers, a tenacious memory, a liberal estimate and tolerance of the opinions of others, ready intuition of human nature; and perhaps his most valuable faculty was rare ability to dress himself in all feeling or passion in weighing motives of persons or problems of state. His speech and diction were plain, terse, forcible. Relating anecdotes with appreciative humour and fascinating dramatic skill, he used them freely and effectively in conversation and argument. He loved manliness, truth, and justice. He despised all trickery and selfish greed. In arguments at the bar he was so far from his opponent that he frequently appeared to comede away his client's case. He was ever ready to take blame on himself and bestow praise on others. "I claim not to have controlled events," he said, "but confess plainly that events have controlled me." The Declaration of Independence was his political chart and inspiration. He acknowledged a universal equality of human rights. "Certainly the negro is not our equal in colour," he said, "perhaps not in many other respects; still, in the right to put into his mouth the bread that his own hands have earned, he is the equal of every other man white or black." He had unchanging faith in self-government. "The people," he said, "are the rightful masters of both congresses and courts, not to overthrow the constitution, but to overthrow the man who perverts this constitution." Yielding and accommodating in non-essentials, he was inflexibly firm in a principle or position deliberately taken. "Let us have faith that right makes might," he said, "and in that faith let us to the end struggle to our duty as we understand it." The emancipation proclamation once issued, he reiterated his purpose never to retract or modify it. "There have been men base enough," he said, "to promise to me to return to slavery our black warriors of Fort Hudson and Olustee, and thus win the respect of the masters they fought. Should I do so, I should deserve to be damned as time and eternity. Come what will, I will keep my faith with friend and foe." Benevolence and forgiveness were the very basis of his character; his world-wide humanity is aptly embodied in a phrase of his second inaugural:—"With malice toward none, with charity for all." His nature was deeply religious, but he belonged to no denomination; he had faith in the eternal justice and boundless mercy of Providence, and made the golden rule of Christ his practical creed. History must accord him a rare sagacity in guiding a great people through the perils of a mighty revolution, an admirable singleness of aim, a skilful discernment and courageous seizure of the golden moment to free

his nation from the incubus of slavery, faithful adherence to law and conscientious moderation in the use of power, a shining personal example of honesty and purity, and finally the possession of that subtle and indelible magnetism by which he subordinated and directed dangerously disturbed and perverted moral and political forces to the restoration of peace and constitutional authority to his country, and the gift of liberty to four millions of human beings. Architect of his own fortune, rising with every opportunity, mastering every emergency, fulfilling every duty, he not only proved himself pre-eminently the man for the hour, but the signal benefactor of posterity. A statesman, ruler, and liberator civilization will hold his name in perpetual honour. (J. G. N.)

LINDAU, a town in the government district of Swabia and Neuburg, Bavaria, and the central point of the transit trade between that country and Switzerland, is situated on two islands off the north-eastern shore of Lake Constance, in 47° 34' N. lat., 9° 43' E. long. The town is a terminus of the Voralberg Railway, and of the Munich-Lindau line of the Bavarian State Railway, and is connected with the mainland both by a wooden bridge and by a railway embankment of stone erected in 1853. There are Roman Catholic and Lutheran churches, a royal chateau, an old town-hall, classical, commercial, and industrial schools, and also manufactories for surgical and musical instruments, a fishery, and a fine harbour provided with a lighthouse and much visited by steamers from Constance and other places on the lake. Opposite the custom-house is a bronze statue of king Maximilian II., erected in 1856. The trade is chiefly in grain, fruit, wine, cherry-brandy, fish, cheese, and lard. In January 1882 the population was about 3350.

On the site which the town now occupies there is believed to have been formerly an ancient Roman camp, *Castrum Tiberi*. Authentic records of Lindau date back to the end of the 9th century. It was 1681 joined the Smallpox league, and in 1647 was unfortunately besieged by the Swedes. From 1726 to 1808 it was a free imperial town. In 1804 it passed to Austria, and in 1806 to Bavaria.

LINDLEY, JOHN (1799–1885), botanist, was born on February 6, 1799, at Catton near Norwich, where his father, George Lindley, author of *A Guide to the Orchard and Kitchen Garden*, owned a nursery garden. He was educated at Norwich grammar school, and early manifested a taste for the studies in which he afterwards gained distinction. His first publication, in 1819, a translation of the *Analyses du Fruit* of Richard, was followed in 1820 by an original *Monographia Rosarum*, with descriptions of new species, and drawings executed by himself, and in 1821 by *Monographia Digitalium*, and by "Observations on Pomaceae" contributed to the *Transactions of the Linnean Society*. Shortly afterwards he went to London, where he was engaged by London to write the descriptive portion of the *Encyclopædia of Plants*. In the course of his labours on this undertaking, which was completed in 1829, and of which the "botanical merits" are in the preface assigned by the editor to Lindley, he became thoroughly convinced of the superiority of the "natural" system of Jussieu, as distinguished from the "artificial" system of Linnaeus followed in the *Encyclopædia*; the conviction found expression in *A Synopsis of British Flora*, arranged according to the *Natural Order* (1829), and in *An Introduction to the Natural System of Botany* (1830). In 1829 Lindley, who since 1822 had been assistant secretary to the Horticultural Society, was appointed to the chair of botany in University College, London; he lectured also on botany from 1831 at the Royal Institution, and from 1836 at the Botanic Gardens, Chelsea. During his professorate of more than thirty years he wrote many scientific and popular works, besides contributing largely to the *Botanical Register*, of which he was editor for many years, and to the *Gardener's Chronicle*, in which he had charge of the horticultural department from 1841. He became a fellow of the Royal, Linnean, and Geological Societies, and had

the honour of being admitted to a large number of foreign scientific bodies. He resigned his chair in 1860, and died of apoplexy at Turnham Green on November 1, 1885.

Besides those already mentioned, the works of Lindley include *An Outline of the First Principles of Horticulture* (1832), *An Outline of the Structure and Physiology of Plants* (1838), *A Natural System of Botany* (1836), *The Florist's Guide of Great Britain* (the joint work of Lindley and Hutton, 1831–37), *Flora Medica* (1838), *The Vegetable Kingdom* (1846), *Theory of Horticulture* (2d ed., 1856), *Risks of Horticulture* (1859), *Decorative Botany* (1856), *Ladies' Botany*, a School Botany, the volume *Botany in the Library of Useful Knowledge*, and most of the botanical articles in the *Fanny Cyclopædia*. See BOTANY, vol. iv. p. 81.

LINDSEY, THORPHILUS (1723–1808), an English theological writer, was born in Middlewich, Cheshire, on June 20, 1723, was educated at the Leeds Free School, and in 1741 entered St John's College, Cambridge, of which, after graduating with distinction, he became a fellow in 1747. For some time he held a curacy in Spitalfields, London, and from 1754 to 1756 he travelled on the Continent in the capacity of tutor to the young duke of Northumberland. On his return he was presented to the living of Kirkby-Wisak in Yorkshire, and after exchanging it for that of Piddletown in Dorsetshire he in 1763 removed to Cattamk in Yorkshire. Meanwhile he had begun to entertain anti-Trinitarian views, and to be troubled in conscience about their inconsistency with the creed he had repeatedly subscribed; since 1769 the intimate friendship of Priestley had served to foster his scruples, and in 1771 he united with Archdeacon Blackburne (his father-in-law), Jebb, Wyvell, and Law in preparing a petition to parliament with the prayer that clergymen of the church, and graduates of the universities, might be relieved from the burden of subscribing to the thirty-nine articles, and "restored to their undoubted rights as Protestants of interpreting Scripture for themselves." After two hundred and fifty signatures to the document had, with six months of vast effort on Lindsey's part, been obtained, it was, in February 1772, rejected in the House of Commons by the majority of two hundred and seventeen to seventy-one, a adverse vote was repeated in the following year, and in the end of 1773, seeing no prospect of obtaining within the church the relief which his conscience demanded, Lindsey resigned his vicarage and took leave of a warmly attached congregation. In April 1774 he began to conduct a Unitarian service in a room in Essex Street, Strand, London; four years later he removed to a chapel built for him in the same street. Here he continued to labour till 1795, when he resigned his charge in favour of Disney, who like himself had left the established church, and had become his colleague. His active interest in the Unitarian movement continued, however, until his death, which took place on November 3, 1808.

Lindsey's chief work is *An Historical View of the State of the Unitarian Doctrine and Worship from the Reformation to our own Times*, 1783, in it he claims, amongst others, Barret, Tillotson, S. Clarke, Hoadly, and Sir L. Newton for the Unitarian view. His other publications, mostly occasional, include *Apology on Resigning the Vicarage of Cattamk* (1774), and *Sermon to the Apology* (1776); *The Book of Common Prayer reformed according to the plan of the late Dr Samuel Clarke*, 1774; *Dissertations on the Prophecy of St John's Gospel and on praying to Jesus Christ*, 1779; *Finalist's Protestation*, 1788; *Conversations upon Christian Holiness*, 1792; and *Conversations on the Divine Government, showing that everything is from God, and for good to all*, 1802. Two volumes of *Sermons*, with appropriate prayers annexed, were published posthumously in 1810; and a volume of *Memories*, by Thomas Belsham, appeared in 1812.

LINEN MANUFACTURES. Under this term are comprehended all yarns spun and fabrics woven from flax fibre. The cultivation and preparation of the fibre, and its treatment till it reaches the market as a commercial product, are dealt with under FLAX, vol. ix. p. 293.

From the earliest periods of human history till almost the close of the 18th century the linen manufacture was

one of the most extensive and widely disseminated of the domestic industries of European countries. The preparation and spinning of yarn gave occupation to women of all classes; and the operations of weaving employed large numbers of both sexes. The industry was most largely developed in Russia, Austria, Germany, Holland, Belgium, the northern provinces of France, and certain parts of England, in the north of Ireland, and throughout Scotland, and in these countries its importance was generally recognized by the enactment of special laws, having for their object the protection and extension of the trade. The inventions of Arkwright, Hargreaves, and Crompton in the latter part of the 18th century, benefiting as they did, almost exclusively, the art of cotton spinning, and the unparalleled development of that branch of textile manufactures, largely due to the ingenuity of these inventors, gave the linen trade as it then existed a fatal blow. Domestic spinning, and with it hand-loom weaving, immediately began to shrink; a large and most respectable section of the operative classes in western Europe found their employment dwindling away, and the wages they earned from their diminished labour insufficient to ward off starvation. The trade which had supported whole villages and provinces entirely disappeared, and the linen manufacture, in attenuated dimensions and changed conditions, took refuge in special localities, where it resisted, not unsuccessfully, the further assaults of cotton, and, with varying fortunes, rearranged its relations in the community of textile industries. The linen industries of the United Kingdom were the first to suffer from the aggression of cotton; more slowly the influence of the rival textile travelled across Continental countries; and even to the present day, in Russia, and in other regions remote from great commercial highways, the domestic manufacture of flanne holds its place almost as it has done from the earliest period. In 1810 Napoleon I., with a view partly to promote Continental linen industries, and partly to strike a blow at the great British manufacture of cotton, issued a proclamation offering a reward of one million francs to any inventor who should devise the best machinery for the spinning of flax yarn. Within a few weeks thereafter Philippe de Girard patented in France important inventions for flax spinning by both dry and wet methods. His inventions, however, did not receive the promised reward, and were indeed neglected in his native country. In 1815 he was invited by the Austrian Government to establish a spinning mill at Hirtenberg near Vienna, which was run with his machinery for a number of years, but ultimately it failed to prove a commercial success. In the meantime, however, English inventors, stimulated rather than daunted by the success of cotton machinery, had applied themselves to the task of adapting machines to the preparation and spinning of flax. The foundation of machine spinning of flax was laid by John Kendrew and Thomas Porthouse of Darlington, who, in 1787, secured a patent for "a mill or machine upon new principles for spinning yarn from hemp, tow, flax, or wool." These machines, imperfect as they were, attracted much notice, and were introduced in various localities both in England and Scotland into mills fitted specially for flax spinning. By innumerable successive improvements and modifications, the invention of Kendrew and Porthouse developed into the perfect system of machinery with which, at the present day, spinning-mills are furnished; but progress in adapting flax fibre for mechanical spinning, and linen yarn for weaving cloth by power-loom, was much slower than in the corresponding case of cotton.

The implements used in the preparation of linen yarn in ancient and modern times, down to the end of the 18th century, were of the most primitive and inexpensive

description. Till comparatively recent times, the sole spinning implements were the spindle and distaff. The spindle, which is the fundamental apparatus in all spinning machinery, was nothing more nor less than a round stick or rod of wood about 12 inches in length, tapering towards each extremity, and having at its upper end a notch or slit into which the yarn might be caught or fixed. In general, a ring or "whorl" of stone or clay was passed round the upper part of the spindle to give it momentum and steadiness when in rotation. The distaff, or rock, was a rather longer and stronger bar or stick, around one end of which, in a loose coil or ball, the fibrous material to be spun was wound. The other extremity of the distaff was carried under the left arm, or fixed in the girdle at the left side, so as to have the coil of flax in a convenient position for drawing out to yarn. A prepared end of yarn being fixed into the notch, the spinner, by a smart rolling motion of the spindle with the right hand against the right leg, threw it out from her, spinning in the air, while, with the left hand, she drew from the rock an additional supply of fibre which was formed into a uniform and equal strand with the right. The yarn being sufficiently twisted was released from the notch, wound around the lower part of the spindle, and again fixed in the notch at the point insufficiently twisted; and so the rotating, twisting, and drawing out operations went on till the spindle was full. So persistent is an ancient and primitive art of this description that to the present day, in remote districts of Scotland,—the country where machine spinning has attained its highest development,—spinning with rock and spindle is yet practised,¹ and, rude as these implements are, yarn of extraordinary delicacy, beauty, and tenacity has been spun by their agency. The first improvement on the primitive spindle was found in the construction of the hand-wheel, in which the spindle, mounted in a frame, was fixed horizontally, and rotated by a band passing round it and a large wheel, set in the same framework. Such a wheel became known in Europe about the middle of the 16th century, but it appears to have been in use for cotton spinning in the East from time immemorial. At a later date, which cannot be fixed, the treadle motion was attached to the spinning wheel, enabling the spinner to sit at work with both hands free, and the introduction of the two-handed or double-spindle wheel, with flyers or twisting arms on the spindles, completed the series of mechanical improvements effected on flax spinning till the end of the 18th century. The common use of the two-handed wheel throughout the rural districts of Ireland and Scotland is a matter still within the recollection of middle-aged people; but spinning wheels are now seldom seen.

The modern manufacture of linen divides itself into two branches, spinning and weaving, to which may be added the bleaching and various finishing processes, which, in the case of many linen textures, are laborious undertakings and important branches of industry.

Flax, when received into the mills, has to undergo a train of preparatory operations before it arrives at the stage of being twisted into yarn. The whole operations in yarn manufacture comprise (1) heckling, (2) preparing, and (3) spinning.

Heckling.—This first preparatory process consists not only in combing out, disentangling, and laying smooth and parallel the separate fibres, but also serves to split up and separate into their ultimate filaments the strands of fibre which, up to this point, have been agglutinated together. The heckling process was, until recent times, done by the hand; and it was one of fundamental importance, requiring the exercise of much dexterity and judgment. The

¹ See Dr Arthur Mitchell's *The Past in the Present*. Edinburgh, 1886.

broken, unravelled, and short fibres, which separate out in the heckling process, form tow, an article of much inferior value to the spinner, and the proportion of tow made in the process of hand-heckling varies according to the skill and knowledge of the heckler. A good deal of hand-heckling is still practised, especially in Irish and Continental factories, and it has not been found practicable, in any case, to entirely dispense with a rough preparation of the fibre by hand labour. In heckling by hand, the heckler strikes a handful or "stick" of rough flax, winds the top end round his hands, and then, spreading out the root end as broad and flat as possible, by a swinging motion dashes the fibre into the teeth or needles of the rougher or "ruffer" heckle. The rougher is a board plated with tin, and studded with spikes or teeth of steel about 7 inches in length, which taper to a fine sharp point. The heckler draws his stick several times through this tool, working gradually up from the roots to near his hand, till in his judgment the fibres at the root end are sufficiently combed out and smoothed. He then seizes the root end and similarly treats the top end of the stick. The sticks, as finished, are carefully piled up in a regular manner, keeping each handful separate for convenience of future treatment. The same process is again repeated on a similar tool, the teeth of which are 5 inches long, and much more closely studded together, and for the finer counts of yarn a third and a fourth heckle may be used, of still increasing fineness and closeness of teeth. In dealing with certain varieties of the fibre, for fine spinning especially, the flax is, after roughing, broken or cut into three lengths—the top, middle, and root ends. Of these the middle cut is most valuable, being uniform in length, strength, and quality. The root end is more woody and harsh, while the top, though fine in quality, is uneven and variable in strength. From some flax of extra length it is possible to take two short middle cuts, and, again, the fibre is occasionally only broken into two cuts according to the judgment and requirement of the manufacturer. Flax so prepared is known as "cut line" in contradistinction to "long line" flax, which is the fibre unbroken. The subsequent treatment of line, whether long or cut, does not present sufficient variation to require further reference to these distinctions.

In the case of heckling by machinery, the flax is first roughed and arranged in sticks, as above described under hand heckling. Considerable variations are presented in the construction of heckling machines, but the general principles of those now most commonly adopted, such as the machines of Combe, of Horner, or of Cotton, &c., are identical. These are known as vertical sheet heckling machines (fig. 1), their essential features being a set of endless leather bands or sheets *f, g* revolving over a pair of rollers *e, e* in a vertical direction. These sheets are crossed by iron bars, to which heckle stocks, furnished with teeth, are secured. The heckle stocks on each separate sheet are of one size and gauge, but each successive sheet in the length of the machine is furnished with stocks of increasing fineness, so that the heckling tool at the end where the flax is entered is the coarsest, while that to which the fibre is last submitted has the smallest and most closely set teeth. Thus the whole of the endless vertical revolving sheet presents a continuous series of heckle teeth, and the machines are furnished with a double set of such sheets revolving face to face, so close together that the pins of one set of sheets intersect those on the opposite stocks. Overhead, and exactly centred between these revolving sheets, is the head or holder channel *a*, from which the flax hangs down while it is undergoing the heckling process on both sides. The flax is fastened in a holder *b*, consisting of two heavy flat plates of iron, between which it is spread

and tightly screwed up. The holder is 11 inches in length, and the holder channel is fitted to contain a line of six, eight, or twelve such holders, according to the number of separate bands of heckling stocks in the machine. The head or holder channel has a falling and rising motor, by which it first presents the ends and gradually more and more of the length of the fibre to the heckle teeth, and, after dipping down the full length of the fibre exposed, it slowly rises and lifts the flax clear of the heckle stocks. By a reciprocal motion the whole of the holders are then moved forward one length, that at the last and finest set of stocks is thrown out, and place is made for filling in an additional holder at the beginning of the series. Thus with a six-tool heckle, or set of stocks, each holder full of flax from beginning to end descends

FIG. 1.—Section of Combe's Heckling Machine.

into and pass from the heckle teeth six times in travelling from end to end of the machine. The root ends being thus first heckled, the holders are shot back along an inclined plane, the iron plates unclamped, the flax reversed, and the top ends are then submitted to the same heckling operation. The tow made in the heckling process is cleared from the heckle teeth, as they revolve, by doffers *l, l*, which in travelling upwards are, by passing over special guide rollers *e, e*, projected out from the line of the heckle teeth. The doffers themselves are cleared by fixed combs *d, d*, and the tow falling down is collected in troughs *k, k* on each side of the machine. Tow, which is a much less valuable substance than dressed line, undergoes a somewhat different preparing process, and is used only for the lower numbers of yarn.

Preparing.—The various operations in this stage have for their object the proper assortment of dressed line into qualities fit for spinning the different counts or sizes of yarn for which it may be suitable, and the drawing out of the fibres to a perfectly level and uniform continuous ribbon or sliver, containing throughout an equal quantity of fibres in any given length. From the heckling the now smooth, glossy, and clean sticks are taken to the sorting room, where they are assorted into different qualities by the "line sorter," who judges by both eye and touch the quality and capabilities of the fibre. So sorted, the material is passed to the spreading and drawing frames, a series or system of machines all similar in construction and effect. The essential features of the spreading frame are—(1) the feeding cloth or creasing sheet, which delivers the flax to (2) a pair of "feed and jockey" rollers, which pass it on (3) to the gill frame or fallers. The gill frame con-

ists of a series of narrow heckle bars, with short closely studded teeth, which travel between the feed rollers and the drawing or "boss and pressing" rollers to be immediately attended to. They are, by an endless screw arrangement, carried forward at the rate at which the flax is delivered to them, and when they reach the end of their course they fall under, and by a similar screw arrangement are brought back to the starting point; and thus they form an endless moving level toothed platform for carrying away the flax from the feed rollers. The drawing rollers grip the fibre as it leaves the gill, and, as they revolve much more rapidly than the feeding rollers, the fibre is drawn out through the gill teeth say to twenty or thirty times the length it had on the feeding board, and is consequently reduced to a silver or louse ribbon of correspondingly greater tenacity. The silver from the drawing frame is delivered into a tin can which holds 1000 yards, and the machine automatically rings a bell when that length is delivered. From the spreading frame the cans of silver pass to the drawing frames, where from four to twelve silvers combined are passed through feed rollers over gills, and drawn out by drawing rollers to the thickness of one. A third and fourth similar doubling and drawing may be embraced in a preparing system, so that the number of doublings the flax undergoes, before it arrives at the roving frame, may amount to from one thousand to one hundred thousand, according to the quality of yarn in progress. Thus, for example, the doublings on one preparing system maybe $6 \times 12 \times 12 \times 12 \times 6 = 82,944$. The silvers delivered by the last drawing frame are taken to the roving frame, where they are singly passed through feed rollers and over gills, and, after drafting to sufficient tenacity, slightly twisted by flyers and wound on bobbins, in which condition the material—termed "rove" or "rovings"—is ready for the spinning frame.

The preparation of tow for spinning differs in essential features from the processes above described. Tow from different sources, such as scutching tow, heckle tow, &c., differs considerably in quality and value, some being very impure, filled with woody shives, &c., while other kinds are comparatively open and clean. A preliminary opening and cleaning is necessary for the dirty machined tow, and in general thereafter they are passed through two carding engines called respectively the breaker and the finisher cards till the shives from their processes are ready for the drawing and roving frames. In the case of fine clean tows on the other hand, passing through a single carding engine may be sufficient. The processes which follow the carding do not differ materially from those followed in the preparation of rove from fine flax.

Spinning.—The spinning operation, which follows the roving, is done in two principal ways, called respectively dry spinning and wet spinning, the first being used for the lower counts or heavier yarns, while the second is exclusively adopted in the preparation of fine yarns up to the highest counts manufactured. The spinning frame does not differ in principle from the throstle spinning machine used in the cotton manufacture (see COTTON, vol. VI. p. 495). The bobbins of flax rove are arranged in rows on each side of the frame (the spinning frames being all double) on pins in an inclined plane A (fig. 2). The rove passes downwards through an eyelet or guide *l* to a pair of nipping rollers *p, p*, between which and the final drawing rollers *c, c*, placed in the case of dry spinning from 18 to 22 inches lower down, the fibre receives its final draft while passing over and under cylinders *d* and guide-plate *g*, and attains that degree of tenacity which the finished yarn must possess. From the last rollers the now attenuated material, in passing to the flyers *f*, receives the degree of twist which compacts the fibres into the round hard cord which constitutes spun yarn; and from the flyers it is wound on the more slowly rotating spool *e* within the flyer arms, centred on the spindle *S*. In wet spinning the general sequence of operations is the

same, but the rove, as unwound from its bobbin, first passes through a trough of water heated to about 120° Fahr; and, moreover, the interval between the two pairs of rollers in which the drawing out of the rove is accomplished is very much shorter.

The influence of the hot water on the flax fibre appears to be that it softens the gummy principle which binds the separate cells together, and thereby allows the elementary cells to be drawn out without breaking the continuity of the fibre, and further it makes a finer, smoother, and more uniform strand than can be obtained by dry spinning. The extent to which the original strick of flax as laid on the feeding roller for (say) the production of a 50 lea yarn is, by doublings and drawings, extended, when it reaches the spinning spindle, may be stated thus—35 times on spreading frame, 15 times on first drawing frame, 15 times on second drawing frame, 14 times on third drawing frame, 15 times on roving frame, and 10 times on spinning frame, in all 16,537,500 times its original length, with $8 \times 12 \times 16 = 1536$ doublings on the three drawing frames. That is to say, 1 yard of heckled line fed into the spreading frame is spread out, mixed with other fibres, to a length of about 9400 miles of yarn. In the case of fine yarns, by the additional drawings given, the doublings and elongations are very much greater.

The next operation is reeling from the bobbins into hanks. By Act of Parliament, throughout the United Kingdom the standard measure of flax yarn is the "lea," called also in Scotland the "cut" of 300 yards. The flax is wound or reeled on a reel having a circumference of 90 inches ($3\frac{1}{2}$ yards) making "a thread," and one hundred and twenty such threads form a lea. The grist or quality of all fine yarns is estimated by the number of leas in a pound, thus "50 lea" indicates that there are 50 leas or cuts of 300 yards each in a pound of the yarn as denominated. With the heavier yarns in Scotland the quality is indicated by their weight per "spindles" of 48 cuts or leas, thus "3 lb tow yarn" is such as weighs 3 lb per spindle, equivalent to "16 lea."

The hanks of yarn from wet spinning are either dried in a loft with artificial heat, or, in rural localities, exposed over ropes in the open air. When dry they are twisted back and forward to take the wiry feeling out of the yarn, and made up in bundles for the market as "grey yarn." English and Irish spinners make up their yarns into "bundles" of 20 hanks, each hank containing 10 leas; Scotch manufacturers, on the other hand, adhere to the spindle containing 4 hanks of 12 cuts or leas.

Commercial quantities of yarn range from about 6 lb tow yarns (8 lea) up to 160 lea line yarn. Very much finer yarn up even to 400 lea may be spun from the system of machines found in many

FIG. 2—Section of Dry Spinning Frame

It is only in Ireland that the linen industries during the above period have exhibited a healthy expansion. To that country alone the following figures apply —

	1828	1861	1870	1880
Number of factories	112	217	312	—
" spindles	268,000 (1828)	670,000	667,000 (1871)	911,000
" power looms	2,631	4,938	14,509	21,153

The number of flax spindles and power-looms in the European factories in 1881 is given in the *Annual Report of the Irish Flax Supply Association* as follows:—

	Spindles	Power- Looms		Spindles	Power- Looms
Ireland	879,916	21,177	Russia	160,000	8,000
Scotland	265,262	16,756	Italy	69,328	722
Denmark	199,596	4,061	Switzerland	9,000	—
France	470,000	22,000	Holland	7,700	1,200
Austria-Hungary	100,440	600	Sweden	9,610	88
Germany	113,467	8,000	Spain	30,235,624	2,713,129
Belgium	223,140	6,755			1,000

In all these returns no account is taken of the hand-loom in use, although in most of the Continental districts hand loom weaving is more common than weaving by power.

The amount and declared value of the exports of linens, linen yarn, &c., from the United Kingdom at intervals extending over fifty years is thus stated from official sources:—

Year	Linen Manufactures	Thread, &c.	Yarns
	Yards	Value in £	Value in £
1831	60,283,909	2,400,613	61,803
1841	95,721,761	3,184,597	111,261
1851	123,108,723	3,822,859	124,491
1861	118,892,469	3,671,131	103,773
1871	226,467,477	5,911,463	202,581
1881	179,884,800	5,185,490	280,350
			16,582,500
			2,087,173

The principal consumers of British linen manufactures are indicated in the following table, showing the exports for the year 1881:—

Country	Yards	Value in £	Yarns
	Yards	Value in £	Value in £
United States	11,090,000	2,544,910	—
Spanish West Indies	10,085,000	447,053	—
Australia	13,326,200	404,017	—
Germany	4,480,000	269,218	2,476,800
British North America	6,381,000	326,287	800,165
France	3,718,000	171,924	1,627,200
Holland	758,300	21,241	2,488,100
Belgium	—	—	1,629,800
Spain and Corsica	—	—	126,619
Other countries	54,720,000	1,689,477	9,651,600
Total	168,845,500	4,868,839	13,285,500
To which add —			
Denmark, checked and printed	4,400,000	161,118	—
France	3,308,000	163,972	—
Sweden and silk	—	—	2,857,100
Thread for sewing	—	—	202,584
Unenumerated	—	—	240,220
Total linen manufactures	179,884,800	5,165,059	—
" yarn, thread, &c.	—	1,737,482	—
" value of exports	—	6,902,541	—

(J. P. A.)

LING (*Molva vulgaris*), a fish of the cod-fish family (*Gadidae*), readily recognized by its long body, two dorsal fins (of which the anterior is much shorter than the posterior), single long anal fin, separate caudal fin, a barbel on the chin, and large teeth in the lower jaw and on the palate. Its usual length is from 3 to 4 feet, but larger individuals of 5 or 6 feet in length, and some seventy pounds in weight, have been taken. The ling is found in the North Atlantic, from Spitzbergen and Iceland southwards to the coast of Portugal. Its proper home is the German Ocean; especially on the coasts of Norway, Denmark, Great Britain, and Ireland it occurs in great abundance, generally at some distance from the land, in depths varying between 50 and 100 fathoms. During the winter months it approaches the shores, when great numbers are caught by means of long lines. On the American side of the ocean it is less common, although generally distributed along the south coast of Greenland, and on the banks of Newfoundland. This fish is one of

the most valuable species of the cod-fish family, a certain number are consumed fresh, but by far the greater portion are prepared for exportation to various countries on the Continent (Germany, Spain, Italy). They are either salted and sold as "salt-fish," or split from head to tail and dried, forming, with similarly prepared cod and cod-fish, the article of which during Lent immense quantities are consumed in Germany and elsewhere under the name of "stock-fish." Also the oil is frequently extracted from the liver and used by the poorer classes of the coast population for the lamp or as medicine.

LING. See HEATH.

LINGARD, JOHN (1771–1851), the Roman Catholic historian of England, was born of humble parentage at Winchester on February 5, 1771. His intellectual abilities began to manifest themselves at a very early age, and in 1783 he was sent to the English college at Douay, where he continued until shortly after the declaration of war by England (1793). For some time after his return to England he lived as tutor in the family of Lord Stourton, but in October 1794 he settled along with seven other former members of the old Douay college at Crook Hall near Durham, where on the completion of his theological course he became vice-president of the reorganized seminary. In 1795 he was ordained priest, and soon afterwards undertook the charge of the chairs of natural and moral philosophy. In 1808 he accompanied the community of Crook Hall to the new and more commodious buildings at Ushaw, Durham, but in 1811, after declining the presidency of the college at Maynooth, he withdrew to the secluded mission at Hornby in Lancashire, where for the rest of his life he found the leisure which his literary pursuits demanded. In 1817 he visited Rome, where he made some researches in the Vatican Library, and also negotiated some business connected with the English college. In 1831 Pope Pius VII. created him doctor of divinity and of canon and civil law, and in 1835 Leo XII. said to have made him cardinal *in petto*. He died at Hornby on July 17, 1851.

Lingard was the author of a considerable number of occasional and ephemeral writings of an unwelcome controversial character. He also wrote *The Antiquities of the Anglo-Saxon Church* (1806), of which a third and greatly enlarged edition appeared in 1845 under the title *The History and Antiquities of the Anglo-Saxon Church, containing an account of its origin, government, doctrines, worship, revenues, and clerical and monastic institutions*, but the work with which his name is chiefly associated is *A History of England, from the first invasion by the Romans to the commencement of the reign of William III.*, which appeared originally in 8 vols. at intervals between 1819 and 1830. Three successive subsequent editions had the benefit of extensive revision by the author, a fifth edition in 10 vols. 8vo appeared in 1849, and a sixth, with life of the author by Tierney prefixed to vol. i, in 1854–56. Soon after its appearance it was translated into French, German, and Italian. It is a work of ability and research, and, though Cardinal Wiseman certainly claimed too much for its author when he called him "the only impartial historian of our country," yet the candid and dispassionate student will always find it profitable to learn from the pages of Lingard the aspects which the events of English history presented to the mind of an able and intense Roman Catholic in the earlier decades of the 19th century.

LINKÖPING, a city of Sweden, the see of a bishop, and the chief town of the province of East Gothland, is situated in a fertile plain 21 miles by rail south-west of Stockholm, and communicates with Lake Roxen (3 mile to the north) and the Gata and Kinda canals by means of the now navigable Sångån. Most of the houses are of wood. The cathedral (1160–1499), a Romanesque building with a Gothic choir, is, next to the cathedral of Upsala, the largest church in Sweden, and, since the cathedral of Trondheim has lost so many of its treasures, presents the richest variety of objects of interest to the student of medieval art in the country. In the church of St. Lawrence, also called the Church of the Estates, are some paintings

fishments, apart from those mentioned in connexion with the town, being grist-mills, distilleries, chemical works, glass works, spade and shovel works, and a pottery.

The climate of the county hardly differs from that of the western portion of Midlothian. The annual rainfall, however, is somewhat greater, and is a fifth more than that of East Lothian: for the twenty-one years ending 1880 the mean at Linlithgow was 31·76 inches, while at East Linton (east of Haddington) it was 26·52.¹

Linlithgow is classed as a mixed agricultural and pastoral county, the agricultural element, however, preponderates largely, though the area of permanent pasture has been increasing. It is calculated that of the total area of 81,114 acres about 20,000 acres consist of the best sorts of clay (carae, &c.), 22,700 of clay on a cold bottom, 9600 of loam, as much of light gravel and sand, 14,000 of moorland and high rocky ground, and 1500 of peat. Only a very small part of the arable land remains unenclosed; the parish of Livingston, which in the beginning of last century was nearly covered with heath and juniper, is now all under rotation. Bathgate and Torphichen contain patches of peat moss and swamp. In Carnden and Dalmealy, and generally along the coast, the soil is light and early, though in some parts it varies so much that no single term is applicable to any considerable area. According to the agricultural returns for 1881, the corn crops occupied 17,847 acres, green crops 7261, clover and grass under rotation 12,980, permanent pasture (exclusive of heath or mountain land) 21,330. Oats are the most important of the cereals, 10,318 acres, and barley comes next with 4574 acres; increase on the 8757 acres of 1856. Wheat has been steadily losing ground, while 1856 showed 4643 acres, 1881 gives only 1450. Means, which used to occupy about 1000 acres, are now reduced to 655. An increasing area is devoted to clover and grasses for hay; but on the other hand the turnip area has been considerably reduced—5143 acres in 1856, 3801 in 1881. The extent of land under potatoes has slightly increased,—3023 acres for 1881, 2355 being the average for 1856–75. Cattle breeding is not much attended to, but a considerable number of animals are bought and fattened, and dairy farming is largely prosecuted, the fresh butter and cream being sent mainly to Edinburgh, but also to Newcastle, &c. Very little cheese is made. As a sheep-farming county Linlithgow stands very low—the returns giving 17,605 head in 1881, 28,070 in 1856. But few horses are bred, and the number of those in the county has remained wonderfully steady for the last fifty years. Hags have grown greatly fewer—2166 in 1866, and only 1442 in 1881.

The average extent of the farms is 108 acres, rather less than in Midlothian, of the total 542 more than 200 do not exceed 50 acres, and only 85 rise above 600. Very little of the land is rented at more than 28 per acre, an average of 25 to 28, 10s. for the best districts, of 80s. to 85s. for medium soils, and 15s. to 25s. for the worst land, will not be wide of the mark. "The leases of the arable lands are almost invariably for nineteen years, and grass lands are usually let annually by public auction, though in some instances they are taken for a period of three or five years."²

Though it is only in the neighbourhood of the principal manor-houses that large stretches of wood exist, the county as a tree-growing district rises considerably above the average for Scotland,—the woodland area being returned as 4899 acres in 1881, or one-sixteenth of the whole (Edinburgh shows one-twentieth). The finest woods are those of Hopetoun (where the beech avenues are especially noted), Newliston, Kinnell, and Dalmealy. Much of the old timber has been recently cut down, but replanting has been vigorously prosecuted.

The valued rent of the county in 1649 was £78,027 Scots, or about £2652 sterling. In 1806 the real rent was £51,018 sterling, and in 1811, £48,745. The value of railways, the valuation was £180,198 in 1876–77, and £216,011 in 1881–82. In the beginning of the century the county was practically in the hands of between thirty and forty landowners (Trotter). According to the Government returns for 1872–73, the total number of owners was 1555, of which 287 possessed upwards of 1 acre. The proprietors holding estates above 2000 acres were as follows:—Earl of Hopetoun, 11,870 acres; Earl of Rosebery, 5680; Sir William Ballie of Polkennet, 4320; Duke of Hamilton's Trustees, 3604; Lord Carlisle, 2295; William Cowan of Lumbry, 2281; Robert H. J. Stewart of Chanayfield, 2028; Dundas's Trustees, 2052.

Hopetoun House, the seat of the earl of Hopetoun, and the grandest mansion in the county, occupies a fine position between Queensferry and Blackness. Begun about 1696 by Sir William Bruce of Kinross, and completed long afterwards by Mr Adam, it practically occupies the site of the old castle of Abercorn, which

was taken from the Douglas family by James II. in 1455. Dalmealy Park (east of Rosebery) lies about 1½ mile west of Armond, the neighbouring ruins of Barnbougle Castle, an ancient seat of the Mowbrays, have been incorporated with a modern building. Almondell House (earl of Buchan) is situated on the Almond, not far from Mid Calder. Kinnell, a now deserted residence of the dukes of Hamilton, associated with memories of Colonel Latham and Dugald Stewart, is a short distance to the south-west of Bo'ness. On a trap rock jutting out into the fish strands Blackness Castle, now used as a powder magazine, but once one of the "keys of the kingdom, with a busy little port under its protection. Naby Castle (often called West or Seaton Naby), one of the resting places of Queen Mary, is now a mere ruin. Newliston (now owned by T. A. Hog) was for many years the residence of Lord Stair, who first introduced the field cultivation of cabbage, and is said to have laid out the woods according to the plan of the battle of Dettingen. Dundas Castle was the original seat of the Dundas family. Paterson recalls the memory of Walter Smeaton, author of the *Collections concerning the Works, &c. of the Church of Scotland*, and Philipstoun that of John Dunbar, another Scottish ecclesiastical lawyer. Kinnevel was the birthplace and family mansion of Patrick Hamilton.

There are two royal burghs in the county—Linlithgow and Queensferry, and, besides the towns Bathgate, Borrowstonness or Bo'ness, Arnamdale, a number of thriving villages.

The Union Canal connecting the Forth and Clyde Canal with Edinburgh passes along the central valley, and crosses the Almond and Avon by bridges designed by Thomas Telford. The North British Railway has two lines between Edinburgh and Glasgow, which pass through the county as Linlithgow and Bathgate respectively. Queensferry and Bo'ness are both connected with the system by branch-lines, and Bathgate is a junction of some importance.

The population of West Lothian has increased from 17,844 in 1801 to 48,196 (22,482 males and 25,714 females) in 1881. The greatest increase (3801) took place in the decennial period 1851–1861, the least (606) in 1811–21. The females were in excess of the males in every census down to 1841; since then the preponderance has been on the other side. The total population was 23,291 in 1801, 26,879 in 1811, 30,044 in 1821, 33,945 in 1831, and 40,965 in 1871.

Traces of the prehistoric occupation of the county are fairly numerous. On Bowden Hill is an earthenware connected by Mr Glaister and others with the Arturian contest. On Carraprie may be seen the remains of a circular building of unknown but early origin, and at Kippis is a cromlech now surrounded by circles of stones. Stone cists have been discovered at Carlewa, Dalmealy, Newliston, &c. Near Invernoon is a vast accumulation of shells considered by several geologists to be a natural bed, but claimed by antiquaries as an artificial mound, either a kitchen midden or a heap for the manufacture of lime (see David Grove, *Proc. St. Soc. of Ant.*, 1870–71). The Wall of Antoninus lies for a considerable distance within the county, and is believed to give origin to the names Carnden and Walton (see an account of a detailed exploration of the wall in *Fieldian*, 1877, pp. 1023–25). A fine legionary tablet was discovered at Brighams in 1869 (*Proc. St. Soc. of Ant.*, vol. viii.). Roman camps can be distinguished in several places.

At Torphichen* are the remains of a preceptory of the Knights of St John of Jerusalem, partly used as a parish church. The churches of Torphichen, Torcross, Kirkstoun, Uphall, and South Queensferry are of early origin,—Romanesque and Norman Gothic.

LINLITHGOW, the county town of the above county, and a royal and parliamentary burgh, situated in the central valley, 18 miles by rail from Edinburgh, consists almost exclusively of a single street running east and west along both sides of the highway; gardens behind the houses stretch down to the lake or climb the lower slopes of the rising grounds, on which a considerable number of suburban residences have been erected. In the early part of the century the general aspect of the street was antique and picturesque, but the greater proportion of the frontage has been rebuilt or modernized. Apart from the palace and the contiguous church of St Michael, the only edifices of any note are an ancient towerlike building near the railway station, which tradition regards as a mansion of the Knights Templars, the town-house (1688), and the county courts (1865). "Linlithgow for wells" is a proverbial expression; and the cross well in the public

¹ For earlier notices of rainfall, &c., see Trotter's *Agriculture of West Lothian*.

* See Abstract of the Charters . . . in the *Charterology of Torphichen* (ed. 1890).

square in front of the town-house is a striking piece of grotesque carved work in stone, originally erected, it is believed, in the reign of James V, but rebuilt in 1807. The burgh school goes back to the pre-Reformation times. Shoemaking and tanning are the leading industries; but a large distillery and (in the neighbourhood) two paper mills, glue works, and a soap factory add considerably to the business of the place. Linen bleaching is altogether a thing of the past. A grain market is held every Friday. The riding of the marches of the burgh is still performed annually by the magistrates and trades. The population of the burgh was 2282 in 1792-93, 3843 in 1861, 3690 in 1871, and 3913 in 1881.

Linthgow Palace is by general consent the finest ruin of its kind in Scotland. Heavy but effective, the somber walls rise above the green knolls of the promontory which divides the lake into two nearly equal portions. In plan it is almost square (168 by 174 feet), enclosing a court (91 by 88 feet), in the centre of which stands the ruined fountain used as a model for that erected in front of Holyrood Palace. At each corner there is a tower with an unusual spiral staircase,—that on the north-west angle being crowned by a little octagonal turret known as "Queen Margaret's Bower," from the tradition that it was there that the consort of James IV. sat and watched for his return from Flodden. The oldest portion of the building is probably the west side, whose massive masonry, hardly broken by a single window, is supposed to date in part from the time of James III., but the larger part of the south and east sides belong to James V., about 1535, and the north side was rebuilt in 1610-20. Of James V.'s portion, which is architecturally the richest, the main apartments are the Lyon chamber or parliament hall, and the chapel royal. The grand entrance approached by a drawbridge, was on the east side, above the gate way are still some weather-worn remains of rich allegorical designs, once resplendent with colour. A few yards to the south of the palace is the church of St. Michael, a Gothic (Scottish Decorated) building (180 feet long including the tower) probably founded in the 12th century, but mainly built in the 15th century. The central west front steeple was till 1821 topped by a crown like that of St. Giles, Edinburgh.

Linthgow (wrongly identified with a Roman Lindum) was a royal burgh with a castle and an endowed church as far back as the reign of David I. Edward I., who had encamped there the night before the battle of Falkirk (1295), wintered at Linthgow in 1301, and next year built "a pale (castle) well and strong," which in 1318 was captured by the Scots through the assistance of William Bannock or Bannock and his famous bay-cart. Later in the century (1369) the customs of Linthgow yielded more than those of any other chief town except Edinburgh; and the burgh was taken along with Lanark to supply the place of Berwick and Roxburgh in the court of the Four Burghs (1368). Robert II. granted it a charter of immunities, the oldest still preserved, in 1384. The palace becoming a favourite residence of the kings of Scotland, and often forming part of his marriage settlement of their consorts (Mary of Guelders, 1449; Margaret of Denmark, 1468; Margaret of England, 1608), as frequently mentioned in Scottish history, James V. was born within its walls in 1512, and his daughter Mary, December 7, 1542. In 1570 the Regent Murray was assassinated in the High Street by Hamilton of Bothwellhaugh. In 1600 the title earl of Linthgow was bestowed on Alexander, Lord Livingston, by James VI., who after his accession to the English throne retained an affection for the palace, and visited it again in 1617. The university of Edinburgh took refuge at Linthgow from the plague in 1645-46; and in the same year the national parliament, which had often sat in the palace, was held there for the last time. The public burning of the Covenant (1661), the passing of Prince Charles through the town in 1746, and the burning of the palace by Hawley's dragoons in 1746 are the chief remaining facts in the local annals. Most of the privileges which Linthgow enjoyed have dropped away. The rise of Bonness gave the last blow to the prosperity of its port at Blackness; its burgh lands have all been sold; and, after gaining its case three times in the Court of Session, it was deprived (1859) by the House of Lords of any claim to levy bridge toll and custom from the Edinburgh and Glasgow Railway.

LINNÆUS (1707-1778). Carl von Linné, better known under his earlier name of Carolus Linnaeus, was born 13th May 1707, o.s., at Råshult, in the parish of Stenbrohult, in the province of Småland, Sweden.² His parents were Nils Linnaeus, the minister, afterwards pastor, of the parish, and Christina, the daughter of Broderusius, the previous incumbent; Carl, the subject of our notice, being their eldest child. When only four years old he was much impressed with his father's conversation with some of his people concerning the properties and names of certain of the local plants of economic value; from that time he constantly asked his father about the quality and nature of every plant he met with, often asking more than his father could answer, at other times, having forgotten the information previously given him, he was threatened with a refusal to answer his queries unless he promised to remember what he was told. To this early discipline Linnaeus afterwards ascribed his tenacious memory, which, added to his extreme sharpness of sight, laid the foundations of his eminence as a reforming naturalist.

His formal education began in 1714, when he was put under the private tuition of Telandier, and three years later he entered the primary school at Wexiö. In 1719 he was committed to the care of Gabriel Hok, who afterwards married his pupil's sister Anna Maria, this preceptor had greater skill as a teacher than his predecessors, and was less severe; still he was unable to overcome the distaste the youth had acquired for ordinary scholastic studies. During his last years at school Linnaeus took advantage of the greater liberty then allowed him to ramble in search of plants.

In 1724 he passed from the school to the gymnasium, carrying with him the same dislike for all those studies which his father considered necessary for admission to holy orders, his father's intention being to bring up his son in his own profession. Botany, a science at that time entirely neglected, almost wholly engrossed his attention; he formed a small library of the few Swedish writers who had treated of plants, which he was constantly poring over, although unable to comprehend all he found in their volumes.

In 1726 his father came to Wexiö, hoping to hear a good report of the two years' study of his son, but, whilst there was no complaint as regards his moral deportment, his progress in the prescribed studies had been so unsatisfactory that his father was recommended to apprentice him to a tailor or shoemaker, in preference to giving him a learned education, for which he was evidently unfitted. The old clergyman, deeply grieved at this poor return for his struggles to keep his son at school during the previous twelve years, went to visit Dr Rothman, a medical practitioner and lecturer on physics in the town, to consult him regarding a bodily ailment from which he was suffering. In the course of conversation he mentioned his mortification at his son's dullness, when Rothman expressed his confident belief that he could end the troubles of both father and son, and that Carl, though extremely backward in theological studies, would yet distinguish himself in medicine and natural history. Rothman further offered to board and lodge Carl during the twelvemonth more which must be passed in the gymnasium. A short time after this, Rothman gave his pupil a course of private instruction in physiology with great success, the young man acquiring himself excellently on examination. His tutor also gave

² The new style being then in process of gradual adoption in Sweden, the year 1704 was regarded as a common year in that country, consequently the true date of Linnaeus's birth, according to our present reckoning, was 23d May 1707, the commonly received date, 24th May, being an error due to supplanting the calendar in Sweden and Russia at that time to be identical.

him hints as to the proper manner of studying plants, and directed his attention to Tournefort's system of arrangement, which was founded on the differences in the flowers.

He proceeded to the university of Lund in 1737, bearing a deviously worded testimonium from Nils Krok, the rector of the gymnasium, to the effect that shrubs in a garden may disappoint the cares of the gardener, but if transplanted into different soil may prosper, therefore the bearer was sent to the university, where, perchance, he might find a more propitious climate. His former preceptor Hok kept back this doubtful recommendation, and presented Linnæus to the rector and dean as his own private pupil, thus procuring his matriculation.

Whilst studying here, Linnæus lodged at the house of Dr. Kilian Stobæus, afterwards professor of medicine, and physician to the king, who possessed an excellent museum of minerals, shells, birds, and dried plants, the methods of preservation here adopted were as a revelation to the young student, and taught him how to prepare his own acquisitions. Stobæus suffered greatly from ill-health, he was also lame, and one-eyed, but he was an amiable and extremely able man, having a large practice among the wealthier classes in the province of Skåne. Linnæus was sometimes called upon to assist the physician by writing the prescriptions, but as he wrote a bad hand, he was frequently sent away again. In those days physicians wrote legibly.

A German student named Koulas also lodged with Stobæus, and amongst the indulgences he enjoyed was that of access to the library of his landlord; with his fellow-student Linnæus formed a close friendship, and in return for instruction in the physiology which Linnæus had learned of Dr. Rothman, Koulas supplied him with volumes from the book-shelves of Stobæus, which were read by him stealthily at night. The mother of Stobæus, who was old and wakeful, noticed that there was constantly a light in Linnæus's room, and, being afraid of fire, decried her son to repenting the young man for his carelessness. Two nights afterwards, Stobæus went into Linnæus's chamber at eleven o'clock, expecting to find him asleep, but was astonished to find him poring over books. He was forced to confess whence these were obtained, and was at once ordered to bed; but the next morning, being further questioned, he was granted full liberty to use the library, and perfect familiarity was accorded by the doctor, who, having no children, held out hopes of making the young student his heir.

Whilst botanizing in the spring of 1738, Linnæus was attacked by what he considered to be a venomous animal, afterwards named by him *Furva infernalis*, in allusion to the torment and danger he suffered from it; after his recovery, he passed the summer at his father's house in Småland. Here he again met Rothman, who strongly advised him to quit Lund and to go to Upsala, where he would find greater facilities for the prosecution of his medical studies, and possibly obtain some scholarship to eke out his scanty means. Linnæus adopted his patron's advice, and started for Upsala with a sum of £8 sterling, that being all he was to expect from his parents. At this sort of learning his slender funds were soon exhausted, being young and unknown, he found no means of earning money by lecturing or teaching; he became dependent on chance generosity for a meal, and had to repair his shoes with folded paper. He could not well return to Lund, for Stobæus had taken offence at his departing without consulting him, and, besides, the journey required money which he did not possess.

In the autumn of this year, 1739, Linnæus was engaged intently examining some plants growing in the academical garden, when a venerable clergyman asked him what he

was studying, whether he understood botany, whence he came, and how long he had been busied in the study. After being questioned at length, he was requested to follow his companion home; there he discovered him to be Dr. Olaf Celsius, professor of theology, at that time working at his *Herobotanicon*, which saw the light nearly twenty years later. When the professor saw Linnæus's collections he was still more impressed, and, finding him necessitous, he offered him board and lodging, he afterwards admitted him to close intimacy, and allowed him the free use of his rich library. The temporary adjuncts of the faculty of medicine being incompetent, Linnæus, by the recommendation of Celsius, was able to get some private pupils, and thereby to assume a more creditable appearance.

At this time there was only one medical student who distinguished himself by diligence in study, and that was Peter Artedius, who afterwards styled himself Artedi. A close friendship sprang up between the two young men, they studied in concert, and vied with each other in their attainments, with perfect good temper, though of very diverse dispositions. Linnæus was sovereign in ornithology, entomology, and botany, Artedi reserving to himself the umbelliferous plants, fishes, and amphibia. A silence, almost total, prevailed in the university at this time on topics of natural history; during his whole curriculum Linnæus did not hear a single public lecture delivered on anatomy, botany, or chemistry.

During this period of intense receptivity, he came upon a critique which ultimately led to the establishment of his artificial system of plant classification. This was a review of Vaillant's *Sermo de Structura Florum*, Leyden, 1718,¹ a thin quarto in French and Latin, it set him upon examining the stamens and pistils of flowers, and becoming convinced of the paramount importance of these organs, he formed the idea of basing a system of arrangement upon them. Another work by Wallin, *Päqors förvar, sive Nuptia Alborum Diseratatio*, Upsala, 1729, having fallen into his hands, he drew up a short treatise on the sexes of plants, and showed it to Dr. Celsius, who put it into the hands of the younger Olaf Rudbeck, at that time professor of botany in the university. In the following year Rudbeck, whose advanced age compelled him to lecture by deputy, appointed Linnæus his adjunct; in the spring of 1730, therefore, the latter began his lectures, and was accompanied by many pupils on his botanical excursions. The academic garden was entirely remodelled under his auspices, and furnished with many rare species, he being now in a position to direct the gardener, whereas in the year before he had actually solicited appointment to the vacant post of gardener, which was refused him on the ground of his capacity for better things.

His evenings were now devoted to the preparation of his epoch-making books, which were issued several years afterwards in the Netherlands. His position at the university having become unpleasant, he readily undertook to explore the little known country of Lapland, at the cost of the Academy of Sciences of Upsala. He started thence on May 12, 1732 o.s., carrying all his luggage on his back, journeying at first on horseback along the road skirting the coast to Umeå, thence by boat up the river to Lyckeel within the Arctic Circle, penetrating to what he terms Olycksmyran (i.e., the unlucky marsh) in spite of the melting of the ice, which made travelling in that part almost impossible. Unable to penetrate farther into the interior, he returned to Umeå, still skirting the sea-shore by Fittå to Luleå. From this latter place he made a lone excursion to the north-west by Jockmoock and Qvickjock;

¹ This work has a serious mistake on both title pages; it is corrected in the errata, but the correction seems to have escaped the notice of every bibliographer.

then, crossing the mountain range, he came out upon the coast of Finmark. He retraced his steps to Luleå, and at Celix he learned the art of assaying "in two days and a night," continuing his journey through Torné, and the eastern coast of the gulf of Bothnia to Åbo, where he rested eight days, and finally reached Upsala by sea. The distance traversed in this tour was upwards of 4600 English statute miles, the cost of his journey is given at 112 silver dollars, or less than £25 sterling. His own account of the journey was published in English by Sir J. E. Smith, under the title *Lachenis Lapponica*, in 1811, the scientific results were published in his *Flora Lapponica*, Amsterdam, 1737. In 1733 Linnæus was engaged in teaching the method of assaying ores, and hoped to be allowed to lecture on botany; but a quarrel broke out between a rival, Rosen, and himself, the former having, by private influence, contrived to get a prohibition put on all private lectures on medicine in the university. Linnæus, enraged at finding his livelihood thus cut off, went so far as to draw his sword upon Rosen, but was prevented from harming his antagonist. At this juncture the governor of Dalecarlia invited Linnæus to travel through his province, as he had done through Lapland. Whilst on this journey he lectured at Fahlun to large audiences; Brouallus, the chaplain there, afterwards bishop of Åbo, now strongly urged Linnæus to go abroad and take his degree of M.D. at a foreign university, by which means he could afterwards settle where he pleased. Linnæus, having become attached to the eldest daughter of Dr Moré or Moræus, left Sweden in 1735 to seek his fortune in the manner stated, and to return to claim her hand.

He travelled by Lübeck and Hamburg; detecting a seven-headed hydra to be a fabrication at the latter, he was obliged to quit the town in haste to avoid the wrath of its possessor. From Altona he went by sea to Amsterdam, staying there a week; he then proceeded to Harderwyk, where he went through the requisite examination, and defended his thesis on the cause of intermittent fever. His scanty funds were now nearly spent, but he passed on through Haarlem to Leyden; there he called on Gronovius, who, returning the visit, was shown the *Systema Naturæ* in MS., and was so greatly astonished at it that he sent it to press at his own expense. The first edition was in eight folio sheets; the subsequent editions were in 8vo; and the twelfth immensely enlarged edition appeared during the author's lifetime. This famous system, which, artificial as it was, substituted order for confusion, largely made its way on account of the lucid and admirable laws, and comments on them, which were issued almost at the same time. See BOTANY, vol. iv. p. 80. Boerhaave, whom Linnæus saw after waiting eight days for admission, recommended him to Burman at Amsterdam, where he stayed a twelvemonth, living at the house of the professor. While there he issued his *Fundamenta Botanica*, an unassuming small octavo, which has exercised immense influence. The wealthy banker Clifford having invited Linnæus to visit his magnificent garden at Hartecamp, he remained there, living like a prince, but working most assiduously in the garden and library, both of which were kept up without regard to cost. His *Flora Lapponica* was now printed, containing a description of the genus *Linnaea*, by his friend Gronovius; he selected this plant to bear his name, from a similarity, as he thought, between it and himself. Whilst living with Clifford, Linnæus met with his old fellow-student Artedi, who was quite destitute, having spent all his money in London; Linnæus introduced him to Seba, then working at fishes, Artedi's chief object of study; he worked hard at describing them, until only six remained undescribed, when he unfortunately fell into a canal at night, and was drowned.

Linnæus persuaded Clifford to redeem the manuscript, and he published it as a memorial of his deceased friend.

In 1736 Linnæus visited England. He was warmly recommended by Boerhaave to Sir Hans Sloane, but the old collector seems to have received him coldly. A better reception awaited him at Oxford, where Dr Shaw welcomed him cordially, Dillenius, the professor of botany there, was icy at first, but afterwards thawed completely, kept him a month, and even offered to share the emoluments of the chair with him. At Chelsea he saw Philip Miller, and took some plants thence to Clifford; but certain other stories which are current about Linnæus's visit to England are of very doubtful authenticity.

On his return to the Netherlands he completed the printing of his *Genæa Plantarum*, a volume which must be considered the starting point of modern systematic botany, Tournefort formed many genera, but Linnæus was the first to circumscribe them. During the same year, 1737, Linnæus finished arranging Clifford's collection of plants, living and dried; these were described in the *Hortus Cliffortianus*, a folio illustrated with engravings by Ehret; this book was entirely written in nine months. During the compilation he used to "amuse" himself with drawing up the *Critica Botanica*, also printed in the Netherlands. But this strenuous and unremitting labour told upon him, the atmosphere of the Low Countries seemed to oppress him beyond endurance, he resented all Clifford's entreaties to remain with him, and started homewards.

Van Royen managed to detain him a year at Leyden, to help in rearranging the garden, thereby offending Clifford, whom he had quitted on the plea of hastening back to Sweden. Linnæus now published his *Classis Plantarum*, and almost at the same time appeared Van Royen's *Hortus Leydenæ* and Gronovius's *Flora Fervicina*, both of these being drawn up on the Linnæan system. In 1738 Boerhaave pressed Linnæus to accept a post at Surinam; he declined this for himself, but passed it on to Johan Bartsch of Königsberg, a member with himself of a select club of naturalists at Leyden. Bartsch ultimately fell a victim to the climate of that colony.

While residing at Leyden Linnæus was warned that one of his acquaintances was endeavouring to supplant him in the affections of Sara Moré; he intended to set out at once, but was attacked by ague before he could start. Clifford, hearing of this, took Linnæus to his own house again, and would not suffer him to depart until he was sufficiently well. His complete recovery, however, did not take place until he had gained the higher country of Brabant, where in one day he felt himself entirely renovated. He continued his journey to Paris, where he visited Antoine and Bernard de Jussieu, botanizing with the latter. Abandoning all notion of returning through Germany, he went to Rouen, sailed for Sweden, and landed at Helsingborg.

Linnæus established himself in September, 1738, as physician in Stockholm, but, being unknown as a medical man, no one at first cared to consult him, a great change from the attention paid to him abroad; he himself declared "that, had he not been in love, he would certainly have left his native country." By degrees he found patients, was then appointed naval physician at Stockholm, with minor appointments, and was married on the 26th June 1739.

Early in 1740 Hædbeck died, and Roberg resigned; the chairs of botany and medicine at Upsala being thus vacant, Rosen and Linnæus were chosen respectively to fill them. The former rivals afterwards agreed to exchange professorships to their mutual benefit; in 1741, previous to this exchange, Linnæus travelled through Olund and Gothland, by command of the state, publishing his results in *Öländska och Gothländska Resa*, 1745. The index to this volume shows the first employment of trivial names in nomenclature.

Henceforward his life was a continuous course of prosperity, his time being taken up by teaching and the preparation of other works. In the year 1745 he issued his *Flora Suecica* and *Flora Suecica*, the latter having occupied his attention during fifteen years; afterwards, two volumes of observations made during journeys in Sweden, *Waldgäta Resa*, Stockholm, 1747, and *Skånska Resa*, Stockholm, 1751. He examined the collections made many years before in Ceylon by Harmsen, the full publication taking place in his *Flora Zeylanica*, Stockholm, 1747. In 1748 he brought out his *Hortus Upsalensis*, showing that he had added eleven hundred species to those formerly in cultivation in that garden. In 1750 his *Philosophia Botanica* was given to the world; it consists of a commentary on the various axioms he had published in 1735 in his *Fundamenta Botanica*, and was dictated to his pupil Löffling, while the professor was confined to his bed by an attack of gout so violent as to threaten his life; he attributed his recovery to eating plentifully of wood-strawberries, a regimen he afterwards carefully observed. A much slighter attack in the following year was mainly cured by the pleasure caused by Kalm bringing home many new plants from Canada.

He catalogued the Queen's Museum at Drottningholm, and the King's at Ulriksdal, but the most important work of this period of his life is unquestionably his *Species Plantarum*, Stockholm, 1753,—a second edition being issued in 1762. In this volume the trivial names are fully set forth; although they had been previously shadowed forth by Linnæus and others, yet to him belongs the merit of establishing the use of a single epithet in addition to the generic name. In the same year Linnæus was created knight of the Polar Star, the first time a scientific man had been raised to that honour in Sweden.

In 1755 he was invited by the king of Spain to settle in that country, with a liberal salary, and full liberty of conscience, but he declined on the ground that whatever merits he possessed should be devoted to his country's service; Löffling was sent instead, but died within two years. He was enabled now to purchase the estate of Söfs and Hammarby; at the latter he built his museum of stone, to guard against loss by fire. His lectures at the university drew men from all parts of the world; the normal number of students at Upsala was five hundred, whilst he occupied the chair of botany there it rose to fifteen hundred. In 1761 a patent of nobility was granted, antedated to 1757, from which time Linnæus was styled Carl von Linné; his arms were those now borne by the Linnæan Society of London. To his great delight the tea plant was introduced alive into Europe in 1763; this year also his son Carl was allowed to assist his father in his professional duties, and to be trained as his successor.¹ At the age of sixty Linné's memory began to fail; an apoplectic attack in 1774 greatly weakened him; two years after he lost the use of his right side; and he died

10th January 1778, of an ulceration of the bladder. He was buried in the cathedral of Upsala, with every token of universal regret.

In person Linnæus was described as of medium height, with large limbs, brown piercing eyes, and acute vision, and quick-tempered. He was accustomed to sleep five hours in summer and ten in winter. He lived simply, acted promptly, and noted down his observations at the moment. His handwriting was peculiar, and not very easy to read, copies of his own books were interleaved and copiously annotated, every new discovery being posted into its proper place at once, so that new editions were readily prepared when wanted.

With his arrangement seems to have been a passion, he delighted in devising classifications, not only did he systematise the three kingdoms of nature, but even drew up a treatise on the *Genera Morborum*. He found biology a chaos; he left it a cosmos. When he appeared upon the scene, new plants and animals were the source of daily discovery in increasing numbers, due to the increase of trading facilities, he devised schemes of arrangement by which these acquisitions might be sorted provisionally, until their natural affinities should have become clear. He made many mistakes, but the honour due to him for having first enunciated the true principles for defining genera and species, and his uniform use of trivial names, will last so long as biology itself endures. His style is terse and laconic; he methodically treated of each organ in its proper turn, he had a special term for each, the meaning of which did not vary, so that the term did not suggest two ideas at once. The reader cannot doubt the author's intention; his sentences are business-like, and to the point. The omission of the verb in his descriptions was an innovation, and gave an abruptness to his language which was foreign to the writing of his time, but it probably by its succinctness added to the popularity of his works.

By his force of character he shifted the scientific centre of gravity during his life to a small town in Sweden, he was constantly receiving presents and praise from crowds of correspondents in every civilized country and in every station of life, hence it is not surprising that this universal homage should have bred the vanity which disfigures the latter part of his life.

No modern naturalist has impressed so strong an own character with greater force upon his pupils than did Linnæus. He imbued them with his own intense acquisitiveness, reared them in an atmosphere of enthusiasm, trained them to close and accurate observation, and then dispatched them to various parts of the globe. His students being drawn from many quarters, he had an extensive acquaintance, and fell victims to fatigue and unkindly climates, but there was no lack of successors. With these young enthusiasts their master's love was like a gospel; they were eager to extend the knowledge of it, and to contribute to its melioration.

The published works of Linnæus amount to more than one hundred and eighty, including the *Amoenitas Academica*, for which he provided the material, revising them also for press; corrections in his handwriting may be seen in the Banksian and Linnæan Society's libraries. His correspondence was wide and copious. Some of his letters have been published, but the bulk of them remains inédit. Many works remain in MS.; some have lately been published, such as the *Flora Dalecarlica*, and the *Svenska Arbeten*, both edited by Dr Ewald Ahring; those which were issued during the author's life are enumerated by Dr Pulteney in his *General View of the Writings of Linnæus*. (B. D. J.)

LINNELL, JOHN (1792-1882), a richly gifted English painter, was born in London on the 16th of June 1792. His father being a carver and gilder, Linnell was early brought into contact with artists, and when he was ten years old he was already drawing and selling his portraits in chalk and pencil. His first artistic instruction was received from Benjamin West, and he spent a year in the house of John Varley the water-colour painter, where he had William Hunt and Mulready as fellow pupils, and made the acquaintance of Shelley, Godwin, and other men of mark and individuality. In 1808 he was admitted a student of the Royal Academy, where he obtained medals for drawing, modelling, and sculpture. He was also trained as an engraver, and executed a transcript of the Burial of Saul, one of Varley's most impressive pictures. In after life he frequently occupied himself with the burin, publishing, in 1834, a series of outlines from Michelangelo's frescos in the Sistine chapel, and, in 1840, superintending the issue of a selection of places from the pictures in Buckingham Palace, one of them, a Titian landscape, being mezzotinted by himself. At first he supported himself mainly by miniature painting, and by the execution of

¹ Carl von Linné the younger, the elder son of the distinguished naturalist, was born at Fahlun, 20th January 1741. Delicate in constitution, he seemed to be oppressed with his father's reputation and his having to support it. He published two decades of new plants, and three dissertations, contributing also some descriptions to the first edition of *Aiton's Hortus Kewensis*, at the time of his visit to England. He died unmarried at Upsala, 1st November 1788, and his only brother Johan having died in infancy, the succession became extinct in the male line. His mother sold the collections and books of father and son to Dr J. E. Smith, the first president of the Linnæan Society of London. When Smith died in 1828, a subscription was raised to purchase the herbarium and library for the Society, whose property they now remain. Smith sold the collection of minerals in 1796, and added many insects to the Linnæan types, but the herbarium is practically in the same state as when the elder Linné himself last used it. The manuscripts of most of his publications, and the letters he received from his contemporaries, are likewise in the possession of the Society.

larger portraits, such as the likenesses of Mulready, Whately, Peel, and Carlyle. Several of his portraits he engraved with his own hand in line and mezzotint. He also painted many subjects like the St John Preaching, the Covenant of Abraham, and the Journey to Emmaus, in which, while the landscape background is usually prominently insisted upon, the figures are yet of sufficient size and importance to supply the title of the work. But it is mainly in connexion with his long series of paintings of pure landscape that his name is known to the public. When he was only seventeen, his *Removing Timber* carried off the fifty-guinea prize offered by the British Institution for the best landscape, and for many years Linnell was a regular contributor to the exhibitions of that body, and to those of the Royal Academy and the Society of Painters in Oil and Water Colours. His works commonly deal with some scene of typical uneventful English landscape, which is made impressive by a gorgeous effect of sunrise or sunset. They are full of true poetic feeling, and are rich and glowing in colour. His art proved exceptionally remunerative; he was able to command very large prices for his pictures, and about 1850 he purchased a property at Redhill, Surrey, where he resided till his death, on the 20th of January 1882, surrounded by his children—two of them artists like himself—and his children's children, and painting with unabated power till within the last few years of his life. His leisure was greatly occupied with a study of the Scriptures in the original, and he published several pamphlets and larger treatises of Biblical criticism. Among his literary productions are a work on *The Mirroring of the Scripture the Old and New Testament*, 1856; *The Lord's Day the Day of the Lord*, 1869; a pamphlet on *The Ascension Sacrifice of the Old Testament*, 1864; and one on *The Royal Academy a National Institution*, 1869. A word should be said regarding Linnell's connexion with William Blake. He was one of the best friends and kindest patrons of the great visionary artist. He gave him the two largest commissions he ever received for single series of designs—£160 for drawings and engravings of *The Inventions to the Book of Job*, and a like sum for those illustrative of Dante.

LINNET, Anglo-Saxon *Linnet* and *Linnet-weige*, whence seems to have been corrupted the old Scottish "Luntquib," and the modern northern English "Lintwhite,"—originally a somewhat generalized bird's name, but latterly specialized for the *Pringilla cannabina* of Linnaeus, the *Linota cannabina* of recent ornithologists. This is a common and well-known song-bird, frequenting almost the whole of Europe south of lat. 64°, and in Asia extending to Turkestan. In Africa it is known as a winter visitant to Egypt and Abyssinia, and is abundant at all seasons in Barbary, as well as in the Canaries and Madeira. Though the fondness of this species for the seeds of flax (*Linum*) and hemp (*Cannabis*) has given it its common name in so many European languages,¹ it feeds largely, if not chiefly, in Britain on the seeds of plants of the order *Compositae*, especially those growing on heaths and commons. As these waste places have been gradually brought under the plough, and improved methods of cultivation have been applied to all arable land, in England and Scotland particularly, the haunts and means of subsistence of the Linnet have been slowly but surely curtailed, and hence of late years its numbers have undergone a very visible diminution throughout Great Britain, and its diminution has also been aided by the detestable practice of netting it in spring—for it is a popular cage-bird—so popular indeed as to require no special description. According to its sex, or the season of the year, it is known as the Red, Grey, or Brown Linnet,

and by the earlier English writers on birds, as well as in many localities at the present time, these names have been held to distinguish at least two species; but there is now no question among ornithologists on this point, though the conditions under which the bright crimson-red colouring of the breast and crown of the cock's spring and summer plumage is donned and doffed may still be open to discussion. Its intensity seems due, however, in some degree at least, to the weathering of the brown fringes of the feathers which hide the more brilliant hue, and it is to be remarked that in the Atlantic islands examples are said to retain their gay tints all the year round, while throughout Europe there is scarcely a trace of them visible in autumn and winter; but, beginning to appear in spring, they reach their greatest brilliancy towards midsummer; and it is also to be remarked that they are never assumed by examples in confinement. The Linnet begins to breed in April, the nest being generally placed in a bush at no great distance from the ground. It is nearly always a neat structure composed of fine twigs, roots, or bents, and lined with wool or hair. The eggs, often six in number, are of a very pale blue marked with reddish or purplish brown. Two broods seem to be commonly brought off in the course of the season, and towards the end of summer the birds—the young of course greatly preponderating in number—collect in large flocks and move to the sea-coast, whence a large proportion depart for more southern latitudes. Of these emigrants some return the following spring, and are invariably recognizable by the more advanced state of their plumage, the effect presumably of having wintered in countries enjoying a brighter and hotter sun.

Nearly allied to the foregoing species is the Twite, so named from its ordinary call-note, or Mountain-Linnet, the *Linota flavirostris*, or *L. montium* of ornithologists, which can be at once distinguished by its yellow bill, longer tail, and reddish-tawny throat. This bird never assumes any crimson on the crown or breast, but the male has the rump at all times tinged more or less with that colour. In the breeding-season it seems to affect exclusively hilly and moorland districts from Herefordshire northward, in which it partly or wholly replaces the common Linnet, but is very much more local in its distribution, and, except in the British Islands and some parts of Scandinavia, it only appears as an irregular visitant in winter. At that season it may, however, be found in large flocks in the low-lying countries, and as regards England even on the sea-shore. In Asia it seems to be represented by a kindred form, *L. brevirostris*.

The REDPOLS (*g.n.*) form a little group placed by many authorities in the genus *Linota*, to which they are unquestionably closely allied, but in this work they may be considered later; and, as before stated (FISCHER, vol. xi. p. 192), the Linnets seem on the other hand to be related to the birds of the genus *Leucosticte*, the species of which, in number uncertain, inhabit the northern parts of North-West America and of Asia. The most recent list of the birds of the former country by Mr Ridgway (*Bull. U. S. Nat. Museum*, No. 21, 1881) includes four species and one local race, of which there is need here to mention only *L. lephrocois*. It is generally of a chocolate colour, tinged on some parts with pale crimson or pink, and has the crown of the head silvery-gray. Another species, *L. arctos*, was formerly said to have occurred in North America, but its proper home is in the Kurile Islands or Kamchatka. This has no red in its plumage. The birds of the genus *Leucosticte* seem to be more terrestrial in their habit than those of *Linota*, perhaps from their having been chiefly observed where trees are scarce; but it is possible that the mutual relationship of the two groups is more apparent than real. Allied to *Leucosticte* is *Montifringilla*,

¹ E.g., French, *Linette*; German, *Hänfling*; Swedish, *Hänfling*.

to which belongs the Snow-Finch of the Alps, *M. nivalis*, so often mistaken by travellers for the Snow-Bunting, *Plectrophenax nivalis*.

LINOLEUM is a kind of floor-cloth, invented and introduced by Mr F. Walton, who in 1860 obtained a patent for its manufacture. It consists of a preparation of linseed oil and ground cork intimately mixed and spread in a uniform layer over a sheet of rough jute canvas. Under the name of kamptulicon, a material similar in appearance and properties, but in which prepared india-rubber took the place of oxidized linseed oil, was in use to a limited extent previous to the introduction of linoleum; the latter material, however, was found to possess several advantages; among others it had the merit of comparative cheapness as against kamptulicon, which it entirely supplanted. Linoleum also became a formidable competitor with the old form of oil floor-cloth, and on the expiry of Mr Walton's patent the manufacture of the new material was very generally taken up in Kirkcaldy, the principal seat of the floor-cloth trade. In the hands of Messrs Michael Nairn & Co., who were the first to introduce the floor-cloth industry into Scotland, the machinery used for making linoleum has been improved in important respects, and the ingenuity and resource of Mr Walton, the original patentee, have discovered several new adaptations and modifications of his original invention.

The making of linoleum involves three distinct preliminary operations—(1) the oxidation of the linseed oil, (2) the grinding of the cork, and (3) the weaving of the jute canvas backing. Of these operations the oxidation of the oil is the most peculiar and distinctive. The linseed oil is first boiled with litharge in the way practised for preparing ordinary boiled oil (see **LINSEED**), and it is next oxidized by exposure, in exceedingly thin films, to the influence of air. To secure the exposure of sufficient surfaces of oil to the atmosphere, a large lofty apartment is hung with sheets or continuous webs of calico cloth, which are allowed to depend from near the roof into troughs or tanks on the floor. These webs of calico are kept sufficiently far apart to allow free circulation of air between them. They are daily drenched with boiled oil by allowing it to trickle down from the top over their entire surface, the distribution being effected by a special arrangement of movable tanks and tubs. It will be seen that an enormous surface of oil can thus be exposed within a comparatively limited space. The influence of oxygen on the oil films is facilitated by the blowing of heated air into the chamber so as to keep up a continual circulation; and the activity of the process is unpleasantly manifested by the extremely acid odour which is evolved by the oil. Day by day the thickness of the coating of oxidized oil increases, and when a deposit of about half an inch has been accumulated, the drenching is stopped. The product, now ready for being withdrawn, forms firm translucent sheets of a countchou-like substance having a straw yellow colour, possessed of a certain amount of elasticity, and communicating no oily stain to paper. These sheets are now torn into small pieces and reduced to a uniform plastic mass by means of powerful crushing rollers, after which the material is placed in a close boiler with the addition of certain proportions of kauri gum, resin, and ochre, amber, or other pigment, according to the ground-colour desired. The boiler is heated by steam, and the entire mass, being thoroughly incorporated by means of stirrers, is run into a shallow trough, from which, after cooling and solidifying, it is taken in large slabs. These are piled up awaiting future use, and when required for manufacturing purposes they are cut into blocks about the size of an ordinary brick.

Ground cork, which is the second essential constituent of linoleum, may be made from cork cuttings and scraps;

but, the supply of such material being unequal to the demand, bala cork, of secondary quality as imported, is very largely used. It is first broken to pieces about the size of a nut, the fragments are fed into the hopper of a mill;

and the cork passes thence between a pair of ordinary millstones in which it is reduced to a meal-like condition, in exactly the same way as wheat is ground to flour. The product is sifted, and the insufficiently ground portions are returned to be passed again through the mill. In the grinding of the cork great care is necessary to prevent iron, stone, or other hard foreign material from getting into the mill, as such substances, causing sparks between the stones, readily give rise to explosions in air so laden with fine dust as that of the mill necessarily is.

In the making of the jute backing the only notable feature is the great width of the loom, in which webs 12 feet broad are woven by Messrs Nairn. The maximum width of that produced by other makers, however, has hitherto been 6 feet.

The actual preparation of linoleum floor-cloth in the factory of Messrs Nairn is conducted in a continuous series of operations by machinery which has been patented by that firm. The bricks of oxidized oil and the requisite proportion of cork are thrown into a hopper, where they are thoroughly mixed in a kind of pug mill, whence the mixture is shot forward in a tube, at the open end of which it is sliced off in thin crumbling masses by a revolving knife. Spread out in thin sheets, it passes from this between a series of steam-heated rollers, from the last of which it is scratched off by a circular drum covered with sharp steel points, and falls in a fine shower into a feeding box the whole width of the linoleum to be made. From this feeding box the mixture is uniformly delivered on the surface of the canvas, which here meets it, and passing immediately between powerful smooth rollers, the semi-plastic mixture is firmly squeezed on the surface of, and rendered adherent to, the rough open canvas which forms its back. The distance between the upper and lower compressing roller determines the thickness of the linoleum, three standard thicknesses being recognized, viz., $\frac{3}{8}$, $\frac{1}{2}$, and $\frac{5}{8}$ parts of an inch. Linoleum of the thickness of $\frac{1}{2}$ of an inch is also made for public libraries and reading-rooms on account of its perfect noiselessness. It only remains to coat or waterproof the raw canvas back with oil paint, and the floor-cloth is finished as plain linoleum. The printing of patterns in various colours on its surface is done as described under **FLOOR-CLOTH**, vol. ix. p. 329. Corticine is a form of linoleum, in which the oil is oxidized by chemical agents.

Recently a method of ornamenting linoleum with patterns in the form of tiles or tesserae, the colour of each tile going right through to the canvas or sufficiently deep for constant wear, has been devised and patented by Mr C. F. Leake. The patentee proposes to use canvas first covered with a thin linoleum coating. This he brings on a table on which are a series of moulds corresponding with the coloured tile pattern required. Into each mould is put the required quantity of properly-coloured granulated linoleum material, which is compressed into solid tiles by the descent of plungers. The part covered by the pattern is carried forward and powerfully squeezed between hydraulic rams, the tiles being thus made smooth, homogeneous, and firmly adherent, while in the meantime the moulds are being filled and a new set of tiles prepared in the first stage of the operation. Mr Walton, the original patentee of linoleum, has developed a preparation of oxidized oil and cork or other thickening material embossed with patterns for wall decorations under the name of "Lancaster Walton." (J. P.A.)

—**LINSEED** is the seed of the common flax or flint, *Linum catharticum*, from which also the well-known fibre flax is obtained. The plant itself is figured and described under **FLAX**, vol. ix. p. 263. The fruit of the flax plant consists of a globose capsule which splits into five cocci, each containing two seeds. These seeds, the linseed of commerce, are of a lustrous brown colour externally, and a

compressed and elongated oval form, with a slight beak or projection at one extremity. The brown testa contains, in the outer of the four coats into which it is microscopically distinguishable, an abundant secretion of mucilaginous matter; and it has within it a thin layer of albumen, enclosing a pair of large oily cotyledons. The seeds when placed in water for some time become coated with glutinous matter from the exudation of the mucilage in the external layer of the epidermis; and by boiling in sixteen parts of water they exude sufficient mucilage to form with the water a thick pasty decoction. The cotyledons contain the valuable linseed oil referred to below. Linseed grown in tropical countries is much larger and more plump than that obtained in temperate climes, but the seed from the colder countries, on the other hand, yields a finer quality of oil. Pluckiger and Hanbury found that six seeds of Sicilian linseed, thirteen of Black Sea, and seventeen of Archangel linseed weighed respectively one gram. The average composition of linseed may be fairly represented by the following analysis by Dr Thomas Anderson:—albuminous substances, 24.44; oil, 34.00; gum sugar and cellulose, 30.73; ash, 3.33; water, 7.50. Linseed is cultivated and secured as a crop in all European flax-growing countries, where the seed is probably not less valuable than the fibre. It is also obtained from Egypt and India, being cultivated in the latter country solely on account of the seed.

Apart from its value as a source of oil, and for sowing, linseed is not a product of much economic importance. It formed an article of food among the Greeks and Romans, and it is said that the Abyssinians at the present day eat it roasted. The oil is to some extent used as food in Russia, and in parts of Poland and Hungary. Linseed meal, partly on account of its bland oily constitution, is a valuable material for poultices. At one time the crushed seeds were the officinally recognized cataplasmic material, but the readiness with which that preparation became rancid through the oxidation of its abundant oil frequently rendered it a dangerous application for open sores. The *lini farina* of the pharmacopoeia is now the powdered meal of the cake left after expression of the oil, with a proportion of olive oil added when about to be used. An infusion of linseed under the name of "linseed tea" is a popular diluent in bronchial and other inflammatory affections. The abundant mucilage in linseed meal makes it a most useful material for luting stoppers in chemical jars, and other such joints in glass-work. Linseed cake, the marc left after the expression of the oil, is a most valuable feeding substance for cattle. According to a recent analysis by Dr Voelcker (*Journ. Roy. Agric. Soc.*, 2d ser., vol. xvii, p. 659) it contains in 100 parts—oil, 10.90; albuminous compounds, 24.56; mucilage, sugar, and digestible fibre, 31.97; woody fibre, 11.47; ash, 6.20; moisture, 14.90.

Linseed is subject to extensive and detrimental adulterations, resulting not only from careless harvesting and cleansing, whereby seeds of the flax dodder and other weeds and grasses are mixed with it, but also from the direct admixture of cheaper and inferior oil seeds, such as wild rape, mustard, sesame, poppy, &c., the latter adulterations being known in trade under the generic name of "beffum." In 1884, owing to the serious aspect of the prevalent adulteration, a union of traders was formed under the name of the "Linseed Association," the members of which bind themselves to give compensation for all adulterations in excess of 4 per cent. of foreign matter. Highly adulterated linseed is, however, still very common outside the field of operations of the Linseed Association.

The quantity of linseed imported into the United Kingdom during the year 1881 was 1,829,888 quarters, of a value of £4,595,051. About one-half of this amount, 927,059 quarters, valued at £2,249,877, came from the East Indies, and the imports from Russia, amounting to 728,953 quarters, valued at £1,664,720, account for the greater part of the remainder.

Linseed Oil, the most valuable and characteristic of the series of drying oils, is obtained by expression from the seeds, with or without the aid of heat. Preliminary to

the operation of pressing, the seeds are crushed between a pair of revolving rollers, and ground to a fine meal under heavy edge stones on a stone bed. For the extraction of the fine quality of oil known as cold-drawn the meal is, without further preparation, filled into woollen or canvas bags and enclosed in horse-hair envelopes for pressure, either in a Dutch mill worked by means of wedges and falling stampers or in a screw press, or, what is now more prevalent, in a special form of hydraulic press. The oil so obtained is of a clear yellow colour, and is comparatively devoid of odour and taste. The cake left by cold pressure is again ground up, heated in a steam kettle to about 212° Fahr., and while hot submitted to further pressure, which results in the exudation of a less pure oil of a brownish-yellow colour. In general practice, cold-drawn oil is little prepared; the linseed after grinding is submitted to a high heat, whereby the mucilage in the epidermis is destroyed, and the oil flows more freely; and in many crushing establishments the oil is obtained by a single operation under the press. The yield of oil from different classes of seed varies, but from 23 to 28 per cent. of the weight of the seed operated on should be obtained. A good average quality of seed weighing about 322 lb per quarter has been found in practice to give out 109 lb of oil.

Commercial linseed oil has a peculiar rather disagreeable sharp taste and smell; its specific gravity is given as varying from 0.928 to 0.963, and it does not solidify under the influence of very low temperature. It is soluble in 32 parts of alcohol, sp. gr. 0.82, in 6 parts of boiling alcohol, and in 1.6 of ether. By saponification it yields about 95 per cent. of fatty acids, principally linoleic acid ($C_{18}H_{32}O_2$), a body peculiar to the drying oils, and by treatment with oxide of lead about nine-tenths of the resulting lead salt is found to be linoleate of lead. The oil may be perfectly bleached by treatment with a solution of green sulphate of iron, with repeated shaking and exposure to the light for a period of four to six weeks. Exposed to the air in thin films, linseed oil absorbs oxygen and forms a resinous semi-elastic caoutchouc-like mass, oxynoleic acid, $C_{17}H_{30}O_2$. The oil, when boiled with small proportions of litharge and minium, undergoes the process of resinification in the air with greatly increased rapidity. Sacc found by boiling 2500 grains of raw oil for ten minutes with 30 grains each of litharge and minium, and weighing after twenty-four hours exposure to the atmosphere, that the oil had lost only 60 grains. A second sample he boiled till there was a loss of 5 per cent. in weight, when the product assumed the consistency of molasses; and a third portion boiled to a loss of 12 per cent. became a caoutchouc-like mass. The first of these products he found dried, on exposure, to a fine transparent varnish; the second did not resinify after fifteen days' exposure; and the atmosphere had no effect on the third portion. The weight of the film of the first after complete resinification was increased 50 per cent. through absorption of oxygen, and the rate at which absorption took place was much influenced by heat.

To these physical properties the varied industrial applications of linseed oil are principally due. Its most important use is certainly found in the preparation of oil paints and varnishes. By painters both raw and boiled oil are used, the latter not only forming the principal medium in oil painting, but also serving separately as the basis of all oil varnishes. Boiled oil is prepared in a variety of ways—that most common being by heating the raw oil in an iron or copper boiler, which, to allow for frothing, must only be about three-fourths filled. The boiler is heated by a furnace, and the oil is brought gradually to the point of ebullition, at which it is maintained for two hours, during which time moisture is driven off, and the sassa and froth which accumulate on the surface are led out. Then by slow degrees a proportion of "dryers" is added—usually equal weights of litharge and minium being used to the extent of 8 per cent. of the charge of oil; and with these a small proportion of amber is generally thrown in. After the addition of the dryers the boiling is continued two or three hours;

the fire is then suddenly withdrawn, and the oil is left covered up in the boiler for ten hours or more. Before sending out, it is usually stored in settling tanks for a few weeks, during which time the uncombined dryes settle at the bottom as "floats." Besides the dryes already mentioned, acetate of lead, beate of manganese, binucle of manganese, sulphate of zinc, and other bodies are used. The theory of the influence of boiling and of the addition of these bodies on lincos oil is not well understood. By lincos it was suggested that they simply removed the mangalicious and other foreign constituents of the oil which by their presence interrupted the action of oxygen, but by Chevalier and others the opinion was held that the chemicals used, by giving up oxygen to the oil, thereby induce a more rapid and energetic absorption from the air. However this may be, it does not appear at least that boiling is essential for the production of that active condition of the oil, as it may also be induced by treatment of cold raw oil with lead acetate and other agencies. Boiled oil is now very largely used in the manufacture of lincos floor-cloth. See LINCOS.

Lincos oil is also the principal ingredient in painting and lithographic inks. The oil for ink-making is prepared by heating it in an iron pot up to the point where it takes lincos fire spontaneously or can be ignited with any flaming substance. After the oil has been allowed to lincos for some time according to the consistency the warmth desired, the pot is covered over, and the product when cooled forms a viscid, tenacious substance which in its most concentrated form may be drawn into threads. By boiling this viscus with dilute nitric acid vapours of acrolein are given off, and the substance gradually becomes a solid non-adhesive mass the same as the ultimate oxidation product of both raw and boiled oil.

Lincos oil is subject to various falsifications, chiefly through the addition of cotton-seed, rape-seed, and hemp-seed oils, and iron oil and mineral oils also are not infrequently added. Except by smell, by change of specific gravity, and by determination of drying properties, these falsifications are difficult to detect. (J. F. A.)

LINUS is one of a numerous class of heroe figures in Greek legend, of which other examples may be found under HYACINTHUS, ADONIS. The connected legend is always of the same character: a beautiful youth, fond of hunting and rural life, the favourite of some god or goddess, suddenly perishes by a terrible death in spite of the heavenly love that would fain protect him. In some cases nothing is known to us with certainty beyond the mythological figure, but in many cases the religious background from which the legend stands out in relief has been preserved to us; in such cases we see that an annual ceremonial, everywhere of the same enthusiastic character, commemorated the legend. At Argos this religious character of the Linus myth was best preserved. The secret child of Psamathe by the god Apollo, Linus is exposed, nursed by sheep, and torn in pieces by the sheep-dogs. Every year in the festival *Amis* or *Cynophontis*, the women of Argos mourned for Linus and propitiated Apollo, who in revenge for his child's death had sent a plague on the Argive children. The grave of Linus, like that of Hyacinthus at Amyclae, was shown at Argos, at Thebes, at Chalcis, and probably at other places. The enthusiasm and *abandon* which characterized the similar festivals over Greece, Asia Minor, and Syria prove that it was part of the nature worship which spread in various forms by different roads and at different periods from the East into Greece. The songs of lamentation which accompanied the festival strongly impressed the Greeks, and it is most probable that the Phoenician words *as lena*, *as lena*, which formed the burden of the Adonis songs, originated the Greek words *Linus* and *Adonis*. The Linus song is frequently mentioned in Greek literature, Homer, *Il.*, xviii. 569, Pind., *Fr.* 139 (Bergk), &c., the tragic poets often use the word *Adonis* as the refrain in mournful songs, and Euripides calls the custom Phrygian (*Or.* 1380). In Phrygia the mythic correspondent of Linus is called *Lutyses*. There can be no doubt that Linus, Adonis, Menenius, Narcissus, &c., are personifications of the life and bloom of nature suddenly slain by the hot sun of summer, while with the religious mourning over the catastrophe of nature were intertwined the ideas of life in relation to death, of good and evil, and so on. The religious side of the Linus myth seems hardly to have

existed in Greece outside of Argos; in Thebes, which also was a chief home of the legend, Linus was a hero of song and music. In this form he has passed into literature, e.g., Virgil, *Ed.*, vi. 67. He is conceived as the inventor of musical methods, especially of the *Opispos*, a kind of lament; this idea was expanded in various ways, particularly by the Alexandrian poets, and finally he was, after the analogy of Musaeus, transformed into a composer of prophecies and legends.

See Duguchi, *Die Adonis Klage* und des Linos Lied, &c.

LINUS, one of the saints of the Gregorian canon, was, according to the *Breviarium Romanum*, the immediate successor of Peter in the see of Rome. He was a native of Volterra, who had attained a high degree of sanctity, and by his prevailing faith was able, not only to cast out devils, but to raise the dead. He wrote an account of the *res gestae* of Peter, especially of his controversy with Simon Magus.

He was beheaded by the orders of the ungrateful consul Saturninus, whose daughter he had freed from demonic possession, after a pontificate of eleven years two months and twenty-three days. The authorities for the statement that Linus was leaving Peter out of account, the earliest president of the Roman Church, are very early (Irenaeus, *Adv. Haer.*, iii. 3, 3; Euseb., *H. E.*, iii. 2, 13), and that these actually was a presbyter of that name may be gathered from 2 Tim. iv. 21. According to Tertullian, however (*De Praxico*, 32), Peter appointed Clement to be his successor. The genuineness of the alleged epitaph of Linus found in Rome is now no longer maintained, and the two books on the martyrdom of Peter and Paul, which pass under his name, must therefore be regarded as apocryphal and late.

LINZ, capital of Upper Austria, and see of a bishop, in 48° 19' N lat., 14° 16' E. long., lies upon the right bank of the Danube, 88 miles west of Vienna, at the junction of the Kaiserin-Elizabeth Western Railway with a line from Prague and Budweis. The market-town of Urfaulr, on the opposite side of the river, is connected with the city

by an iron bridge 700 feet in length, constructed in 1873. Linz possesses two cathedrals, one dating from 1670, and another, dedicated to the Immaculate Conception, commenced in 1802, and still unfinished, a Lutheran (1846) and several Roman Catholic churches, the new synagogue opened in 1877, and many religious houses. The old

Landeshaus, or House of the Estates (1562), the Bibliotheca Publica (1768), now (1832) containing 34,000 volumes, the Museum Francisco-Carolinum (1834), and a state theatre (1803) may also be noticed, with the episcopal and archiepiscopal palaces, and the castle now used as barracks. There are many educational establishments, including the theological diocesan lyceum, a new gymnasium and normal schools, and several hospitals and asylums. The principal manufactures are of tobacco (in 1880 employing 787 hands, and producing 23,266,000 cigars and 1850 tons of tobacco), and boot-varnish and blacking (2500 cwt.), the last chiefly exported to Hungary and Italy. Two breweries in 1881 produced 1,781,328 gallons of beer, and the other industries include iron-boat-building, and the manufacture of locomotives and agricultural implements. Trade and commerce are facilitated by the river. About forty-six thousand passengers embark or disembark at the steamboat landing stage, and the imports and exports there amount together to about 600,000 cwt. annually. There is a considerable traffic in woollen goods, carpets, linen fabrics, thread, prepared leather, iron wares, and salt. Cattle and meat markets are held twice a week. The Volkfest, a popular fair held generally every second September, is much resorted to by strangers. The surrounding country is highly picturesque. On the 31st December 1880 the population (exclusive of the garrison, 2799) was 36,116, or with the suburbs of Waldegg (1204) and Lustenau (1668) 38,888, chiefly Roman Catholics.

Linz is believed to stand on the site of the Roman station *Lentium* or *Lentia*. The authentic history of Linz cannot be traced further back than 799. In 1140 it was purchased from Gottschalk, count of Kyrburg, by Leopold IV., margrave of Austria, in 1524 it first received municipal rights, and in 1490 became the capital of the province above the Enns. Of various attacks which Linz from time to time successfully resisted the most notable was that by the insurgent peasants under Stephen Fadinger, 21st and 22d July 1626, when the suburbs were laid in ashes. As Linz (18th December 1645) peace was concluded between the emperor Ferdinand III. and the Transylvanian prince Rákóczy (see HUNGARY, vol. xii p. 370). During the siege of Vienna in 1688 the castle at Linz was the residence of Leopold I. The triple deliverance of Linz from fire, and pestilence was commemorated by Charles VI., in 1725, by the erection of a marble monument known as Trinity Column. In 1741, during the war of the Austrian succession, Linz was taken by the troops of the elector of Bavaria, but on the 23d January 1742 it was recovered by the Austrians. The bishopric was established by Pope Pius VI. in 1784. On the 15th of August 1800 many of the principal buildings were destroyed by fire. On the 17th May 1809 an Austrian force was defeated near the city in an engagement with Saxon and Wurtemberg troops. The chain of outlying forts, thirty-two in number, now abandoned, and to a great extent demolished, was constructed between 1823 and 1838 under the direction of Archduke Maximilian d'Este. A general assembly of the Catholic Union for Germany was held here 24th to 26th September 1850. Tramways were introduced in 1880, and a new line of railway through the Kremsthal was completed as far as Kremsmünster in 1881.

See the anonymous *Führer auf der Kremsthalbahn, mit Beschreibung von Linz, Linz, 1881*, the *Statistische Bericht über Österreich von Linz, 1881*, vol. ii p. 248-253; the official *Ergebnisse über die Volkszählung in Linz, Linz, 1881*; F. Kerschbamer, *Die Geschichte von Linz, Linz, 1876*, and G. H. Helm, *Linz und seine Umgebungen*, 2d ed., Linz, 1888.

LION. From the earliest historic times few animals have been better known to man than the lion. Its geographical habitat made it familiar to all the races among whom human civilization took its origin, and its strongly marked physical and moral characteristics have rendered it proverbial, perhaps to an exaggerated degree, and have in all ages afforded favourite types for poetry, art, and heraldry.

The literature of the ancient Hebrews abounds in allusions to the lion; and the almost incredible numbers that are stated to have been provided for exhibition and destruction in the Roman amphitheatres (as many as six hundred on a single occasion by Pompey, for example) show how abundant these animals must have been within accessible distance of the capital of the world.

The geographical range of the lion was once far more extensive than at present, even within the historic period covering the whole of Africa, the south of Asia, including Syria, Arabia, Asia Minor, Persia, and the greater part of northern and central Hindustan, and also the south-eastern portion of Europe, as shown by the well-known story told by Herodotus of the attacks by lions on the camels which carried the baggage of the army of Xerxes on its march through the country of the Thracians in Macedonia. The very circumstantial account of Herodotus shows that the animal at that time ranged through the country south of the Balkans, through Roumania to the west of the river Caran, and through Thessaly as far south as the Gulf of Lepanto and the Isthmus of Corinth, having as its western boundary the river Potamo and the Pindus mountains. The whole of the evidence relating to the existence of lions in Europe, and to their retreat from that continent shortly before the commencement of the Christian era, has been collected in the article on "*Felis spelæa*" in Boyd Dawkins and Sanford's *British Pleistocene Mammalia*, 1868. Fossil remains attest a still wider range, as it is shown in the same work that there is absolutely no osteological or dental character by which the well-known cave lion (*Felis spelæa* of Goldfuss), so abundantly found in cave deposits of the Pleistocene age, can be distinguished from the existing *Felis leo*. There are also remains found in North America of an animal named *Felis atrox* by Leidy, which the paleontologists just quoted attribute to the common lion; but, as they are very fragmentary, and as the specific characters by which most of the *Felidae* are distinguished are more dependent on external than on anatomical conformation, this determination cannot be so absolutely relied upon.

At the present day the lion is found in localities suitable to its habits, and where not exterminated (as it probably was in Europe) by the encroachments of man, throughout Africa from Algeria to the Cape Colony, and in Mesopotamia, Persia, and some parts of the north-west of India. According to Blanford, lions are still very numerous in the reedy swamps bordering the Tigris and Euphrates, and also occur on the west flanks of the Zagros mountains and the oak-od ranges near Shiraz, to which they are attracted by the immense herds of swine which feed on the acorns. The lion nowhere exists in the table-land of Persia, nor is it found in Baluchistan. In India it appears now to be confined to the province of Kathiawar in Gujerat, though within the present century its range extended through the north-west parts of Hindustan, from Bahawalpur and Sind to at least the Jumna (about Delhi), southward as far as Khândesh, and in Central India through the Sagur and Nerbudda territories, Bundelkhand, and as far east as Palamau. It was extirpated in Harijána about 1824. One was killed at Rhyli, in the Dumah district, Sagur and Nerbudda territories, so late as in the cold season of 1847-48; and about the same time a few still remained in the valley of the Sind river in Kotah, Central India (Blyth).

The great variations in external characters which different lions present, especially in the colour and the amount of mane, has given rise to the idea that there are several species, or at all events distinct varieties peculiar to different localities. It was at one time supposed, on the authority of Captain Walter Smee,² that the lion of Gujerat differed essentially from that of Africa in the absence of mane, but subsequent evidence has not supported this view, which was probably founded upon young specimens having been mistaken for adults. Lions from that district as well as from Babylonia, which have lived in the gardens of the London Zoological Society, have had as

¹ *Zoology and Geology of Eastern Persia*, 1876.

² *Transactions of the Zoological Society*, vol. i. p. 135, 1838.

fully developed manes as any other of the species. Mr F C Selous¹ has shown that in South Africa the so-called black-maned lion and others with yellow scanty manes are found, not only in the same locality, but even among individuals of the same parentage.

The lion belongs to the very natural and distinctly defined group constituting the genus *Felis* of Linnæus (for the characters and position of which see article MAMMALIA), a genus held by Pallas and other philosophical naturalists as a model of what a genus ought to be, although recent writers have divided and subdivided it into as many as thirteen sections, on each of which a new generic term has been imposed. Among these sections is one containing the largest members of the group, and differing from the others in the well-marked anatomical character that the anterior cornu of the hyoid arch is but little ossified, and by the less important one that the pupil of the eye when contracted is a circular hole, instead of a vertical slit as in the cat. The lion agrees with the tiger and the leopard in these respects, but differs from them in its uniform style of colouring, and from all the other *Felids* in the arrangement of its hairy covering, the hair of the top of the head, chin, and neck, as far back as the shoulder, being not only very much longer, but also differently disposed from the hair elsewhere, being erect or directed forwards, and so constituting the characteristic ornament called the mane. There is also a tuft of elongated hairs at the end of the tail, one upon each elbow, and in most lions a copious fringe along the

FIG 1—Lion and Lioness, after a Drawing by Wolf in Elliot's Monograph of the *Felids*

middle line of the under surface of the body, wanting, however, in some examples.² It must, however, be observed that these characters are peculiar to the adults of the male sex only, and that, even as regards their coloration, young lions show indications of the darker stripes and mottlings so characteristic of the greater number of the members of the genus, just as the young of nearly all the

plain-coloured species of deer show for a time the light-coloured spots which are met with in the adults of only some of the species. The usual colour of the adult lion is yellowish-brown, but it may vary from a deep red or chestnut brown to an almost silvery grey. The mane, as well as the long hair of the other parts of the body, sometimes scarcely differs from the general colour, but it is usually darker and not unfrequently nearly black. The mane begins to grow when the animal is about three years old, and is fully developed at five or six.

In size the lion is only equalled or exceeded by the tiger among the existing *Felids*, though both species present great variations, the largest specimens of the latter appear to surpass the largest lions. A full-sized South African lion, according to Selous, measures slightly less than 10 feet from nose to tip of tail, following the curves of the body. Haris gives 10 feet 6 inches, of which the tail occupies 3 feet. The lioness is about a foot less.

The internal structure of the lion, except in slight details, resembles that of the other *Felids*, the whole organization being that of an animal modified to fulfil, in the most perfect degree yet attained, an active, predaceous mode of existence. The teeth especially exemplify the carnivorous

FIG 2—Front View of Skull of Lion

type in its highest condition of development. The most important function they have to perform, that of seizing and holding firmly animals of considerable size and strength, violently struggling for life, is provided for by the great, sharp-pointed, and sharp-edged canines, placed wide apart at the angles of the mouth, the incisors between them being greatly reduced in size and kept back nearly to the same level, so as not to interfere with their action. The jaws are short and strong, and the width of the zygomatic arches, and great development of the bony ridges on the skull, give ample space for the attachment of the powerful muscles by which they are closed. In the molar series of teeth the sectorial or scissor-like cutting function is developed at the expense of the tubercular or grinding, there being only one rudimentary tooth of the latter form in the upper jaw, and none in the lower. They are, however, sufficiently strong to break bones of large size. The dental formula is expressed as follows—incisors 3, canines 1, premolars 3, molars 4 = 16; total, 30. The tongue is long and flat, and remarkable for the development of the papillæ of the anterior part of the dorsal surface, which (except near the edge) are modified so as to resemble long, compressed, recurved, horny spines or claws, which, near the middle line, attain the length of one-fifth of an inch. They give the part of the tongue on which they occur the appearance and feel of a coarse rasp, and serve the purpose of such an instrument in cleaning the flesh from the bones of the animals on which the lion feeds. The vertebral

¹ A Hunter's Wanderings in Africa, 1881, p. 256.

² Mr Selous, whose opportunities for obtaining evidence upon this subject were very large, says that in the region of South Africa, between the Zambezi and the Limpopo rivers, he never saw a lion with any long hair under the body, and that the manes of the wild lions of this district are far inferior in development to those commonly seen in menageries in Europe.

column is composed of seven cervical, thirteen dorsal, seven lumbar, three sacral, and about twenty-six caudal vertebrae. The clavicles are about 3 inches in length, embedded loosely in the muscles, and not directly connected either with the sternum or the scapula. The limbs are digitigrade, the animal resting upon round soft pads or cushions covered with thick, naked skin, one on the under surface of each of the principal toes, and one larger one of trilobed form, behind these, under the lower ends of the metacarpal and metatarsal bones, which are placed nearly vertically in ordinary progression. The fore feet have five toes, of which the third and fourth are nearly equal and longest, the second being slightly and the fifth considerably shorter. The first or pollex (corresponding to the human thumb) is much shorter than the others, and does not reach to the ground in walking. The hind feet have only four toes, the third and fourth being the longest, the second and fifth somewhat shorter and nearly equal. The first or hallux (or great toe) is represented only by a rudimentary metatarsal bone. The claws are all very large, strongly compressed, very sharp, and exhibit the retractile condition in the highest degree, being drawn backwards and upwards into a cutaneous sheath by the action of an elastic ligament so long as the foot is in a state of repose, but exerted by muscular action when the animal strikes its prey. By this remarkable piece of animal mechanism their edges and points are always kept sharp and un worn.

The habits of the lion in a state of nature are fairly well known from the united observations of numerous travellers and sportsmen who have explored those districts of the African continent in which it is still common. It lives chiefly in sandy plains and rocky places interspersed with dense thorn-thickets, or frequents the low bushes and tall rank grass and reeds that grow along the sides of streams and near the springs where it lies in wait for the larger herbivorous animals on which it feeds. Although it is occasionally seen abroad during the day, especially in wild and desolate regions, where it is subject to but little molestation, the night is, as in the case of so many other predaceous animals, the period of its greatest activity. It is then that its characteristic roar is chiefly heard, as thus graphically described by Gordon Cumming:—

"One of the most striking tones connected with the lion is his voice, which is extremely grand and peculiarly striking. It consists at times of a low deep moaning, repeated five or six times, ending in faintly audible sighs; at other times he startles the forest with loud, deep-toned, solemn roars, repeated in quick succession, each increasing in loudness to the third or fourth, when his voice dies away in five or six low muffled sounds very much resembling distant thunder. At times, and not infrequently, a troop may be heard, roaring in concert, one assuming the lead, and two, three, or four more regularly taking up their parts, like persons singing a catch. Like our Scottish stag at the rutting season, they roar loudest in cold frosty nights; but on no occasions are their voices to be heard in such perfection, or so intensely powerful, as when two or three troops of strange lions approach a fountain to drink at the same time. When this occurs, every member of each troop sounds a bold roar of defiance at the opposite parties, and when one roars, all roar together, and each seems to vie with his comrades in the intensity and power of his voice. The power and grandeur of these nocturnal concerts is inconceivably striking and pleasing to the hunter's ear."

"The usual pace of a lion," C. J. Andersson¹ says, "is a walk, and, though apparently rather slow, yet, from the great length of his body, he is able to get over a good deal of ground in a short time. Occasionally he trots, when his speed is not inconsiderable. His gallop—or rather succession of bounds—is, for a short distance, very fast,—nearly or quite equal to that of a horse. Indeed, unless the steed has somewhat the start when the beast charges, it will be puzzled to escape. Many instances are on record of horsemen who have incautiously approached too near to

the lion, prior to firing, who have been pulled down by him before they could get out of harm's way. Happily, however, the beast soon tires of the exertion of galloping, and unless his first succeeds he, for the most part, soon halts and beats a retreat." "The lion, as with other members of the feline family," the same writer tells us, "seldom attacks his prey openly, unless compelled by extreme hunger. For the most part he steals upon it in the manner of a cat, or ambushes himself near to the water, or a pathway frequented by game. At such times he lies crouched upon his belly in a thicket until the animal approaches sufficiently near, when, with one prodigious bound, he pounces upon it. In most cases he is successful, but should his intended victim escape, as at times happens, from his having miscalculated the distance, he may make a second or even a third bound, which, however, usually prove fruitless, or he returns disconcerted to his hiding-place, there to wait for another opportunity." His food consists of all the larger herbivorous animals of the country in which he resides,—buffaloes, various kinds of antelopes, zebras, giraffes, or even young elephants or rhinoceroses, though the adults of these latter he dare not attack. In cultivated districts the cattle, sheep, and even human inhabitants are never safe from his nocturnal ravages. He appears, however, as a general rule, only to kill when hungry or attacked, and not for the mere pleasure of killing, as with some other carnivorous animals. He, moreover, by no means limits himself to animals of his own kind, but, according to Selous, often prefers eating game that has been killed by man, even when not very fresh, to taking the trouble to catch an animal himself. All books of African travel and sport abound with stories, many of which are apparently well authenticated, of the lion's prodigious strength, as exemplified by his being able to drag off a whole ox in his mouth to a long distance, even leaping fences and dykes with it.

The lion appears to be monogamous, a single male and female continuing attached to each other irrespectively of the pairing season. At all events the lion remains with the lioness while the cubs are young and helpless, and assists in providing her and them with food, and in educating them in the art of providing for themselves. The number of cubs at a birth is from two to four, usually three. They are said to remain with their parents till they are about three years old. The following account by an eyewitness gives a good idea of lion family life:—

"I once had the pleasure of, unobserved myself, watching a lion family feeding. I was encamped on the Black Umfolosi in Zululand, and towards evening, walking out, about half a mile from camp, I saw a herd of zebra galloping across me, and when they were nearly 200 yards off, I saw a yellow body flash towards the leader, and saw him fall beneath the lion's weight. There was a tall tree about 60 yards from the place, and anxious to see what went on, I stalked up to it, while the lion was still too much occupied to look about him, and climbed up. By this time quite killed the beautifully striped animal, but instead of proceeding to eat it, he got up and roared vigorously, until there was an answer, and in a few minutes a lioness, accompanied by four whelps, came trotting up from the same direction as the zebra, which no doubt she had been to drive towards her husband. They formed a fine picture, as they all stood round the carcass, the whelps tearing it and biting it, but unable to get through the tough skin. Then the lion lay down, and the lioness driving her offspring before her did the same 4 or 5 yards off, upon which he got up, and commencing to eat, had soon finished a hind-leg, retiring a few yards on one side as soon as he had done so. The lioness came up next and tore the carcass to shreds, bolting huge mouthfuls, but not objecting to the whelps eating as much as they could find. There was a good deal of snarling and growling among these young lions, and occasionally a stand-up fight for a minute, but their mother did not take any notice of them, except to give them a smart blow with her paw if they got in her way. . . . There was now little left of the zebra but a few bones, which hun-

¹ *The Lion and the Elephant*, 1878, p. 19.

² Hon. W. H. Drummond, *The Large Game and Natural History of South and South-East Africa*, 1875, p. 278.

died of vultures were circling round waiting to pick, while almost an equal number hopped awkwardly about on the ground within 50 or 60 yards of it, and the whole lion family walked quietly away, the lioness leading, and the lion, often turning his head to see that they were not followed, bringing up the rear.

Though not strictly gregarious, lions appear to be sociable towards their own species, and often are found in small troops, sometimes consisting of a pair of old lions, with their nearly full-grown cubs, but occasionally of adults of the same sex; and there seems to be good evidence that several lions will associate together for the purpose of hunting upon a preconceived plan. As might be supposed, their natural ferocity and powerful armature are sometimes turned upon one another, combats, often mortal, occur among male lions under the influence of jealousy; and Andersson relates an instance of a quarrel between a hungry lion and lioness over the carcase of an antelope which they had just killed, and which did not seem sufficient for the appetite of both, ending in the lion not only killing, but even devouring his mate. Old lions, whose teeth have become injured with constant wear, often become "man-eaters," finding their easiest means of obtaining a subsistence in lurking in the neighbourhood of villages, and dashing into the tents at night and carrying off one of the sleeping inmates. Lions differ from most of the smaller *Felida* in never climbing trees, indeed, as mentioned before, they are rarely found in forests.

With regard to the character of the lion, those who have had opportunities of observing it in its native haunts differ greatly. The exaggerated accounts of early writers as to its courage, nobility, and magnanimity have led to a reaction, which causes some modern authors to speak of it in language quite the reverse, and to accuse it of positive cowardice and all kinds of meanness. Livingstone goes so far as to say, "nothing that I ever learned of the lion could lead me to attribute to it either the ferocious or noble character ascribed to it elsewhere," and he adds that its roar is not distinguishable from that of the ostrich. Of course these different estimates depend to a great extent upon the particular standard of the writer, and also upon the circumstances that lions, like other animals, undoubtedly show considerable individual differences in character, and behave differently under varying circumstances. They are certainly not so reckless as to be entirely devoid of the instinct of self-preservation, and if one, perhaps satiated with a good meal the night before, unexpectedly disturbed in the day time, will occasionally retreat when confronted, even by an unarmed man, that is scarcely a reason for assigning cowardice as one of the characteristics of the species. The latest authority, Selous, while never denying the daring courage of the lion when hungry or provoked, and vindicating the awe-inspiring character of the roar of several lions in unison, when heard at close quarters, as the grandest sound in nature, says with regard to its outward aspect:—

"It has always appeared to me that the word 'majestic' is singularly inapplicable to the lion in its wild state, as when seen by daylight he always has a stealthy furtive look that entirely does away with the idea of majesty. To look majestic a lion should hold his head high. Thus he seldom does. When walking he holds it low, lower than the line of his back, and it is only when he first becomes aware of the presence of man that he sometimes raises his head and takes a look at the intruder, usually lowering it immediately, and trotting away with a growl. When at bay, standing with open mouth and glaring eyes, holding his head low between his shoulders, and keeping up a continuous low growling, twitching his tail the while from side to side, no animal can look more unpleasant than a lion, but there is then nothing majestic or noble in his appearance."

Notwithstanding this evidently truthful description of the animal when seen under what may be called unfavourable circumstances, no one with an eye for beauty can contemplate the form of a fine specimen of a lion, at all

events in a state of repose, even though in the confinement of a menagerie, without being impressed with the feeling that it is a grand and noble-looking animal. (W. H. F.)

LIPARI ISLANDS. These islands, which take their name from the largest and most populous member of the group, are situated to the north of the eastern half of Sicily, between 38° 20' and 38° 55' N. lat., and 14° 15' and 15° 15' E. long. The seven principal islands are Lipari, Salina, Vulcano, Stromboli, Panara, Filicudi, and Alicudi; besides which there are ten islets, some of them mere rocks, the remains of a great central volcano now submerged. The total population of the islands in 1871 was 18,400, and the area is less than 50 square miles. They were known to the ancients as the *Hephestiades* or *Vulcani insulae*, from their supposed connexion with Vulcan, the *Liparenæ*, from their mythical king Lipara, and the *Æolus insulae*, from Æolus, who was said to have married the daughter of Lipara, and to have succeeded to the kingdom. Lipara, the chief island, was colonized in the 6th century B.C. by Onidians and Rhodians, who rapidly spread to the adjacent islands of Hiera and Didyma. The new settlers maintained their independence in spite of the attacks of the Tyrrhenian pirates, but they later became subject successively to the Athenians, Carthaginians, and Romans. In the Middle Ages the Saracens took possession of the islands, but they were expelled by the Normans in the 11th century. Finally Ferdinand the Catholic annexed them to Sicily.

Lipari has an area of about 11 square miles, with a population of 12,000. It is mountainous in character, and consists of tuffs and lavas, and of highly siliceous volcanic products such as quartz-trachyte, pumice, and obsidian. The great central cone, Monte Sant' Angelo (1952 feet), is the ruin of an extinct volcano, as is also Monte Chirica (1978 feet), while Campo Bianco or Monte Pelato (1500 feet) is a mountain of white pumice, breached by an outflow of vitreous lava. Hot springs exist in various parts of the island, the most important being those of San Calogero, mentioned by Diodorus Siculus, and situated about 6 miles from the town. The water, which possesses a temperature of 198° Fahr., contains free carbonic acid and sulphuretted hydrogen, together with carbonates of calcium and magnesium, and chlorides of calcium and sodium. The chief town, which stands on the eastern point of the island, is quite modern, and contains no objects of interest. The cathedral and several other churches are within the precincts of the castle, and they are presided over by a bishop and thirty-two canons. The castle is used as a prison for some four hundred malefactors, sent from various parts of Italy. The island is governed by a delegate, subject to the prefect of Messina. The soil is fertile, and a considerable trade is carried on by a number of merchants who export currants, figs, pumice stone, and malmsey wine. Water is scarce owing to the great porosity of the soil.

Six miles to the south of Lipari is the island of Vulcano, anciently known as *Hiera*, *Vulcania*, and *Thersia*. In early times it was a very active volcano; and it is described by Thucydides, Aristotle, and Callias as being frequently in a state of violent eruption. In the 3d century B.C. the smaller island of Vulcanoello was upheaved from the sea. The present crater was probably formed during the eruption of 1786, from which time the volcano remained in a quiescent state till the autumn of 1873, when it commenced to discharge clouds of vapour, showers of sand, and large stones. Blue and green flames were also seen to issue from rifts in the floor of the crater. When visited by the writer in 1879, the volcano had again relapsed into the solfatare stage, and it had recently been purchased by a Scotch firm for £8000, for the purpose of extracting alum, boracic

acid, and sulphur from the numerous products which line the sides and cover the floor of the crater. A number of volcanic minerals have been obtained from Vulcano; the most remarkable perhaps was that lately analysed by Professor Cosca of Turin, which was found to contain seven non-metallic elements and eight metals, among them the rare bodies thallium, cesium, and rubidium. The highest point of Vulcano—a portion of the old crater ring—has an altitude of 1601 feet.

A little more than 20 miles to the north-north-east of Lipari, the cone of Stromboli rises from the sea to a height of 3022 feet. It is of special interest to the vulcanologist from the fact that it is the only example in Europe of a volcano in a state of constant activity, and also because, from an elevated point above the crater (which is at the side of the cone below the summit), it is possible, when the wind blows away from the observer, to sit for hours and watch the operations going on within the crater. Such observations, carried out in 1783 by Spallanzani, made him the father of modern vulcanology, and furnished some of the most important data upon which the science is founded. The mountain is mentioned as early as the 4th century A.C.

Between Stromboli and Lipari there is a group of islets representing portions of the crater ring of a great volcano, the largest of which, *Panara (Fisera)*, is 7 miles in circuit, and contains about 200 inhabitants. It produces wheat, oil, and wine. *Salina (Diaplia)*, 3 miles to the north-west of Lipari, has an area of 10 square miles, and consists of two volcanic cones rising respectively to the height of 3185 and 2821 feet. The island contains nearly 6000 inhabitants, who are mainly employed in cultivating the vines, which produce a fine malvasia wine. The cone of *Pilichou* rises to a height of 2698 feet, some 10 miles to the west of Salina, while at an equal distance further west is *Alonchi*, the most westerly member of the Lipari group. It is partly cultivated, and is inhabited by about 500 fishermen and shepherds.

Good maps of the Lipari Islands have been published by the Italian Government. The best general account of the islands is still that of Admiral Smyth (*Italy and its Islands*, 1824), while Professor J. W. Judd has exhaustively discussed their geology in the pages of the *Geological Magazine* for 1876. (G. F. R.)

LIPETSK, a district town of Russia, in the government of Tamboff, 95 miles west of the chief town of the government, and 23 miles north-west of Gryazi railway junction, at the confluence of Lyssnoy Voronezh and Lipovka rivers. The town is built of wood, and the streets are unpaved, but it is a commercial centre of some importance. There are several beetroot-sugar and leather works, tallow melting houses, and distilleries. There is a brisk business at the weekly fairs, and the merchants carry on active trade in horses, cattle, tallow, skins, and honey, sent by rail to the northern provinces, and in timber, shipped down to the province of the Don Cossacks. The Lipetsk mineral springs came into repute in the time of Peter I., who caused them to be surrounded by galleries, and laid down three gardens; they continue to attract visitors during the summer. Lipetsk received municipal institutions in 1779. Population 14,500.

LIPPE is the name of a territory in north-western Germany, now divided into two small sovereign principalities, but formerly united under the same ruler. The name is derived from the river Lippe, which rises in the Teutoburgian Forest, and flows into the Rhine at Wesel.

LIPPE proper, also called **LIPPE-DIEMOLD**, is bounded on three sides by the Prussian province of Westphalia, and on the E. and N.E. by Hanover, Pyrmont, and Hesse-Cassel. It also possesses three small enclaves in Westphalia. Its area is about 450 square miles. The greater part of the surface is mountainous, especially towards the south, where it is intersected by the Teutoburgian Forest. The chief rivers are the Weser, which crosses the north extremity of the principality, and its affluents the Werre, Exter, Kalle, and Emmer. The forests of Lippe are among the finest in Germany, and

produce abundance of excellent timber. The valleys contain a considerable amount of good arable land, the tillage of which occupies the greater part of the inhabitants. The principal crops are corn, flax, and rape. Cattle, sheep, and swine are also reared, and the "Sennar" breed of horses is celebrated. The industries of Lippe are almost confined to a little yarn-spinning and linen-weaving. Its trade is also considerable; but, besides agricultural products, timber, meerscham pipes, and starch are exported. The brine springs of Salzdalen produce about 1500 tons of salt annually. In 1880 the population amounted to 120,216 souls, upwards of 95 per cent. of whom were Calvinists (Reformed Church), the remainder being Lutherans, Roman Catholics, and Jews. Education is provided for by two gymnasia and numerous other efficient schools. The principality contains seven small towns, the chief of which are Detmold, the seat of government, and Lemgo. The present constitution was granted in 1836, and is modified by a new election law of 1876. It provides for a representative chamber of twenty-one members, whose functions are mainly consultative. For electoral purposes the population is divided into three classes, rated according to taxation, each of which returns seven members. The estimated revenue in 1881 was £49,200, and the expenditure £50,850. The public debt amounts to nearly £60,000. Lippe has one vote in the German Reichstag, and also one vote in the Federal Council. Its military forces form a battalion of the 6th Westphalian infantry.

II. SCHAUMBURG-LIPPE, or LIPPE-BUCKEBURG, to the north of Lippe-Detmold, consists of the western half of the old county of Schaumburg, and is surrounded by Westphalia, Hanover, and the Prussian part of Schaumburg. The northern extremity of the principality, which is 175 square miles in extent, is occupied by a lake named the Steinhuder Meer. The southern part is mountainous, but the remainder consists of a fertile plain, producing abundant crops of cereals and flax. Besides husbandry, the inhabitants practise yarn spinning and linen-weaving, and the coal-mines of the Buckeburg, on the south-eastern border, are very productive. The great bulk of the population, which in 1880 amounted to 85,374, are Lutherans. The capital is Buckeburg, and Stadthagen is the only other town. Under the constitution of 1868 there is a legislative diet of fifteen members, ten of whom are elected by the towns and rural districts and three by the nobility, clergy, and educated classes, while the remaining two are nominated by the prince. Schaumburg-Lippe sends one deputy to the Federal Council, and has one vote in the Reichstag. It contributes a battalion of riflemen to the imperial army. The budget of 1881-82 showed an estimated revenue of £25,750, which was balanced by the expenditure. The public debt is about £18,000.

History—The district now named Lippe was inhabited in the earliest times of which we have any record by the Cherusci, whose leader Arminius annihilated the legions of Varus in the Teutoburgian Forest (A.D. 9). It was afterwards occupied by the Saxons, and was subdued by Charlemagne. The founder of the present reigning family, one of the most ancient in Germany, was Bernard I. (1129-58), who received a grant of the territory, till then called the county of Haholt, from the emperor Lothar, and assumed the title of lord of Lippe. Bernard VIII., who with his people embraced the tenets of the Reformation in 1556, was the first to style himself count of Lippe. In 1613 Lippe was divided among the three sons of Simon VI., the lines formed by two of whom still exist, while the third (Buke) became extinct in 1709.

Lippe-Detmold was the patrimony of the eldest son, whose descendants became princes of the empire in 1786. In 1809 it joined the Confederation of the Rhine, and in 1813 the German Confederation. Under the present government of the Princess Pauline (1807-20) the little country enjoyed great prosperity. Her son, Paul Alexander Leopold, ruled in the same spirit, and in 1886 granted the charter of rights on which the government is now based. In 1843 Lippe entered the German Customs Union

(Zollverein), and in 1806 it threw in its lot with Prussia and joined the North German Confederation.

Philip, the youngest son of Simon VI (see above), received but a scanty share of his father's possessions, but in 1640 he inherited a large part of the countship of Schaumburg, including Bückeburg, and adopted the title of count of Schaumburg-Lippe. The ruler of this territory became a sovereign prince in 1807. In 1866 the prince at first sided with Austria, but afterwards entered the German Confederation.

For further information consult Falkmann, *Beitrag zur Geschichte des Fürstentums Lippe, 1849*; Schickhaus, *Das Fürstentum Lippe-Deimold in geo-graphischer, statistischer, und geschichtlicher Beziehung, 1856*; *Erinnerungen aus dem Leben der Fürstin Pauline*; in *Sybil's Historische Zeitschrift* (H. 1861).

LIPPI, the name of three celebrated Italian painters.

L. FRA FILIPPO LIPPI (1412-1469), commonly called Lippo Lippi, one of the most celebrated painters of the Italian quattrocento, was born in Florence, — his father, Tommaso, being a butcher. His mother died in his earliest infancy, and his father two years later. His aunt, a poor woman named Monna Lapaccia, then took charge of him; and in 1420, when only eight years of age, he was registered in the community of the Carmelite friars of the Carmine in Florence. Here he remained till 1432, and his early faculty for fine art was probably developed by studying from the works of Masaccio in the neighbouring chapel of the Brancacci. Between 1430 and 1432 he executed some works in the monastery, which were destroyed by a fire in 1771; they are specified by Vasari, and one of them was particularly marked by its resemblance to Masaccio's style. Eventually Fra Filippo quitted his convent, but it appears that he was not relieved from some sort of religious vow; there is a letter of his, dated in 1439, in which he speaks of himself as the poorest friar of Florence, and says he is charged with the maintenance of six marriageable nieces. In 1452 he was appointed chaplain to the convent of S. Giovanni in Florence, and in 1457 rector (*Rettore Commendatario*) of S. Quirico at Legnana, and his gains were considerable, and even uncommonly large from time to time; but his poverty seems to have been chronic none the less, the money being spent, according to one account, in frequently recurring amours.

Vasari relates some curious and romantic adventures of Fra Filippo, which modern biographers are not inclined to believe. Except through Vasari, nothing whatever is known of his visits to Ancona and Naples, and his intermediate capture by Barbary pirates and enslavement in Barbary, whence his skill in portrait-sketching availed to release him. The doubts thrown upon his semi-marital relations with a Florentine lady appear, however, to be somewhat arbitrary; Vasari's account is circumstantial, and in itself not greatly improbable, and to say that he is the sole authority for the facts goes but a small way towards invalidating them. Towards June 1456 Fra Filippo was settled in Prato (near Florence) for the purpose of fulfilling an important commission which had been given him to paint frescoes in the choir of the cathedral. Before actually undertaking this work he set about painting, in 1458, a picture for the convent chapel of St Margaret of Prato, and there saw Lucrezia Buti, the beautiful daughter of a Florentine, Francesco Buti; she was either a novice or a young lady placed under the nuns' guardianship. Lippi asked that she might be permitted to sit to him for the figure of the Madonna; he made passionate love to her, abducted her to his own house, and kept her there spite of the utmost efforts the nuns could make to reclaim her. The fruit of their loves was a boy, who became the painter, not less celebrated than his father, Filippino Lippi (noticed below). Such is substantially Vasari's narrative, published less than a century after the alleged events; it is not refuted by saying, more than three centuries later, that perhaps Lippo had nothing to do with any such Lucrezia, and perhaps Filippino was his adopted son, or only an ordinary relative, and scholar. The argument that two reputed portraits of Lucrezia in

paintings by Lippo, one as a Madonna in a very fine picture in the Pitti gallery, and the other in the same character in a Nativity in the Louvre, are not alike comes to very little; and it is reduced to nothing when the disputant adds that the Louvre painting is probably not done by Lippi at all. This painting comes, however, from St Margaret's at Prato, and is generally considered to be the very one on which Vasari's story hinges.

The frescos in the choir of Prato cathedral, being the stories of the Baptism and of St Stephen, represented on the two opposite wall spaces, are the most important and monumental works which Fra Filippo has left, more especially the last of the series, showing the ceremonial mourning over Stephen's corpse. This contains a portrait of the painter, but which is the proper figure is a question that has raised some diversity of opinion. Some of the subjects are legendary, as, for instance, the attempt of the devil to substitute a changeling for the infant protomartyr. At the end wall of the choir are S. Giovanni Gualberto and S. Albert, and on the ceiling the four evangelists.

The close of Lippi's life was spent at Spoleto, where he had been commissioned to paint, for the apse of the cathedral, some scenes from the life of the Virgin. In the semidome of the apse is Christ crowning the Madonna, with angels, sibyls, and prophets. This series, which is not wholly equal to the one at Prato, was completed by Fra Diamante after Lippi's death.

That Lippi died in Spoleto, on or about 8th October 1469, is an undoubted fact; the mode of his death is again a matter of dispute. It has been said that the pope granted Lippi a dispensation for marrying Lucrezia, but that, before the permission arrived, he had been poisoned by the indignant relatives either of Lucrezia herself, or of some lady who had replaced her in the inconstant painter's affections. This is now generally regarded as a fable; and it may very well be such, although the incident does not present any intrinsic improbability in relation to the Italy of the 15th century. Fra Filippo lies buried in Spoleto, with a monument erected to him by Lorenzo the Magnificent; he had always been zealously patronized by the Medici family, beginning with Cosmo Pater Patriæ. Francesco di Pesello (called Pesellino) and Sandro Botticelli were among his most distinguished pupils.

Some leading pictures by Lippi not already mentioned are the following. In 1461 he painted an altarpiece for the nuns of S. Ambrogio which is now a prominent attraction in the Accademia of Florence, and has been celebrated in Browning's well-known poem. It represents the Coronation of the Virgin among angels and saints, of whom many are Bernardino monks. One of these, placed to the right, is a half-length portrait of Lippi, pointed out by an inscription upon an angel's scroll "In periclit quæ." The price paid for this work in 1467 was 1200 Florentine lire, which seems surprisingly even unaccountably large. For Geminiano Ligurinus of Prato he painted the death of St Bernard, a fine specimen still extant. His principal altarpiece in this city is a Nativity in the refectory of S. Domenico, — the Infant on the ground adored by the Virgin and Joseph, between Sts George and Dominic, in a rocky landscape, with the shepherds playing and six angels in the sky. In the Uffizi is a fine Virgin adoring the infant Christ, who is held by two angels, in the London National Gallery, a Vision of St Bernard. The picture of the Virgin and Infant with an Angel, in this same gallery, also ascribed to Lippi, is disputable.

Few pictures are so thoroughly enjoyable as those of Lippo Lippi: they show the maturity of a strong rich nature, redundant in lively and unrefined whimsical observation. He approaches religious art from its human side, and is not pictorial though true to a phase of Catholic devotion. He was perhaps the greatest colourist and technical adept of his time, with good draughtsmanship, — a naturalist, with less vulgar realism than some of his contemporaries, and with much genuine epical animation, mingling semi-humorous incidents and low characters. His noble little effort after perspective and some of his foreshortenings, was fond of ornamenting pilasters and other architectural features. Vasari says that Lippi was wont to hide the extremities in drapery, to evade difficulties. His career was one of continual development, without fundamental variation in style or in colouring. In his great works the proportions are larger than life.

II. FILIPPINO or LIPPINO LIPPI (1460-1505) was the natural son of Fra Lippo Lippi and Lucrezia Buti, born in Florence and educated at Prato. Losing his father before he had completed his tenth year, the boy took up his avocation as a painter, studying under Sandro Botticelli, and probably under Fra Diamante. The style which he formed was to a great extent original, but it bears clear traces of the manner both of Lippo and of Botticelli,—more ornamental than the first, more realistic and less poetical than the second. His powers developed early; for we find him an accomplished artist by 1480, when he painted an altarpiece, the Vision of St Bernard, now in the Badia of Florence, it is in tempera, with almost the same force as oil painting. Soon afterwards, probably from 1482 to 1490, he began to work upon the frescoes which completed the decoration of the famous Brancacci chapel in the Carmine, commenced by Masolino and Masaccio many years before. He finished Masaccio's subject of the Resurrection of the King's Son, and was the sole author of Paul's Interview with Peter in Prison, the Liberation of Peter, the Two Saints before the Proconsul, and the Crucifixion of Peter. These works, were none others extant from his hand, are sufficient to prove that Lippino stood in the front rank of the artists of his time. The dignified and expressive figure of St Paul in the second-named subject has always been particularly admired, and appears to have furnished a suggestion to Raphael for his Paul at Athens. Portraits of Luigi Pulci, Antonio Pollaiuolo, Lippino himself, and various others are to be found in this series. In 1485 he executed the great altarpiece of the Virgin and Saints, with several other figures, now in the Uffizi Gallery. Another of his leading works is the altarpiece for the Nerli Chapel in S. Spirito—the Virgin Enthroned, with splendidly living portraits of Nerli and his wife, and a thronged distance. In 1489 Lippino was in Rome, painting in the church of the Minerva, having first passed through Spoleto to design the monument for his father in the cathedral of that city. Some of his principal frescoes in the Minerva are still extant, the subjects being in celebration of St Thomas Aquinas. In one picture the saint is miraculously commended by a crucifix; in another, triumphing over heretics. In 1496 Lippino painted the Adoration of the Magi now in the Uffizi, a very striking picture, with numerous figures. This was succeeded by his last important undertaking, the frescoes in the Strozzi Chapel, in the church of S. Maria Novella in Florence—*Drusiana Restored to Life by St John the Evangelist*, St John in the Cauldron of Boiling Oil, and two subjects from the legend of St Philip. These are conspicuous and attractive works, yet somewhat grotesque and exaggerated,—full of ornate architecture, showy colour, and the distinctive peculiarities of the master. Filippino, who had married in 1497, died in 1505 of an attack of throat disease and fever, aged only forty-five. His character for amiability and courtesy is described in very laudatory terms by Vasari. The best-reputed of his scholars was Raffaellino del Garbo.

Like his father, Filippino had a most marked original genius for painting, and he was hardly less a chief among the artists of his time than Fra Lippo had been in his. It may be said that in all the emuls of the art a rival instance is to be found of a father and son each of whom had such pre-eminent natural gifts and leadership. The father displayed more of sentiment, and exquisite sweetness of motive; the son more of richness, variety, and lively pictorial combination. He was admirable in all matters of decorative adjunct and presentment, such as draperies, landscape backgrounds, and accessories; and he was the first Florentine to introduce a taste for accurate details of costume, &c. He formed a large collection of objects of this kind, and left his designs of them to his son. In his later works there is a tendency to a mannered development of the extremities, and generally to faulty overdoing. The London National Gallery possesses a good and characteristic though not exactly a first-rate specimen of Lippino, the Virgin and Child between St Jerome and Dominic.

III. LORENZO LIPPI (1606-1664), a painter and poet, was born in Florence. He studied painting under Matteo Rosselli, the influence of whose style, and more especially of that of Santi di Tito, is to be traced in Lippi's works, which are marked by taste, delicacy, and a strong turn for portrait-like naturalism. His maxim was "to poetize as he spoke, and to paint as he saw." After exercising his art for some time in Florence, and having married at the age of forty the daughter of a rich sculptor named Susini, Lippi went as court painter to Innsbruck, where he has left many excellent portraits. There he wrote his humorous poem named *Malmantile Raccusato*, which was published under the anagrammatic pseudonym of "Parione Zapoli." Lippi was a friend of Salvator Rosa, and was a man of pleasant and generous temper, and very polite. He was, however, somewhat self-sufficient, and, when visiting Parma, would not look at the famous Correggios there, saying that they could teach him nothing. He died of pleurisy in 1664.

The most esteemed works of Lippi as a painter are a Crucifixion in the gallery at Florence, and a Triumph of David which he executed for the saloon of Angiolo Galli, introducing into it portraits of the seventeen children of the owner. His poem the *Malmantile Raccusato* is a burlesque romance, mostly compounded out of a variety of popular tales; its principal subject-matter is an expedition for the recovery of a fortress and territory whose queen had been expelled by a female usurper. It is full of graceful or racy Florentine idioms, and is counted by Italians as a "testo di lingua." Lippi is more generally or more advantageously remembered by this poem than by anything which he has left in the art of painting. It was not published until 1688, several years after his death. (W. M. R.)

LIPSIUS, JUSTUS (1547-1606), the Latinized form of Joest Lips, an eminent humanist of the 16th century, born 18th October 1547, at Overysche, a small village in Brabant, about half way between Brussels and Ottignies. Sent early to the Jesuit college in Cologne, he was removed at seventeen to the university of Louvain by his parents, who had some reason for fearing that he might be induced to become a professed member of the Society of Jesus. But he had received at Cologne two mental tendencies from which he never emancipated himself. One of these, which was suppressed or suspended in middle life, asserted itself later in his return to the bosom of the Catholic Church before his death. The other, derived from his Jesuit training, showed itself in his merely rhetorical or verbal view of classical literature, of which the one interest lay in its style.

Lipsius rushed into print at twenty with one of those volumes of miscellaneous remarks then in vogue (*Variorum Lectionum Libri Tres*, 1567), the dedication of which to Cardinal Granvelle procured him an appointment as Latin secretary, and a visit to Rome in the retinue of the cardinal. Here Lipsius remained two years, using his spare time in study of the Latin classics, in viewing the monuments, collecting inscriptions, and handling MSS. in the Vatican. A comparison of a second volume of miscellaneous criticism (*Antiquarum Lectionum Libri Quinque*, 1575), published after his return from Rome, with the *Varie Lectiones* of eight years earlier shows that he had advanced from the notion of purely conjectural emendation to that of emending by collation, and that he had learnt to distinguish between a "good" and a "bad" MS. In Rome he also made the acquaintance of Muretus, Paulus Manutius, and the other humanists of the catholic reaction who were then in credit there. He was also noticed by Cardinal Sirlosto and Fulvio Orsini; but he can hardly have even seen in the street Scrinio and Vettori, and the introduction of these celebrated names is perhaps only a stylistic flourish of the biographer Lo Miro, to whom we owe the only original account of Lipsius's life. In 1570 he wandered over Burgundy, Germany, Austria, Bohemia, in search of learn-

ing and learned acquaintance, and was engaged for more than a year as teacher in the university of Jena, a position which implied an outward conformity to the Lutheran Church. On his way back to Louvain, he stopped some time at Cologne, where he must again have comforted himself as a Catholic. Here he married, but the union was without issue, and in other respects did not conduce to happiness, as we gather from various allusions scattered through Lipsius's letters. He returned to Louvain, but was soon driven by the civil war to take refuge in Antwerp, where he received, in 1579, a call to the newly founded university of Leyden, as professor of history.

At Leyden, where he must have outwardly conformed to the Calvinistic creed and worship, Lipsius remained eleven years,—years about which his Catholic biographer Le Mire has nothing to tell, but speaks of the period as an enforced temporary sojourn among the infidels,—till the restoration of peace allowed him to return to his home in Brabant. In truth, this period of Lipsius's life was the period of his greatest productivity. It was now that he prepared his *Seneca*, and that he perfected, in successive editions, his *Tacitus*. To edit and comment on two authors of the first class, such as Tacitus and Seneca, in addition to the daily drudgery of teaching, might seem work enough for eleven years. But Lipsius's industry enabled him, over and above, to bring out, from the press of Plantin at Antwerp, a series of works of varied character and contents, some of pure scholarship, others collections from classical authors, and others again of more general interest. Of this latter class was a treatise on politics (*Politiorum Libri Sex*, 1589), in which he let it be seen that, though a public teacher in a country which professed toleration, he had not departed from the state maxims of Alva and Philip II. He lays it down that a Government should only suffer one religion to exist in its territory, and that dissent should be extirpated by fire and sword. This frank avowal of what were known to be his real sentiments might have easily had disagreeable consequences for the author, if he had not been sheltered from the attacks to which it exposed him by the prudence of the authorities of Leyden. Lipsius was prevailed upon to publish a declaration that his expression "*Ure, secca*," was not intended of material fire and sword, but was only a metaphor for "vigorous treatment."

The time at last arrived when Lipsius, who had always been somewhat ill at ease in his Calvinistic disguise, was to throw it off and return into the bosom of the church. In the spring of 1591 he left Leyden under pretext of taking the waters at Spa for the relief of a liver complaint. He went to Mainz, where he was reconciled to the church by the instrumentality of the Jesuit fathers. The event was one which deeply interested the Catholic world, and invitations poured in on Lipsius from the courts and universities of Italy, Austria, and Spain. But he preferred to remain in his own country, and after two years of unsettled residence at Liège, Spa, &c., settled at Louvain, as professor of Latin in the Collegium Bushidianum. He was not expected to teach, and his trifling stipend was eked out by the appointments of privy councillor and historiographer to the king of Spain.

From this time till his death Lipsius continued to publish antiquarian collections and dissertations as before. But he was, in fact, lost to learning. His name and fame, and his sententious and amusing style, were placed at the disposal of the Jesuits, and used by them to restore the credit of two local images of the Virgin, whose authentic miracles were retailed by Lipsius in two tracts, *Divia Virgo Hallensis*, and *Divia Virgo Sichemensis*. Joseph Hall, afterwards bishop of Norwich, was at Spa in the suite of Sir E. Bacon at the time of the appearance of Lipsius's brochures, and was like to have got into trouble by disput-

ing against them (Hall's *Epistles*, cent. i. ep. 5). Lipsius died at Louvain on the 23d of March 1606, at the age of fifty-eight. His Greek books and MSS. he left to the Jesuit college at Louvain, the rest of his library, choice rather than extensive, to a nephew. His furrowed doctor's robe he ordered to be offered at the shrine of the Virgin at Hall.

As, according to the fancy of some biographers, Scaliger, Casaubon, and Lipsius he erected into a literary thronum, Lipsius represents *Lapida*. His knowledge of classical antiquity was extremely limited. He had but slight acquaintance with Greek, "pour sa provision" only, said Scaliger. He is fond of adorning his letters with Greek phrases, his quotations betraying that he is a stranger to that country. In Latin literature the poets and Cæsar lay outside his range; he had no ear for metre, and no taste for poetical expression. Where he was strong was in the Latin historians and in Roman antiquities. His greatest work was his edition of Tacitus. This author he had so completely made his own that he could repeat the whole, and offered to be tested in any part of the text with a poniard held to his breast, to be used against him if he should fail. His *Tacitus* first appeared in 1575, and was five times revised and corrected by the editor—the last time in 1606, shortly before his death. His *Seneca* is dated Antwerp, 1595. His *Opera Omnia* were collected in 4 vols., Antwerp, 1637, of which the West edition, 1676, is a verbal reprint in the same number of volumes, but in a smaller form. The first volume contains also Le Mire's *Life of Lipsius*, which had appeared separately in 1607. Both editions contain ten centuries of his epistles, to which additions have been made in *Epistolæ novæ* or *ant. Decretis XII.*, &c. Hædericij, 1621; *Burmann's Collige*, tom. 1., *Lettres inédites*, ed. Dolyat, Amst., 1858. On Lipsius's relations with Scaliger see Berner's *J. J. Scaliger*, note 40. A bibliographical list of his separate publications, forty-eight in number, may be found in Nicéron, *Mémoires*, xxiv. p. 118. (M. F.)

LIQUEURS are perfumed and sweetened spirits prepared for drinking, and for use as a flavouring material in confectionery and cookery. The term liqueur is also applied to certain wines and spirits remarkable for their amount of bouquet, such as tokay and liqueur brandy, &c. Ordinary liqueurs consist of certain mixtures of pure spirit with essential oils and vegetable extracts, and with syrup of refined sugar. A certain number of such preparations have an established reputation; but the methods by which these are compounded, and the precise proportions of the various ingredients they contain, are valuable trade secrets, scrupulously kept from public knowledge.

The raw materials employed in the preparation of liqueurs are—(1) a pure flavourless spirit, which must be free from fuel oil; (2) various essential oils, on the purity and constant quality of which much of the success of the manufacture depends, or, in place of the oils, the aromatic substances from which they may be distilled; (3) bitter aromatic vegetable substances, fruits, rinds, &c., or their alcoholic extracts called tinctures; (4) fresh juicy fruits possessed of special flavour; (5) refined sugar prepared in the form of a perfectly smooth colourless syrup; (6) soft or distilled water; and (7) tinctorial substances for those liqueurs in which a particular colour is demanded by fashion. The French, who excel in the preparation of liqueurs, grade their products according to their sweetness and alcoholic strength into *crèmes*, *huiles*, or *baumes*, which have a thick oily consistency, and *cassis*, *extraits*, or *elixirs*, which, being less sweetened, are perfectly limpid. Liqueurs of British fabrication, generally of inferior quality, are frequently dealt in under the name of *cordials*. Bitters form a class of liqueurs by themselves, claiming to possess certain tonic properties and a medicinal value. Certain liqueurs, containing only a single flavouring ingredient, or having a prevailing flavour of a particular substance, are named after that body, as for example—*crème de rose*, vanilla, *thé*, *escau*, *anisette*, and *kummel*, &c. On the other hand, the liqueurs which in general are most highly prized are compounded of very numerous aromatic principles, and they are not considered fit for use till they have matured and mellowed for several years.

The simplest method of preparing liqueurs is by adding the requisite proportion of essential oil to spirit of known strength, and then mixing this with the necessary amount of clear syrup. In this way, indeed, the greater number of the commoner and cheaper kinds are manufactured. Thus for making (say) 20 gallons inferior quality of kummel, there are added to 7 gallons of spirit of wine $\frac{1}{2}$ lb of essential oil of caraway seed, $7\frac{1}{2}$ drachms of fennel-seed oil, and 15 drops of bitter almond oil. With this preparation is mixed a syrup containing 40 lb of refined sugar dissolved in about 12 gallons of water, and when fined with gelatine or with alum and soda solution the liqueur is ready for use.

To prepare, on the other hand, 20 gallons of fine kummel liqueur, there would be placed in a simple still, with 10 gallons of spirit and 8 of water, 4 lb of caraway seeds, $\frac{1}{2}$ lb of fennel, and 3 oz of Florentine iris root. This mixture after maceration is distilled, the first portion of the distillate being put aside on account of its rough aroma, after which about 8 gallons of fine kummel spirit is obtainable. There still may be procured, by forcing the heat, from 3 to 4 gallons of inferior spirit. To the 8 gallons of fine spirit is added a syrup consisting of 50 lb of refined sugar dissolved in 10 gallons of water, the two compounds being thoroughly incorporated with heat in an open vessel. On cooling, the amount of water necessary to make up 20 gallons is added; the liqueur is fined with isinglass, and stored to mature and mellow. All varieties of liqueurs may be made or imitated by both these methods; but as a rule it is only the simple-flavoured and commoner varieties which are compounded by the addition of essential oils and alcoholic tinctures. Fine liqueurs are made by macerating aromatic bodies and subsequent distillation; bitters by maceration and straining.

Of trade liqueurs the most highly esteemed in the United Kingdom are Chartreuse, Curaçao, Maraschino, and Doppel-Kummel or Almond. Of all kinds the most famous is *Chartreuse*, as could have been made at the famous Carthusian monastery near Grenoble. Three qualities are made—green, yellow, and white, the green being the richest and most delicate in flavour. Chartreuse is said to be a most complex product, resulting from the maceration and distillation of balm leaves and tops as a principal ingredient, with orange peel, dried hyssop tops, peppermint, wormwood, angelica seed and root, cinnamon, mace, cloves, Tonguin beans, *Culemus aromaticus*, and cardamoms. *Curaçao*, which is a simple liqueur, is chiefly made in Amsterdam from the dried peel of the Curaçao orange. The peel is first softened by maceration in water, then three-fourths of the quantity in preparation is distilled with mixed spirit and water, and the remaining fourth is macerated in a proportion of this distillate for two or three days, the tincture is strained off and expressed and added to the original distilled Curaçao spirit. The flavour of Curaçao is improved by the addition of about one per cent. of Jamaica rum. The centre of the *Maraschino* trade is at Dalmatia. Genuine Maraschino is prepared from a variety of cherry—the Marasca—peculiar to the Dalmatian mountain regions. The juice of the cherry fermented and distilled yields the spirit, which is flavoured with the broken cherry kernels themselves. Imitations of Maraschino are easily prepared, a paliseworthy liqueur resulting from raspberry juice, bitter almonds, and orange-flower water. In the preparation of *Almond*—which is a rich Kummel—bitter almonds, star-anise, angelica root, Florentine iris root, and orange peel are used in addition to caraway seeds. Gold-water and silver-water are liqueurs to which small quantities of powdered gold-leaf and silver-leaf have been added, on account of their lustre. They are now little used.

Gentian root is the fundamental "bitter" in most of the preparations known as *Bitters*. These compounds, prepared by maceration, are very various in their constitution, but the following is a fair typical example of the composition of a kind largely used. To prepare 20 gallons of bitters there are taken 3 lb of gentian, 6 lb each of cinnamon and caraway seeds, 1 lb of juniper berries, and $\frac{1}{2}$ lb of cloves. These are macerated in 7 gallons of spirit, 60° over proof, strained and filtered, and to the product is added 10 lb of sugar dissolved in 18 gallons of water, and the resulting liquor is coloured with cochineal.

The following list includes the names of the principal commercial liqueurs not already named:—Noyau (white and pink), trappistine (yellow and green) (from the Abbey de la Grande Chartreuse), benedictine (from Rézeaux), peppermint liqueur, French cherry brandy or Kirsbaer (from Copenhagen), maritane, peridot amon, crème de

vanille, crème de rose, thé, café, menthe, cacao, vanille, pomegranate, anis (from Dantz), anisette (from Amsterdam and Bordeaux), kirschenwasser (from Switzerland and the Black Forest), absinthe, and vermouth. (J. P.)

LIQUIDAMBAR, LIQUID AMBER, or SWEET GUM, is a product of *Liquidambar styraciflua*, L., order *Hamamelidaceae*, a deciduous tree of from 30 to 50 feet high and attaining 15 feet in circumference in Mexico, of which country it is a native, as well as of the greater portion of the United States. It bears palmately-lobed leaves, somewhat resembling those of the maple, but larger. The male and female inflorescences are on different branches of the same tree, the globular heads of fruit resembling those of the plane. This species is nearly allied to *L. orientalis*, Miller, a native of a very restricted portion of the south-west coast of Asia Minor, where it forms forests. It is from the bark of this latter tree that the storax of the ancients (Herod., ii. 107, Diosc., i. 79), the medicinal storax of to-day, is prepared (Bentley and Trimen, *Med. Plants*, No. 107). The earliest record of the tree appears to be in a Spanish work by F. Hernandez, published in 1651, in which he describes it as a large tree producing a fragrant gum resembling liquid amber, whence the name (*Nov. Plant.*, &c., p. 56). In Ray's *Historia Plantarum* (1686) it is called *Styrax liquidá*. It was introduced into Europe in 1681 by Banister, the missionary collector sent out by Bishop Compton, who planted it in the palace gardens at Fulham.

The wood is very compact and fine-grained,—the heart-wood being reddish, and, when cut into planks, marked transversely with blackish belts. It is employed for veneering in New York. Being readily dyed black, it is sometimes used instead of ebony for picture frames, balusters, &c.; but it is too liable to decay for outdoor work. The principal product of the tree, however, is the resinous gum which issues from between the bark and wood. It is sometimes called white balsam of Peru, or liquid storax, though it is said by Michaux (*Les Plantes rétrosives*, ii. p. 337) to differ materially from the latter. It is considered to be styptic and to possess healing and balsamic properties, being stimulant and aromatic. It possesses nearly the same properties as the balsam of Peru and of Tolu, for which it is often substituted, as well as for storax. Mixed with tobacco, the gum was used for smoking at the court of the Mexican emperors (Rumph., iv. 10). It has been long used in France as a perfume for gloves, &c. It is mainly produced in Mexico, little being obtained from trees growing in higher latitudes of North America, or in England. For localities where it has been observed, see Pickering's *Chron. Hist. of Plants*, p. 741.

LIQUORICE. The hard and semi-vitreous sticks of paste, black in colour and possessed of a sweet somewhat astringent taste, known as liquorice paste or black sugar, are the inspissated juice of the roots of a leguminous plant, *Glycyrrhiza glabra*, the *radix glycyrrhizae* of the pharmacopoeia. The plant is cultivated throughout the warmer parts of Europe, especially on the Mediterranean shores, and its geographical limits travel eastward throughout Central Asia to China, where its cultivation is also presented. In the United Kingdom it is grown in Surrey and in Yorkshire. The roots for use are obtained in lengths of 3 or 4 feet, and varying in diameter from $\frac{1}{4}$ to 1 inch, soft, flexible, and fibrous, and internally of a bright yellow colour with a characteristic sweet pleasant taste. To this sweet taste of the root the plant owes its generic name *Glycyrrhiza* (the sweet root), of which liquorice is a corruption. According to the analysis of Sestini (*Gaz. Chim. Ital.*, vol. viii. p. 181), the root dried at 110° C. has the following composition:—resin, 5.64, and colouring matters, 8.220; glycyrrhizin, 6.878; starch, 67.720; cellulose, 19.790; albuminoid substances,

6-373; ammonia (combined), 0-043; asparagine, 2-416, ash, 4 000 It is to the sugar-like body glycyrrhizin in combination with ammonia that the peculiar taste and properties of liquorice root are due. Glycyrrhizin in itself is a tasteless nearly insoluble substance having the composition of $C_{42}H_{64}O_{16}$, but in combination with ammonia, potash, or soda it develops its sweet taste. It is easily precipitated from its combination by the influence of mineral acids. Liquorice has been known and its virtues appreciated from the most remote periods, and the root is an article of some commercial importance on the Continent.

Stuck liquorice is made by crushing and grinding the roots to a pulp, which is boiled in water over an open fire, and the decoction separated from the solid residue of the root is evaporated in copper pans till a sufficient degree of concentration is attained, after which, on cooling, it is rolled into the form of sticks or other shapes for the market. The preparation of the juice is a widely extended industry along the Mediterranean coasts; but the quality best appreciated in the United Kingdom is made in Calabria, and sold under the names of Solena and Congiano juices. The liquorice grown in Yorkshire is made into a confection called Pottfract cakes. Liquorice in various forms is a popular remedy for coughs, and it is largely used by children as a sweetmeat. It enters into the composition of many cough lozenges and other demulcent preparations, and in the form of aromatic syrups and elixirs it has a remarkable effect in masking the taste of nauseous medicines, a property peculiar to glycyrrhizin. A considerable quantity of liquorice is used in the preparation of tobacco for chewing. Commercial liquorice paste is frequently much adulterated, and often contains distinct traces of copper, apparently derived from the vessels in which the juice is inspissated.

LIQUOR LAWS may be divided into the three great systems of free trade, restriction, and prohibition. The system of free trade may mean either that no special licence is required by law for carrying on a traffic in intoxicating liquors, or that such a licence is required, but that the licensing authority is bound to grant it in every case in which certain conditions are complied with. Wherever the determination of these conditions involves an appeal to the discretion of the licensing authority, the system of free trade tends to pass into the system of restriction. For practical purposes it does not matter much whether the law says, "every man of good character is entitled to a licence for a properly constructed house in a suitable locality," or "the magistrate must consider the character of the applicant and of the premises, but is not bound to give reasons for his decision." But wherever the applicant can submit to a court capable of dealing with evidence the question of fact whether he has fulfilled certain conditions defined by law, the system of free trade may be said in theory to exist. Wherever, on the other hand, the law distinctly affirms an absolute discretion in the magistrate, or lays down a positive principle, such as the "normal number" or the fixed proportion between public-houses and population, the system is properly described as restriction, or monopoly. This system, again, in its extreme form, tends to pass into one of prohibition. Under one of the alternative plans permitted by the Swedish licensing law of 1865, generally known as the Gothenburg plan, the municipality begins by the partial, and advances to the total, prohibition of liquor traffic, except by servants of the municipality; and this plan is sometimes advocated merely as a step towards the suppression of all trade in liquor. In nearly all countries the nature of the trade carried on in public-houses has subjected them to a much more rigorous police supervision than ordinary trades. All trades, however, must be carried on under the conditions required by the public comfort and safety; and to give unlimited licence in such matters to publicans would be to violate social rights not inferior to freedom of industry and trade.

Of recent years there has been a considerable increase in the amount of drunkenness in Europe generally. There

are no means of determining the law of the increase by reliable statistics, but it seems probable that the increase is confined to the large towns and to the lowest classes. There has also been of late, both in the United Kingdom and on the Continent, a very earnest and animated discussion on the policy and results of the various systems of liquor law. It cannot be said that so far any decisive experience has been adduced on the subject. In fact the legislation of Europe is in a very uneasy and changeable state. Thus, prior to the federal constitution of 1874, the cantons of Switzerland were in the habit of directing the municipal authorities to observe a certain proportion between the number of licences and the population. The new constitution, however, laid down the general principle of free trade, and the federal council intimated to the various cantons that it was no longer lawful to refuse a licence on the ground that there was no public need of it. In the previous year precisely the opposite change took place in Denmark. The licence system rested on the law of 29th December 1857, but this was modified by the law of 33d May 1873, which increased the conditions to be fulfilled by those applying for a licence, and conferred upon the communal authorities the power of fixing the maximum number of licences to be granted. Similarly, in France, the liquor law rests upon the decree of 1851, but public opinion is turning against the absolute discretion reposed in the administrative authority, and the law proposed by M. de Gasté and approved of by the chamber of deputies on 22d March 1878 will probably lead to a system of greater freedom. In the German empire the various states are still permitted by a law of the confederation, dated 21st June 1869, to restrict the issue of licences to what the public seem to require, but except in Württemberg this permission seems not to have been used. In Austria the rapid growth of drunkenness in Galicia made necessary the severe police law of 19th July 1877, but in other parts of the empire the exceptionally lenient law of 20th December 1859 seems to be considered sufficient. In the midst of so many fluctuations of opinion, the practical questions of legislation must be decided on general principles and not by experimental evidence. Those who speak and write on the reform of the liquor laws are divided into two great classes—(1) the nephalists, who consider alcohol, in every form, whether in distilled or in fermented liquors, to be poison, and therefore wish the sale of it to be entirely suppressed; (2) those who see no objection to moderate drinking, especially of the less alcoholic beverages, or at least regard the idea of suppression as an impracticable chimæra. In the United Kingdom the nephalists are at present agitating for Sir Wilfrid Lawson's Permissive Bill, which has latterly taken the form of a local option resolution. This means that in each burgh or parish two-thirds of the ratepayers may decide that no licences shall be given, a vote to be taken on the subject every three years. On 17th March 1879 the select committee of the House of Lords on intemperance reported emphatically against the scheme of the Permissive Bill. The committee did not examine witnesses from the United States with respect to the experiments in prohibition which have been made there on a large scale; but it is generally admitted that the Maine Liquor Law has succeeded only in villages and rural districts; in towns it has failed. So also the Michigan Law, prohibiting the sale of liquor except for medicinal or mechanical purposes, was condemned after twenty years' experience; and in 1876 a licence tax was imposed on dealers in liquor.

The result is the same under those celebrated "local option laws" which are in force in some of the United States. These laws proceed from the legislatures of the various States. They sometimes take the form of a general prohibition of the sale of intoxicants,

subject to a vote of the inhabitants in each township or county, but more frequently they merely provide in general terms for the issue of licences in the usual way, unless the local constituency shall otherwise determine. Such laws are in force in Massachusetts, New Jersey (which had the *Chatham Local Option Law of 1871*), New Hampshire, Connecticut, and Vermont. But whether they are constitutional or not is a matter of serious controversy in the courts of the United States. On the one hand, it is said that such a law amounts to a delegation by the State of its legislative power,—that it leaves the hands of the senate and general assembly in an unfinished state, commanding nothing, prohibiting nothing. On the other hand, it is said this is a police regulation, which is properly entrusted to county commissioners, or boards of select men for the protection of the health and morals of the localities over which they preside; and it is quite competent for a State to make a law delegating the power to determine some fact or state of things, upon which the law makes, or intends to make, its own action depend. In the case of the States already mentioned the constitutional character of the local option law has been upheld by decision, but in the cases of Delaware, Texas, Indiana, California (Wall's Case), Iowa, and Pennsylvania, it has been denied. The question has also been raised in the American courts whether in the case of intoxicants being imported from one State to another a local option law, which prohibits the sale of the imported goods, does not violate the freedom of commerce which is guaranteed to all the States by the American Constitution.¹

Among those who are not nephelists a variety of schemes has been suggested. A small minority are in favour of free trade subject to certain conditions. An experiment of this kind was tried by the Liverpool magistrates in 1853. "The premises were to be of high rateable value, the excise duty was to be greatly increased; the licensee was invariably to reside on the premises, and a special police for the inspection of licensing houses was to be provided." These conditions being complied with, no licence was refused. This experiment was made the subject of inquiry by Mr Villier's select committee of 1854. That committee, which included Sir George Grey and Lord Sherbrooke (Mr Lowe), reported unanimously in its favour. A similar experiment² was made in Liverpool during the years 1852-56 without evil results, and also since 1862 in the Prescott division of the county of Lancashire. On the Continent the only countries where free trade prevails are Belgium, Holland, Greece, Spain, and Roumania. In certain parts of Bavaria communes possess breweries, the produce of which they are by custom entitled to sell without any licence; and the Rhenish Palatinate has never been subject to the restrictions mentioned below which apply to the rest of the empire. In Belgium licences are unknown. The only tax which the publican pays is the "patent" which is paid by every trade. So strong is the general law in Belgium that in 1866, when the municipal authorities of Antwerp issued a regulation prohibiting the sale of alcoholic drinks in the streets, this was held to be illegal by the court of cassation. The Dutch law is the same as in Belgium. It must not be supposed, however, that the Dutch are satisfied with the present law. The Dutch "society for total abstinence from strong drink" is very active; and in 1880 the Government presented to the lower chamber a bill, introducing a licence and also the principle of the normal number, the proportion of licences to population varying according to the total population of towns. In Belgium the *Association contre l'abus des boissons alcooliques* is endeavouring to secure amendments of the law, chiefly of a fiscal and police character, but the introduction of the licence is not suggested. In Germany, with the ex-

¹ See Cooley, *On Constitutional Limitations*, and *On Taxation*, p. 408; Dillon, *On Municipal Corporations*, l. p. 393, and the recent case of *Boyd v. Bryant*, 37 Amer. Rep. 6. In some States it has been attempted to prohibit indirectly by raising enormously the licence fee. The subject is frequently before the courts, and it is decided that while the licensing power is given for revenue purposes there is no limit to the discretion of the licensing authority, but where it is given for purposes of regulation the fee should not exceed the expense of issuing the licence and inspecting and regulating the licensed trade.

ception of Wurtemberg and those places where the licence is unknown, the liquor trade is practically free. The law of 1869 declares that a licence can be refused for two reasons only—if the police condemn the structure or situation of the premises, or if the applicant is likely to encourage drunkenness, gaming, resort of theft, or improper meetings. This system may be contrasted with those of Italy and Russia. In Italy, under the law of 20th March 1865, a licence is obtained from the sub-prefect or *autorità pubblica del circondario* on the demand of the *syndico (municipio)* of the commune and after consulting with the municipal *giunta*. In Russia, under the decree of 1861 and the communal law of 28th June 1870, the licence is got from the municipal or communal council, or, in certain cases, from the owners of land, especially church land. In both countries the licensing authorities have unlimited discretion, which they have exercised so as to multiply public-houses enormously. Assuming that sufficient guarantees can be got for the respectability of the applicant and the good sanitary condition of his premises, the system of free trade, or of unrestricted licensing on defined conditions, is the only one which can be defended on principle. It is impossible for the magistrates to exercise a just discretion in deciding what public-houses are required for a locality. The fact that an applicant has invested capital in the business and is ready to begin is the best evidence that there is a demand to be supplied. There is, however, no prospect of free trade being established in the United Kingdom. The select committee of 1879 reported against it.

A larger number of licensing reformers support the scheme for introducing the "normal number" to the United Kingdom. This was embodied in the bills of Sir Robert Anstruther and Sir Harcourt Johnstone (1876). No new licences were to be granted till the number had been reduced to 1 in 500 of the population in towns, and 1 in 300 in country districts. At present the proportion is 1 to 173 of the population in towns in England and Wales. It seems impossible to determine any such proportion *ad hoc*. Even were it possible, the rough classification of towns by population, and the failure to discriminate between various rural districts, would result in great injustice. In Mr Cowen's bill of 1877 and Lord Colin Campbell's bill of 1882 it was proposed to have in each locality a separate licensing board elected annually by the ratepayers. This proposal runs against the recognized principle in the reform of local government that authorities must be consolidated, not multiplied. The select committee of 1879 suggested that the function of licensing might be entrusted to the proposed representative county boards.

Another scheme, which has the advantage of appealing to modern experience in Europe, was contained in Sir Robert Anstruther's bills of 1872 and 1874 and Mr Chamberlain's bill of 1877. These were all modifications of the Gothenburg system, which Mr Carnegie, a Scotch brewer in Gothenburg, has done much to make known in the United Kingdom. In Sweden, prior to 1855, there was absolute free trade in liquor. The General Licensing Act, passed in that year, gave power to local authorities, subject to confirmation by the provincial governor, to set annually the number of licences, and to sell them for three years on certain conditions. If a company, or "bolag," were formed for the purpose of taking all the licences, the local authority might contract with the company for three years. The Act did not apply to beer. The result of this Act has been twofold. In rural districts almost no licences have been issued. In towns, on the other hand, drinking has increased of late, and has led to the severe police laws of 18th September 1874 and 15th October 1875. In 1866 Gothenburg set the example of transferring the whole public-house traffic to a bolag, which undertakes to appropriate no profit

from the business, but to conduct its establishments in the interest of temperance and morality, and to pay over to the municipality the profits made beyond a fair interest on capital. This experiment has been a great financial success, and if developed will relieve the town from the greater part of its local taxation. The example has been followed by every town in Sweden having a population above 5000; and in 1877, after long discussion, it was adopted in Stockholm, the capital, where the number of life licences presented unusual difficulties. Mr Chamberlain proposed that the work done by the Swedish hogs should be attempted by town councils in the United Kingdom. For this purpose he asked power to acquire the freehold of all licensed premises and the interests of the licence holders. The business would then be carried on by the town council, the profits being carried to the credit of the education and poor rates. The powers of the licensing justices would cease on the adoption of the scheme by the town council. The select committee of 1879 recommended that legislative facilities should be given for the adoption of this scheme. It is doubtful, however, if the burden would be generally submitted to, except on the understanding that the local rates would be *pro tanto* diminished; and, were this realized, the tendency would be to support the municipality on the liquor trade by extending its operations.

The great mass of opinion in the United Kingdom, however, seeks some modification of the present licensing system. That system is extremely complicated. The wholesale licences are granted by the excise without a magistrate's certificate, but for nearly all retail licences such a certificate is required. Generally, the magistrate has absolute discretion as regards licences to sell on the premises, but in England a licence to sell off the premises can be refused only for one or more of the following reasons—no satisfactory evidence of good character, disorderly house, previous forfeiture of licence by misconduct, want of legal qualification. The English law is contained in the Wine and Beerhouses Act 1859, and the Licences Act 1872 and 1874. The great features of the legislation of 1872 were (1) the introduction of a confirming authority (*viz.*, the licensing committee in counties and the whole magistrates in boroughs) for the purpose of restricting the issue of new licences, (2) the qualification of annual value of public-house premises for the purpose of raising the character of those engaged in the trade; (3) the new regulations for closing; (4) the new regulations of police penalties, especially with reference to the endorsement of convictions on the licence and the forfeiture of the licence. The Act of 1874 abolished the necessity of confirmation in the case of "off" licences, gave the magistrates absolute discretion as regards the endorsement of convictions, and removed from magistrates all discretion as regards closing hours. There are not many peculiarities in the licensing law of Ireland. Public-house licences are generally held by shopkeepers, and no qualification of value is required except in the case of beerhouses. Mr Melson's Act of 1877 (37 & 38 Vict. c. 69) closed public-houses on Sunday. In Scotland prior to 1858 licences were regulated by the Home-Drummond Act (9 Geo. IV. c. 58), which authorized only one form of certificate for "common inns." In 1846 a select committee reported that the combination of the grocer trade with the sale of spirits to be consumed on the premises was conducive of evil to the working classes. This led to the Forbes Mackenzie Act of 1855, which was amended in 1862, upon the report of a royal commission in 1860 (13 & 17 Vict. c. 67; 25 & 26 Vict. c. 25). It created three licences—(1) for hotels, (2) for public-houses, (3) grocers' licences. Under the hotel licence interesting liquor may be sold to lodgers and travellers. On Sundays the public-houses are closed, and on week days the sale is practically limited to the period between 8 A.M. and 11 P.M. Cameron's Act of 1876 (39 & 40 Vict. c. 26) makes the refusal of a certificate by the magistrate final, and in the case of a new licence requires the confirmation of a county licensing committee or in boroughs of a joint committee of magistrates and justices.

Information on this subject is to be found chiefly in the *Reports* of royal commissions and select committees. It has been much discussed at the meetings of the Social Science Association, and there is a large literature of pamphlets and magazine articles, to which, among many others, Lord Sherbrooke, Mr Chamberlain, and Mr Arthur Arnold have contributed. The reports of the various international congresses "pour l'étude des questions relatives à l'alcoolisme" may be studied with advantage. See also *Alkohol und seine Folgen*, *Europäische Arbeiten zur Bekämpfung des berauschenden Alkohols*, Paris, 1879 (W. O. S.).

¹ 32 & 38 Vict. c. 27; 35 & 38 Vict. c. 94; 37 & 38 Vict. c. 49.

² So also the first English Act, 5 & 6 Edw. VI., provided one form of licence for "Alehouses."

LISBON (Portuguese, *Lisboe*), the capital of the kingdom of Portugal, is situated in 38° 42' N. lat. and 9° 8' W. long., on the northern bank of the Tagus (*Tago*), at the spot where the river broadens to a width of 9 miles, some 8 or 9 miles from the point where it enters the Atlantic. Standing on a range of low hills, backed by the lofty granite range of Cintra, and extending along the margin of the wide Tagus, Lisbon wears a very noble aspect to those who approach it from the sea. In regard to beauty of position it may rightly claim to be the third of European cities, Constantinople and Naples alone ranking before it. The river affords secure anchorage for a very large number of vessels, and the bar at the mouth is easily crossed even in rough weather. Like London, Paris, and Vienna, Lisbon stands in a geological basin of Tertiary formation. The upper portion consists of loose sand and gravel destitute of organic remains, below which is a series of beds termed by Mr Daniel Sharpe the Almada beds, composed of yellow sand, calcareous sandstone, and blue clay, rich in marine remains. The greater part of Lisbon stands on those beds which belong to the older Miocene epoch, and are nearly of the same age as those of Bordeaux. Next comes a conglomerate without fossils. These Tertiary deposits, which cover altogether an area of more than 2000 square miles, are separated, near Lisbon, from rocks of the secondary epoch by a great sheet of basalt which covered the Secondary rocks before any of the Tertiary strata were in existence. The uppermost of the Secondary deposits is the Hippurite Limestone, which corresponds to a part of the Upper Chalk of northern Europe. The narrow valley of Alcantara, in the immediate neighbourhood of Lisbon, has been excavated in this deposit, and here there are extensive quarries, where abundance of its peculiar shells may be collected.¹

Lisbon stretches along the margin of the river for 4 or 5 miles, and extends northward over the hills for nearly 3 miles, but much of it is scattered amongst gardens and fields. In the older parts the streets are very irregular, but that portion which was rebuilt after the great earthquake of 1755 consists of lofty houses arranged in long straight streets. Here are the four principal squares, the handsomest of which, the Praça do Commercio, is open on one side to the river, and on the other three is surrounded by the custom-house and Government offices, with a spacious arcade beneath. In the middle is a bronze equestrian statue of Joseph I., in whose reign the earthquake and restoration of the city took place. At the middle of the north side is a grand triumphal arch, under which is a street leading to another handsome square, the Rocio or Praça do Dom Pedro (built on the site of the Inquisition palace and prisons), where stands the theatre of D. Maria II. The houses are for the most part well built, and are divided into flats for the accommodation of several families. The streets had formerly a bad reputation in regard to cleanliness, but of late years great improvement has taken place in this respect, although no general system of drainage has yet been adopted. They are lighted with gas made from British coal. The public gardens, five in number, are small, but are much frequented in the evenings. The city contains seven theatres and a bull ring. The hotels of Lisbon offer but indifferent accommodation to

¹ After careful investigation, Mr Sharpe discovered that the greatest force of the earthquake of 1755 was expended upon the area of the above-mentioned Almada blue clay, and that not one of the buildings standing upon it escaped destruction. Those upon the slopes of the hills immediately above the clay suffered very severely, and all on the Tertiary strata were more or less injured, whilst none of the buildings on the hippurite limestone or the basalt suffered any damage whatever,—the line at which the earthquake ceased to be destructive corresponding exactly with the boundary of the Tertiary beds.

strangers; the shops present little display, and are ill furnished with wares. The markets are tolerably well supplied with meat, fish, and country produce. A large quantity of excellent fruit is brought in for sale during the season.

The king usually resides at the palace of Ajuda, situate on a hill above the suburb of Belem. It is in the Italian style, and was intended to be one of the largest palaces in Europe, but it has been left incomplete. It contains a large library, a collection of pictures, and a numismatic cabinet. There is another royal palace at Lisbon (that of the Necessidades), where former monarchs were wont to reside, and in the neighbourhood of the city are numerous others. Several of the nobility have good and spacious houses in the city, which are dignified with the name of palaces.

The houses of the British residents are mostly to be found in the elevated district called Buenos Ayres.

Two or three small forts, one on a rock at the mouth of the Tagus, afford a very inadequate defence against the attacks of a hostile fleet. In ascending the river the picturesque Tower of Belem, built about the end of the 15th century, is seen on the north bank close to the water's edge. On a rocky hill stands the citadel of St George, surrounded by the most ancient part of Lisbon, composed of narrow tortuous streets, still retaining its old Moorish name, Alfama. The chief naval and military arsenals of the kingdom are at Lisbon. Attached to the former are a naval school and a hydrographical office. Here also is a museum of colonial products. In various parts of the city are barracks for the accommodation of the

FIG. 1.—Plan of Lisbon.

troops and for the municipal guard. The churches are numerous, but are nearly all in the same tasteless Italian style; the interiors, overlaid by heavy ornament, contain pictures utterly devoid of merit. The cathedral is gloomy without being grand, but the oldest part behind the high altar may deserve inspection. The largest church in the city is St Vincent's, 222 feet by 82. The large adjacent convent is now the residence of the cardinal patriarch. In a modern chapel attached to the church the coffined corpses of the monarchs of the house of Braganza are deposited, and the public are admitted to see them on certain days in the year. Perhaps the most striking church in Lisbon itself is that of the Estrela, with a dome commanding an extensive view, and two towers, the whole design reminding the visitor of St Paul's, London. At St Roque is the famous chapel of St John

the Baptist, designed by Vanvitelli, and made at Rome for King John V, who had been enriched by the discovery of the gold and diamond mines in Brazil. Before being sent to Portugal it was set up in St Peter's, and Benedict XIV. celebrated the first mass in it. It is composed of precious marbles with mosaics and ornaments in silver and bronze, and is said to have cost upwards of £120,000. By far the most interesting architectural object at Lisbon is, however, the unfinished Hieronymite church and monastery at Belem. The church was begun in 1500 near the spot where Vasco da Gama had embarked three years before on his famous voyage to India. The style is a curious mixture of Moorish Gothic and Renaissance, with beautiful details. The English college was founded in 1628 for the education of British Roman Catholics; and the Irish Dominicans have a chapel and convent originally established for the educa-

tion of youths intended for the priesthood. Ecclesiastically Lisbon is a patriarchate, the holder of the dignity being at the head of the clergy of the kingdom, and president of the chamber of peers. He is usually made a cardinal.

The two chambers of parliament hold their sittings in a huge building, formerly the monastery of St Bento, to which a handsome facade has been added. New and ornamental buildings have been erected for the courts of justice and the municipal chamber. The mint is fitted up with steam machinery on a small scale for coining gold, silver, and copper. Postage stamps and inland revenue stamps are printed at this establishment. The national astronomical observatory is near the Ajuda palace, and the meteorological observatory is at the Polytechnic school, which also contains the national museum of natural history. Here is a good collection of the birds of Portugal, with collections in other branches of the zoology of Portugal and the Portuguese possessions in Africa—minerals, fossils, &c. The fossils collected by the Geological Commission to illustrate the geology of the kingdom are preserved in the sequestered Convento do Jesus.

Lisbon is singularly destitute of works of high art. The gallery of the Academy of Fine Arts contains only a few pictures worth notice. In the custody of the academy is an interesting assemblage of gold and silver plate taken from suppressed monasteries. There is also a collection of pictures at the Ajuda palace. At the Carmo church is an archaeological museum. The great national library consists for the most part of old theological works and ecclesiastical histories swept out of various suppressed monasteries, and has a collection of 24,000 coins with some Roman bronzes. The Portuguese take little interest in literature, art, or science, and almost everything connected with them is in a neglected state. Literary and scientific societies are few in number and badly supported, the principal one being the Royal Academy of Sciences, founded in 1775. The national printing office, a Government establishment, turns out creditable work, but the booksellers' shops are few and ill-stocked. Eight or ten daily journals are published in Lisbon, and these are a few weekly newspapers, besides periodicals appearing at longer intervals, and chiefly devoted to special interests.

Several cemeteries have been constructed of late years near Lisbon, the practice of interring in churches having been abandoned. In the English cemetery lies the English novelist Fielding, who died here in 1754; a marble sarcophagus with a long Latin inscription covers his remains. The British residents maintain a chaplain who performs service regularly in an adjacent chapel, and the Scottish Presbyterians have also a place of meeting. The great hospital of St. José contains beds for nine hundred patients, and the large lunatic asylum has accommodation for four hundred patients. The Foundling Hospital takes in more than two thousand children annually. At Belem is an excellent establishment where a large number of male orphans and foundlings are fed, clothed, educated, and taught various trades. The Lazaretto is a vast building on the south side of the Tagus, where one thousand inmates can be received at one time.

Lisbon is connected by railway with Madrid, and there is also a line northward to Coimbra and Oporto, as well as lines southward to Setúbal, Évora, and Beja. Submarine cables connect it with England and with Brazil. There is communication by regular lines of steamers with the Portuguese islands in the Atlantic and the colonies in Africa, and with a great number of ports in Britain, continental Europe, and other parts of the world. Lisbon is the largest port in the kingdom, and its custom-house is a spacious and very substantial fire-proof building worthy of any capital in Europe, in which merchants are allowed to

deposit their goods free of duty for a year, or for two years in the case of Brazilian produce. The duties annually collected here exceed £1,150,000, tobacco alone producing £400,000. Upwards of 1400 foreign vessels, and about 1100 Portuguese ships, including coasters, enter the port annually. The annual imports amount to about £5,500,000, and the exports to £4,500,000. A considerable number of foreign merchants reside in Lisbon, and there are about fifty British firms. The most active commerce is carried on with Brazil and Great Britain, tropical produce being

FIG. 2.—Port of Lisbon.

imported from the one, and manufactured goods from the other, while wine and oil are sent to both in return. The wine for exportation is all made and stored outside the city bounds, so as not to be subject to the octroi duty. There are several joint-stock banks, one of them being British (the New London and Brazilian Bank), as well as private bankers. Manufactures are carried on only to a limited extent. The largest establishment by far is the tobacco manufactory, where 1600 persons are employed, and three millions of pounds are annually manufactured.

The chief supply of water, for the use of the city is brought by an aqueduct 9 miles in length, from springs situated on the north-west. This work, one of the bores of Lisbon, was completed in 1738, and was so well executed that the great earthquake did it no injury. It crosses the Alcantara valley on thirty-five arches, the principal one being 263 feet above its base, with a span of 110 feet. On reaching the city the water is conducted into a covered massive stone reservoir, which an inscription styles "urbis ornamentum orbis miraculum," and thence it flows to the fountains, thirty-one in number, distributed throughout the city. From these fountains it is removed in barrels to the houses by "Gallegos," men from Galicia, who do the principal part of the hard work in Lisbon. Although there are two other reservoirs near the city, the supply of water is insufficient for the requirements of the place during the warm season.

For municipal purposes the city is divided into four districts (*barros*), the whole under one municipal chamber, and two suburban districts under separate chambers. The city chamber consists of twelve members elected by the burgesses every two years. Its revenue is about £75,000. The octroi duties, levied on provisions and fuel entering the city, are collected on account of the Government, and exceed £270,000 a year. The police force is paid by the Government, and consists of the municipal guard, a military force of cavalry and infantry under the orders of the home secretary, and a body of ordinary policemen at the orders of the civil governor, an official appointed by Government. According to the census of 1878 the population in the thirty-nine parishes of the city and suburbs was 253,000.

Climate.—Notwithstanding the mildness of the climate, Lisbon is not considered a healthy place of residence, owing chiefly to the defective sanitary arrangements. The annual death-rate is 36 per thousand. The deaths are said to exceed the births, and the population would therefore decrease were the city not continually recruited from the country. To chest invalids it is not by

any means to be recommended as a winter resort, on account of the frequent and rapid changes of temperature to which it is subject. These changes, and the great difference between the temperatures of sun and shade during the winter and spring, are dangerous to the delicate. In summer the heat is great, and all who have the means betake themselves during that season to Cintra or to the seaside. The following data, deduced from twenty years' observations (1846 to 1875) taken at the Meteorological Observatory, a well-managed institution which stands 835 feet above the level of the sea, will afford the means of judging the climate in its principal features. Mean annual temperature of shade, 60° 27 Fahr., mean annual range, 61° 2, mean daily range, 12° 6; highest and lowest registered during the whole period, 95° 4 and 30° 8. Mean annual quantity of rain, 38.84 inches; greatest and least annual quantity during the period, 38.8 inches (1866) and 17.22 inches (1874). The rainfall of 1876, however, amounted to 45 inches, more than one-third of which fell in the month of December. The mean annual number of days on which rain fell was one hundred and twelve, whilst snow fell only three times during the twenty years. The mean atmospheric moisture (100-saturation) was 70.59. The mean annual height of the barometer was 29.8 inches, and its mean annual range 1.3 inches. The prevailing winds of the winter and autumn are from the north, of the spring and summer from the north-north-west.

History.—The name Lisbon (Portuguese, *Lisboa*) is a modification of the ancient name Olympe, also written Olyssippo under the influence of a mythical story of a city founded by Ulysses in Iberia, which, however, according to Strabo, was placed by ancient tradition rather in the mountains of Thracia than in Iberia. The Romans Olympe became a municipium with the epithet of Felicitas Julia, but was inferior in importance to the less ancient Emerita Augusta (Merida). After the Romans the Goths and the Molesims successively became masters of the town and district. Under the latter the town bore in Arabic the name of Lashib or Chaldish. It was the first point of Molesim Spain attacked by the Normans in the invasion of 844. When Alfonso I. of Portugal took advantage of the decline and fall of the Almoravid dynasty to incorporate the provinces of Estremadura and Alemberg in his new kingdom, Lisbon was the last city of Portugal to fall into his hands, and yielded only after a siege of several months (October 1147), with the aid of English and Flemish crusaders who were on their way to Syria. In 1164 the city was again attacked by the Molesims under the powerful caliph Abu Ya'qub, but the enterprise failed. In the reign of Ferdinand I., the greater part of the town was burned by the Castilian army under Alfonso (1173). Under the reign of the Castilians again besieged Lisbon, but without success. Lisbon became the seat of an archbishop in 1180, the seat of government in 1422. It gained much in wealth and splendour from the maritime enterprises that began with the voyage of Vasco da Gama (1497). The patriarchate dates from 1716. From 1680 to 1640 Lisbon was a provincial town under Spain, and it was from this port that the Spanish Armada sailed in 1588. In 1640 the town was captured by the duke of Braganza, and the independence of the kingdom restored. For many centuries the city had suffered from earthquakes, of more or less violence, but those had been almost forgotten when, on the 1st of November 1755, it was reduced almost in an instant to a heap of ruins. A fire broke out to complete the work of destruction, and between 80,000 and 40,000 persons lost their lives. Pombal, an unscrupulous minister, but a man of great talent, applied himself with unremitting energy both to the protection of the rights of property (for the place was infested by bands of robbers) and to the reconstruction of the buildings. The handsomest part of the present city was erected under his direction, but even to this day there are edifices which speak forcibly of the great earthquake. In 1807 Napoleon proclaimed that the house of Braganza had ceased to reign in Europe, whereupon the regent Don John (the mother the reigning queen Maria I. having become insane) thought it prudent to quit the country for Brazil, and next day a French army under Junot entered the city, possession of which he retained for ten months. He then quietly embarked his army under the protection of the inextinguishable conflagration of Cintra so close at hand as the English general Sir Arthur Wellesley was stricken by yellow fever, and many thousands were carried off before the plague was stayed. Lisbon boasts of having been the birthplace of St Anthony, surnamed of Padua, of Camoens, the national epic poet (to whose honour a bronze statue has been placed in one of the squares), and of Pombal (see XXI.).

LISBURN, a market-town, cathedral city, and municipal and parliamentary borough of Ulster, Ireland, partly in Antrim and partly in Down, is situated in a beautiful and fertile district on the Lagan, and on the Ulster Railway, 8 miles south-south-west of Belfast. It is substantially built, and consists principally of one long and irregular street, in the centre of which there is a large open space for the market. The parish church, which possesses a fine

octagonal tower, is the cathedral church of the united dioceses of Down, Connor, and Dromore, and contains a monument to Jeremy Taylor, who was bishop of the see. Among other buildings are the court-house, the market-house, the linen-hall, and the county infirmary. There are a number of charitable foundations. The staple manufacture of the town is linen, specially damasks and muslins. There are also bleaching and dyeing works. The population in 1871 was 9326, and in 1881 it was 10,834.

In the reign of James I. Lismur, which was then known as Lismagarry, was only an inconspicuous village, but in 1527 it was granted by Charles I. to Viscount Conway, who erected the castle for his residence, and laid the foundation of the prosperity of the town by the introduction of English and Welsh settlers. In November 1641 the town was taken by the insurgents, who on the approach of superior numbers set fire to it. The troops of Cromwell gained a victory near the town in 1649, and the castle surrendered to them in 1650. The church was constituted a cathedral by Charles II., from whom the town received the privilege of returning two members to parliament, but since the Union it has returned only one.

LISIEUX, capital of an arrondissement in the department of Calvados, France, 113 miles by rail west-north-west from Paris, and 24 miles as the crow flies east from Caen, is prettily situated on the Touques, at the point where it is joined by the Orbiquet, 24 miles above Trouville. The Paris and Caen Railway has a branch from Lisieux to Honfleur and Trouville, and another to Orbec. The cathedral church, dedicated to St Peter, founded about 1045, and finished in 1233, which has recently been restored, is the most interesting specimen to be found in Normandy of the transition from the Roman to the Ogival style. It is 360 feet in length, 90 in breadth, and 55 in height; the south tower rises to 230 feet. The nave is remarkable for harmony of proportion, purity of design, and unity of style. The church of St Jacques, built at the end of the 15th century, contains some beautiful glass of the Renaissance, some remarkable woodwork and old frescoes, and a curious picture on wood, restored in 1681. The old episcopal palace (Lisieux ceased to be a bishopric in 1801) near the cathedral is now used as a court-house and prison. In the court-house is a beautiful hall called the Salle Dorée. The town still retains quaint examples of the wooden houses of the 14th, 15th, and 16th centuries; and there are some elegant modern villas. It also possesses a charming public garden and a small museum. The confluence of the two rivers renders it subject to disastrous inundations; but its commerce and industry cause it, notwithstanding, to rank among the richest towns of Normandy. There is a large cattle trade, and the arrondissement has nearly three hundred factories, employing about ten thousand workmen in the manufacture of cloth and crotches. Connected with this industry are numerous spinning-mills, bleaching-fields, and dye-works; and there are besides wool-mills, chemical works, tanneries, saw-mills, and the like, which bring up the trade of Lisieux to an annual aggregate of upwards of 50 million francs. The population in 1876 was 18,400.

In the time of Caesar, Lisieux, by the name of *Noviomagus*, was the capital of the Lexovii. Though destroyed by the barbarians, by the 6th century it had become one of the most important towns of Neustria. In 680 it was sold to date from the 8th or 9th century. In 877 it was pillaged by the Normans, and in 911 we find it included in the duchy by the treaty of St. Clair-sur-Epte. Civil authority was exercised by the bishop as count of the town. In 1136 Geoffrey Plantagenet laid siege to Lisieux, which had taken the side of Stephen of Blois. The war lasted five years, and reduced Lisieux and its neighbourhood to the direst extremities of famine. In 1155 the marriage of Henry II. of England to Eleanor of Guienne, which added so largely to his dominions, was celebrated in the cathedral. Thomas à Becket took refuge here, and some vestments used by him are still shown in the hospital chapel. Taken by Philip Augustus and reunited to France in 1200, the town was a frequent subject of dispute between the contending parties during the Hundred Years' War, the religious wars, and those of the League.

Among the bishops of Lisieux may be mentioned Nicholas Oresme, who died in 1382, and Pierre Cauchon, the judge of Jean of Arc, who occupied this see after he had been driven from that of Beauvais.

LISKEARD, anciently LISCARRETT, a market-town and municipal and parliamentary borough in the county of Cornwall, England, is picturesquely situated, partly in a hollow and partly on a rocky eminence, 12 miles east of Bodmin, and 265 west-south-west of London by rail. The church of St Martin, in the Perpendicular style, with a tower of earlier date which possesses a Norman arch, is the largest ecclesiastical building in the county, except the church of Bodmin. A town-hall in the Italian style was erected in 1859. A grammar school was founded at a very early period, and there are several other schools and charities. There are manufactures of leather, but the prosperity of the town is dependent chiefly on agriculture, and the neighbouring tin, lead, and copper mines. Liskeard returns one member to parliament. It received its first charter in 1240, from Richard, earl of Cornwall, brother of Henry III., but its principal charter in 1586, from Queen Elizabeth. The population of the municipal borough (area 810 acres) in 1871 was 4700, and in 1881 it was 4478, that of the parliamentary borough (area 8387 acres) in the same years being 6576 and 5591.

LISLE, JOSEPH NICOLAS DU (1698-1768), astronomer, was born at Paris on April 4, 1698, and was educated at the Collège Mazarin. His devotion to astronomy dates from 1706, in which year he carefully observed an eclipse of the sun. In 1714 he was admitted to the Academy of Sciences, and in 1720 he made the proposals for determining the figure of the earth, which were carried out under the auspices of that body some years afterwards. In 1724 De Lisle visited England, where, through Newton and Halley, he was received into the Royal Society, and in 1726 he accepted an invitation from Catherine I. to the chair of astronomy in the Imperial Academy of Sciences at St Petersburg. In 1747 he returned to Paris, and was allowed a very imperfect observatory in the Hôtel Clugny, where Messier and Lalande were among his pupils. In 1753, previous to the transit of Mercury, he published a map of the world representing the effect of that planet's parallaxes in different countries, and in 1754 he was made geographical astronomer to the naval department. In 1762 he resigned in favour of Lalande, and withdrew to the abbey of Sainte Geneviève, where he died of apoplexy on September 11, 1768.

Besides numerous papers contributed to the *Transactions* of the Académie de Paris, Berlin, and St Petersburg, he wrote *Mémoires pour servir à l'histoire et aux progrès de l'astronomie, de la géographie, et de la physique* (St Petersburg, 1738), *Séances et communications, ad années 1784, 1788, et années précédentes 1789* (Berlin, 1784), and *Mémoires sur les nouvelles découvertes au nord de la mer du Sud* (Paris, 1762-58). See *Astronomy*, vol. ii p. 757.

LISMORE, an island of 9600 acres, about 10 miles long and averaging 1½ miles broad, with a population in 1881 of 630, lying south-west and north-east at the entrance of the Linnhe Loch in Argyllshire, Scotland. The name means the great enclosure (whether "garden," as the Scotch, or "fort," as the Irish authorities suppose, is uncertain), and occurs in Ireland in the Waterford Lismore and ten other places. "Lis" is one of the most frequent words in compound Irish names, there being one thousand four hundred townlands or villages which begin with it. A Columban monastery was founded there by St Moluag about 593 (Reeves, *Adamnan*, p. 34), whose bell is perhaps that found in 1814 at Kilnichol Glassary,¹ and whose crozier or staff is in the possession of the duke of

Argyll.² About 1200 the see of Argyll was separated from Dunkeld by Bishop John "the Englishman," and Lismore soon after became the seat of the bishop of Argyll, sometimes called "Episcopus Lismoriensis" (Skene, *Celtic Scotland*, n. p. 408 *sq.*), quite distinct from the bishop of the Isles (Sudreys and Isle of Man), called "Episcopus Sodorienus" or "Insularum," whose see was divided into the English bishopric of Sodor and Man and the Scottish bishopric of the Isles in the 14th century (Keith's *Catalogue*, p. 173). The monastic establishment of Lismore, at one time consisting of Culdees (Reeves, *Culdees*, p. 49), was converted into a chapter of canons regular and a dean, whose right to elect the bishop was recognized as early as 1249 (Baluze, *Miscel.*, vii p. 442; *Orig. Paroch. Scot.*, ii. pt. 1, p. 181).

Lismore has an accidental celebrity from the *Book of the Dean of Lismore*, a MS. collection of poems, Gaelic and English, made by James M'Gregor, vicar of Fortingall and dean of Lismore (1614-61). A selection of the Gaelic poems, with translations by Rev. T. M'Lauchlan, and introduction by Mr W. F. Skene, published 1862, is of value both for the language and the contents. The language is the Gaelic of the West Highlands, spelt phonetically, as spoken in the beginning of the 16th century, and its variations from ancient Irish on the one hand and modern Gaelic on the other are of much interest to Celtic scholars. Its contents are Ossianic fragments, some of Irish, others of Scotch origin, and a few more recent Gaelic verses. The publication of this work, and J. F. Campbell of Inverary's collection from oral sources of the existing traditional Gaelic poetry, have for the first time given a genuine historical solution of the Ossianic problem (see *Ossian*). There are remains of three castles on Lismore—at Turefort a fort of two concentric circles of dry stones, supposed to be Norse or Danish; at Achdundun a square keep with walls 40 feet high, believed to be the palace of the bishop; and on the west end of the island Castle Corrin, mentioned in a grant to Campbell of Glenmuiray in 1470 (*Orig. Feud. Sc.*, n. p. 109).

LISMORE, a market-town and seat of a diocese, partly in Cork but chiefly in Waterford, Ireland, is beautifully situated on a steep eminence rising abruptly from the Blackwater, 40 miles west-south-west of Waterford. At the verge of the rock on the western side is the old baronial castle, erected by King John in 1185, which was the residence of the bishops till the 16th century. It was besieged in 1641 and 1643, and in 1645 it was partly destroyed by fire. To the east, on the summit of the height, is the cathedral of St Carthage, erected in 1663 by the earl of Cork, in the Later English style, with a square tower surmounted by a tapering spire. There are a grammar school, a free school, and a number of charities. Some trade is carried on by means of the river, and there is a salmon fishery. The population of the town in 1871 was 1945.

The original name of Lismore was Magheasteth. Its present name was derived from a monastery, founded by St Carthage in 683, which became so celebrated as a seat of learning that it is said no less than twenty churches were erected in its vicinity. In the 9th and beginning of the 10th centuries the town was repeatedly plundered by the Danes, and in 978 the town and abbey were burned by the Ossianians. Henry II., after landing at Waterford, recaptured in Lismore castle the allegiance of the archbishops and bishops of Ireland. In 1518 the manor was granted to Sir Walter Raleigh, from whom it passed to Sir Richard Boyle, afterwards earl of Cork. From the earl of Cork it descended by marriage to the duke of Devonshire. It was incorporated as a municipal borough in the time of Charles I., when it also received the privilege of returning members to parliament, but at the Union it was disfranchised, and also ceased to exercise its municipal functions. Lismore is the birthplace of Robert Boyle, but its claim to be the birthplace of Congress does not rest on a sufficient foundation.

LISSA (in Polish, *Lesna*), a manufacturing town in the circle of Fraustadt, district of Posen, Prussia, is situated on the Breslau and Posen Railway, near the frontier of Silesia. The most prominent buildings are the handsome château, the mediæval town-house, the three churches, and the synagogue. Its manufactures consist chiefly of cloth, liqueurs, tobacco, and wax; it also

¹ Anderson, *Scotland in Early Christian Times*, 1st ser., p. 206, where it is figured.

² See *Orig. Paroch. Scot.*, where it is figured.

possesses several tanneries and a large steam flour-mill, and carries on a brisk trade in grain, cattle, spirits, wine, and furs. The population in 1880 was 11,758, including 3810 Roman Catholics and 1839 Jews.

Lissa owes its origin to a number of Moravian Brothers from Bohemia, who were banished by the emperor Ferdinand I in the 16th century, and found a refuge on the estate of the Polish family of Łęczyński. Their settlement received municipal rights in 1546. During the Thirty Years' War the population was reinforced by other refugees, and Lissa became an important commercial town, and the chief seat of the Moravian Brothers in Poland. COZZIUS (q.v.) was first rector of the celebrated Moravian school there. Lissa was twice burned down (in 1666 and 1707) during the Swedish and Polish wars.

LISSA (Lat., *Lissa*, Slav, *Vše*), an Austrian island in the Adriatic, 9 miles long, with a greatest breadth of 4 miles, is situated 41 miles from the coast of southern Dalmatia, almost due west of the mouth of the Neretva, in 43° 1' N. lat. and 16° 6' E. long. "The shape is one of the finest harbours of refuge in the Adriatic" on the eastern short side, and the Vallone di Comisa contained between two long prongs stretching due west and south-west. The outer walls are stony ridges rising from 470 to 610 feet above sea-level, and declining quaquaversally to the fertile plateau which, averaging 400 feet high, forms the body of the island. The apex is Monte Hum, a bald and flattened cone (1868 feet) on the south-west" (Burton). Wine-growing (for which Lissa was famous of old) still forms the principal means of subsistence, an average season yielding from 70,000 to 80,000 barrels; but the sardine fishery (15,000 to 25,000 barrels per annum) is of growing importance, and the peasants distil about 24,000 lb of rosemary oil annually. The island is divided into two communes, Lissa and Comisa. In the former is the chief town, Lissa, with the palace of the old Venetian counts Gariboldi, the former residence of the English governor, the monastery of the Minorites, and at a little distance to the west the ruins of the ancient city of Issa. The population, 6485 in 1869, was 7871 in 1880.

Lissa is said to have been settled by people from Lesbos, the Issa of the *Ægean*. The Patene, assisted by Dionysius the Elder of Syracuse, introduced a colony in the 4th century B.C. During the First Punic War the Issians with their beaked ships helped the Roman Daulias, and the great republic, having defeated their island against the attacks of Agron of Illyria and his queen Teuta, again found them faithful and serviceable allies in the war with Philip of Macedon. As early as 996 we find the Venetians in possession of the island, and, though they retired for a time before the Ragusians, their power was effectually established in 1278. Velo Solo, which by that time had become the chief settlement, was destroyed by Ferdinand of Naples in 1488, and by the Turks in 1671. The present city arose shortly afterwards. During the Napoleonic wars Lissa was occupied by the French, but the English defeated their squadron in 1810, and kept possession of the island till July 1815, evicting the French (disarmed in 1870) and making it a centre of operations. In 1866 the Italians under Persano made an attack on Lissa, but were defeated by the Austrians under Tegethoff—the battle being fought about 10 miles north of the harbour.

LISTON, JOHN (1776–1846), comedian, was the son of a watchmaker in Soho, London, where he was born in 1776. While the teacher of a day school near Leicester Square, he began to take part in private theatricals, and soon conceived a passion for the stage. He made his debut at a small theatre in the Strand, and shortly afterwards obtained an engagement at Dublin theatre, where, although he adopted tragedy as his role, his natural talent for acting attracted the attention of Stephen Kemble, who engaged him for his theatre at Newcastle-on-Tyne. Discovering accidentally that his forte was not tragedy but comedy, Liston displayed in his personation of old men and country boys a fund of drollery and humour which proved irresistible. An introduction to Charles Kemble led to his

appearance at the Haymarket in 1805 as Zerkel Homespun, and from this time he occupied an unrivalled position in his own line of performance, his broad humour being tempered by true artistic finish, while he possessed an original power of creation which, with his boundless facility in the elaboration of absurdities, filled up meagre and commonplace outlines with the characteristics of vivid individuality. Paul Pry, first represented in 1825, and always his most popular part, soon became to many a real personage. Liston played successively at Covent Garden, Drury Lane, and the Olympic, and remained on the stage till almost the close of his life. He died March 22, 1846.

LISTON, ROBERT (1794–1847), an eminent Scottish surgeon, was born on the 28th of October 1794, at Ecclefechan, where his father was parish minister. He commenced the study of anatomy under Dr Barclay in Edinburgh University in 1810, and soon became a skilful anatomist. After eight years' study, he began his career as a lecturer on anatomy and surgery in the Edinburgh School of Medicine; and in 1827 he was elected one of the surgeons to the Royal Infirmary. In 1835 he was invited to fill the chair of clinical surgery in University College, London. He held the appointment until his death, on the 7th of December 1847. Liston was a teacher more by what he did than by what he said. He taught simplicity in all operative procedures, fertile in expedients, of great nerve, and of powerful frame, his name is remembered at the present day as a bold and rapid operator. He inspired all around with confidence, and every one present at his operations felt that the knife in his hands, however rapidly he worked, was guided with skill founded upon knowledge. He was the author of *The Elements of Surgery and Practical Surgery*, and made several improvements in methods of amputation, and in the dressing of wounds.

LITANY. This word (*litaneia*), like *λητή* (both from *litaein*), is used by Eusebius and Chrysostom, most commonly in the plural, in a quite general sense, to denote a prayer, or prayers, of any sort whatever, whether public or private; it is similarly employed in the law of Arcadius (*Cod. Theod.*, xvi. tit. 5, leg. 30), which forbids heretics to hold assemblies in the city "ad litaneia faciendam." But some trace of a more technical meaning is found in the epistle (*Ep.* 63) of Basil to the church of Neocaesarea, in which he argues, against those who were objecting to certain innovations, that neither were "Litaneia" used in the time of Gregory Thaumaturgus. The nature of the recently introduced litaneia, which must be assumed to have been practised at Neocaesarea in Basil's day, can only be vaguely conjectured; probably they had many points in common with the "rogations," which, according to Sidonius Apollinaris, had been gradually coming into occasional use in France about the beginning of the 5th century, especially when rain or fine weather was desired, and which, so far as the three fast days before Ascension were concerned, were first definitely fixed, for one particular district at least, by Mamertus or Mamerus of Vienne (c. 460 A.D.). We gather that they were penitential and intercessory prayers offered by the community while going about in procession, fasting, and clothed in sackcloth. Sidonius alludes to the incongruity of men going "castorinati ad litaneia." In the following century the manner of making litaneia (litaneia facere) was to some extent regulated for the entire Eastern empire by one of the *Novels* of Justinian, which forbade their celebration without the presence of the bishops and clergy, and ordered that the crosses (which were carried about in procession) should not be deposited elsewhere than in churches, nor be carried by any but such persons as were duly appointed to do so. The first synod of Orleans (511 A.D.) in its twenty-seventh canon enjoins

for all Gaul that the "litanies" before Ascension be celebrated for three days; on these days all menials are to be exempt from work, so that every one may be free to attend divine service. The diet is to be the same as in Quadragesima; clerks not observing these rogations are to be punished by the bishop. In 617 A.D. the synod of Gerunda provided for two sets of "litanies"; the first was to be observed for three days (from Thursday to Saturday) in the week after Pentecost with fasting, the second for three days from November 1. A synod of Paris (573) in its tenth canon ordered litanies to be held for three days at the beginning of Lent, and the fifth synod of Toledo (636) appointed litanies to be observed throughout the kingdom for three whole days from December 14. The first mention of the word *litany* in connexion with the Roman Church goes back to the pontificate of Pelagius I. (555), but implies that the thing was at that time already old. In 590 Gregory I., moved by the pestilence which had followed an inundation, ordered a "litania septiformis," that is to say, a sevenfold procession of clergy, laity, monks, virgins, matrons, widows, poor, and children. He is said also to have appointed the processions or litanies of April 25 (St. Mark's day), which seem to have come in the place of the ceremonies of the old Robigalia. In 747 the synod of Cloveshoe (can. 16 and 17) ordered the litanies or rogations to be gone about by all the clergy and people with great reverence,—on April 25 "after the manner of the Roman Church," and on the three days before Ascension "after the manner of our ancestors." The latter are still known in the English Church as Rogation Days. Games, horse racing, junketings were forbidden, and in the litanies the name of Augustine was to be inserted after that of Gregory. The reforming synod of Mainz in 813 ordered the major litany to be observed by all for three days, not with horses or in magnificent attire, but in sackcloth and ashes, and barefoot. The sick only were exempted from this command.

As regards the form of words prescribed for use in these "litanies" or "supplications," documentary evidence is somewhat defective. Sometimes it would appear that the "procession" or "litany" did nothing else but chant "Kyrie eleison" without variation. There is no reason to doubt that from an early period the special written litanies of the various churches all showed the common features which are now regarded as essential to a litany, in as far as they consisted of (1) invocations, (2) deprecations, (3) intercessions, (4) supplications. But in details they must have varied immensely. The offices of the Roman Catholic Church at present recognize two litanies, the "Litanie majores" and the "Litanie breves," which differ from one another chiefly in respect of the fulness with which details are entered upon under each of the four heads mentioned above. It is said that in the time of Charlemagne the angels Orithel, Raguel, Tobiel were invoked, but the names were removed by Pope Zacharias as really belonging to demons. In some medieval litanies there were special invocations of S. Sapientia, S. Fides, S. Spes, S. Charitas. The major litanies, as given in the Breviary, are at present appointed to be recited on bended knees, along with the penitential psalms, in all the six week days of Lent when ordinary service is held. Without the psalms they are said on the feast of Saint Mark and on the three rogation days. They are also chanted in procession before mass on Holy Saturday. The "litany" or "general supplication" of the Church of England, which is appointed "to be sung or said after morning prayer upon Sundays, Wednesdays, and Fridays, and at other times when it shall be commanded by the ordinary," closely follows the "Litanie majores" of the Breviary, the invocations of saints being of course omitted. A very similar German litany will be found in

the works of Luther. In the Roman Church there are a number of special litanies peculiar to particular localities or orders, such as the "Litanies of Mary" or the "Litanies of the Sacred Name of Jesus."

LITHGOW, WILLIAM (c. 1583–c. 1660), a noted Scottish traveller, was born in Lanark, where his father was a bargess, possessed of considerable horthable property. The date generally assigned to his birth is 1583, and he was educated at the grammar school of his native town, then celebrated as a seminary of learning. His natural disposition was probably active and restless, as even in his boyhood he tells us that he made voyages to both the Orkneys and the Shetlands, and somewhat later travelled through the Low Countries, Germany, Bohemia, and Switzerland. The final impelling cause of his leaving Scotland, however, appears to have been some savage outrage committed either upon himself or on one nearly connected with him, arising, it is thought, from some love affair, which gave him an intolerable disgust to home. He left his native country about 1608 or 1609, and proceeded to Paris, where he remained ten months, and then crossed the Alps to Rome and Naples; after which he wandered through Istria, Dalmatia, Albania, Greece, Asia Minor, Syria, Mesopotamia, Palestine, and Egypt, most of his journey having been performed on foot. In the course of his travels he escaped innumerable dangers from robbers, and hardships from exposure to inclement weather. He returned to England by Sicily and Paris. Another tour which he made lay through Morocco, Algiers, Tunis, Tripoli, Hungary, Germany, and Poland. On his arrival in London he became an object of interest to King James, who, on the spirit of travel again returning upon him, furnished him with commendatory letters to all kings, princes, dukes, &c., whose territories he might desire to visit. In 1619, accordingly, he went over to France, and thence passed through Portugal and Spain as far as Malaga. There he was apprehended as a spy, and after suffering the most excruciating torture, first in prison and afterwards in the Inquisition, he was at length released on the interference of the English consul, and allowed to return to England in 1621. The minute description which he gives of the terrible torture to which he was subjected is almost unequalled for horror, and, when he arrived in London, he had the appearance of a man more dead than alive. He was carried on a feather bed to Theobald's in order that King James might be an eyewitness of what he called his "martyred anatomy." The whole court crowded to see him. The king commanded that the greatest care should be taken of him, and he was twice sent to Bath at his Majesty's expense. On recovering his health, he was desired by James to apply to Gondomar, the Spanish ambassador, for recovery of the money and other valuables of which he had been plundered by the governor of Malaga, and for a thousand pounds in reparation of his injuries. Gondomar gave fair promises that all his demands should be granted, but nothing was done. Whereupon, having met the ambassador at the royal levee, and reproached him with his perfidy, after high words on both sides, Lithgow furiously assailed him with his fists, in the presence of the king, the imperial ambassador, and the knights and gentlemen of the court. This, of course, was an offence which could not be passed over, and, though his boldness was generally commended, he had to suffer an imprisonment of nine weeks in the Marshalsea. His latter years are understood to have been spent in his native town, and he is said to have died somewhere about 1660.

A portion of his travels appeared in a small volume in London in 1614, but the complete work was not published till 1682. It has been repeatedly reprinted. It was also translated into Dutch and published at Amsterdam in his lifetime. His other works are—*An Account of the Siege of Breida* (1687) at which he had been

present; *A Survey of London and England's State, 1645*. *Relation of the Steps of Newcastle, 1645*. His posthumous remains, collected by James Maidment, were published at Edinburgh in 1863.

LITHIUM, one of the rarer metallic elements, intermediate in its character between sodium and barium. It was discovered in 1817 by Arfvedson in the course of an analysis of petalite in Berzelius's laboratory. He recognized the presence in this mineral of a new kind of alkali, which his master subsequently named "lithium," to denote its mineral origin. Lithium, though widely disseminated throughout the mineral world—traces of it being found in almost all alkaliferous minerals, in the soils derived from these, and in many mineral waters—nowhere occurs in any abundance, except in the immense masses of lithia-mica (lepidolite) known to exist in Bohemia. Of other lithia-minerals (all rare) we may name petalite and spodumene (both silicates of alumina and alkalies) and triphylite, a mixed phosphate of ferrous, manganous, and lithium oxides. Only lepidolite comes into consideration as a raw material for the preparation of lithia and its salts. But the extraction from it of pure lithia in any form is difficult. The first step is the disintegration of the finely powdered mineral, which may be effected by means of nitric and hydrofluoric acid (or vitriol and fluor-spar); the silicon goes off as gaseous fluoride, the bases remain as sulphates. Or else we may mix the mineral intimately with quicklime, and by very intense heating of the mixture produce a more highly basic silicate, which is readily disintegratable by acids. In either case it is added to unite all the bases (Al_2O_3 , Fe_2O_3 , CaO , MgO , Li_2O , K_2O , Na_2O) into a solution of chlorides or sulphates. From it we precipitate successively and remove by filtration (1) the bases not alkalies or Li_2O by means of excess of milk of lime, and (2) the lime introduced by operation (1) by means of carbonate of ammonia. There results a mixed solution of potash, soda, lithia, and ammoniac salt, from which the last-named component is easily removed by evaporation to dryness and ignition. For these very tedious operations Troost has substituted an elegant process which, though admittedly imperfect in the analytic sense, lends itself admirably to manufacturing purposes. He mixes ten parts of the finely powdered mineral with ten parts of carbonate of baryta, five parts of sulphate of baryta, and three parts of sulphate of potash, and melts down the mixture in a powerful wind-furnace. There results a mass which separates spontaneously into a lower layer forming a transparent glass, and an upper one consisting of the sulphates of barium, potassium (sodium), and lithium, the latter representing about three-fourths of the lithia contained in the mineral. By treatment with water the sulphate of baryta is easily removed as an insoluble residue; the mixed alkaline sulphates are converted into chlorides by decomposition with chloride of barium, and from the dry mixed chlorides approximately pure chloride of lithium is obtained by lixiviation with ether-alcohol, which solvent dissolves only very small proportions of the other chlorides. To purify the crude chloride it is dissolved in water and, by double decomposition with carbonate of soda, converted into a precipitate of carbonate of lithia, Li_2CO_3 , which must be washed with small instalments of water, as it is very appreciably soluble in water. This carbonate of lithia is still contaminated with soda. To purify it fully dissolve it in water with the help of carbonic acid, filter, and evaporate slowly on a water-bath; the added carbonic acid goes off, and pure carbonate of lithia separates out in crystalline crusts (Troost). One liure of pure water dissolves 12 grammes; 1 litre of water kept saturated with carbonate lithia dissolves 52.5 grammes of the carbonate. The dry salt fuses at a red heat, but before cooling it shows no of its carbonic acid, which, after cooling, it shows no

tendency to take up again from the atmosphere. Perfectly acid-free lithia, Li_2O , can be obtained by heating a mixture of the carbonate and pure charcoal in a platinum crucible, or by heating the nitrate for a long time in a silver one. If the preparation, ultimately, of the hydrate $Li_2O.H_2O = 2LiOH$ is contemplated, the latter operation may be very materially shortened by addition of metallic copper, which reduces the nitric acid. The anhydrous oxide, when treated with water, dissolves without much evolution of heat as hydrate, $LiOH$, which, by evaporation (in silver) is easily obtained in the solid form. It melts at a dull red heat, but at even higher temperatures loses no water. It dissolves in water (far less abundantly than soda), with formation of a strongly alkaline solution, which neutralizes all acids, with formation of salts. Like baryta, it refuses to form acid sulphates or carbonates (the bodies $HLiSO_4$ and $HLiCO_3$ exist only in solution), and forms insoluble or almost insoluble salts with carbonic and phosphoric acids (formulas Li_2CO_3 and Li_2PO_4); and, last not least, it is not reducible to metal by charcoal at any temperature. Add to this that the highly deliquescent chloride $LiCl$, when dehydrated by heating, always loses part of its chlorine as HCl , and we feel tempted to conclude that in the case of lithium, as in that of barium or magnesium, two equivalents are united into one atom $Li = Li_2 = 14$. But the specific heat of the metal demands the lesser number.¹

Metalline Lithium, although long before known to exist, was successfully prepared for the first time in 1855, by Bunsen. He obtained it by fusing the pure chloride in a porcelain crucible, and decomposing the fused salt by a battery of four or six "Bunsens," using a rod of retort charcoal as a positive and a knitting wire as a negative pole. The metal separates out in about pea-sized globules, which stick to the wire, and, thanks to the protecting action of the fused chloride, can be lifted out and collected without reoxidation, under rock-oil. Lithium is a silver-white metal, of only .68 specific gravity (it floats on rock-oil), somewhat softer than lead, and like it susceptible of being pressed into wire. It tarnishes in air, though far less readily than sodium. When thrown upon water it gradually dissolves as hydrate, with evolution of hydrogen, but without fusing. The metal melts at $180^\circ C$, and at a somewhat higher temperature takes fire and burns into oxide with a brilliant white flame. Hence the characteristic intensely red colour which a colourless gas flame assumes when a lithium salt is volatilized in it must be a property of something else than the metal itself; perhaps it is the hydroxide $LiOH$ that emits it. The red lithium flame forms a spectrum consisting chiefly of one brilliant red and a somewhat faint orange line.

Lithia-salt solutions behave to general reagents pretty much like those of potash or soda, from which, however, they differ in the following points—(1) concentrated solutions are precipitated by carbonate of potash or soda; (2) even dilute solutions when mixed with phosphate of soda and caustic soda, in the heat more readily, give precipitates of the phosphate PO_4Li_3 , soluble in 2040 parts of plain, and in 8900 parts of ammoniac water, more largely in solutions of ammoniac salts; (3) unlike potassium salts, they give no precipitate with chloride of platinum. (W. D.)

LITHOGRAPHY. The principle upon which the art of lithography is based is very simple—the antagonistic qualities of grease and water. An unctuous composition is made to adhere to a peculiar kind of limestone; the parts thus covered acquire the power of receiving printing ink; the other parts are prevented from receiving it by the interposition of a film of water; and then by pressing paper strongly upon the stone impressions are obtained. There are two distinct branches in lithography—drawing and printing. Those practising the first are known as lithographic draughtsmen or writers, the second as lithographic printers.

The art of lithography was discovered by Alois Senefelder, a native of Prague, born 6th November 1771. His father, Peter Senefelder, was one of the performers of

¹ Lithia oxide and carbonate were long supposed to exert a characteristically powerful corrosive action on platinum vessels used for their fusion. This, according to Troost, holds only for such preparations as are contaminated with rubidia or caesia. The pure lithia compounds, even the oxide (and hydrate), do not attack platinum.

the Theatre Royal at Munich. The son Alois wished to follow the same profession, but, his father being opposed to this, he went to the university of Ingolstadt, and devoted himself to the study of jurisprudence. Owing to the death of his father shortly afterwards, he was unable to continue his studies at the university, and, yielding to his old inclination, he tried to support himself as a performer and author, but without success. In order to accelerate the publication of one of his works, he frequently spent whole days in the printing office, and thus became acquainted with all the particulars of the process of printing. It appeared so simple that he conceived the idea of purchasing a small printing press, thus enabling himself to print and publish his own compositions; but his means were inadequate, and to this circumstance we probably owe the invention of lithography. Unable to pay for the engraving of his compositions, he attempted to engrave them himself. He tried numerous experiments with little success; tools and skill were alike wanting. Copper-plates were expensive, and the want of a sufficient number entailed the tedious process of grinding and polishing afresh those he had used. About this period his attention was accidentally directed to a fine piece of Kollheim stone which he had purchased for the purpose of grinding his ink. His first idea was to use it merely for practice in his exercises in writing backwards, the ease with which the stone could be ground and polished afresh being the chief inducement. The idea of being able to take impressions from the stone had not yet occurred to him. While he was engaged one day in polishing a stone slab on which to continue his exercises, his mother entered the room and desired him to write her a bill for the washer-woman, who was waiting for the linen. Neither paper nor ink being at hand, the bill was written on the stone he had just polished. The ink used was composed of wax, soap, and lamp-black. Some time afterwards, when about to wipe the writing from the stone, the idea all at once struck him to try the effect of biting the stone with aqua fortis. If the parts written on resisted its action, impressions might then be taken in the same way as from wood engravings. Surrounding the stone with a border of wax, he covered its surface with a mixture of one part of aqua fortis and ten parts of water. The result of the experiment was that at the end of five minutes he found the writing elevated about the tenth part of a line ($\frac{1}{10}$ inch). He then proceeded to apply the printing ink to the stone, using at first a common printer's ball, but soon found that a thin piece of board covered with fine cloth answered better, communicating the ink more equally. He was able to take satisfactory impressions, and, the method of printing being new, he hoped to obtain a patent for it, or even some assistance from the Government. For years Sensfelder continued his experiments, until the art not only became simplified, but reached a high degree of excellence in his hands. In later years the king of Bavaria settled a handsome pension on Sensfelder. He died at Munich in 1834, having lived to see his invention brought to comparative perfection.

Materials Employed by the Lithographic Artist.—Lithographic stones are very compact homogeneous limestones, imported chiefly from Germany. The traffic has its centre in the village of Solenhofen, in the district of Monheim. The Solenhofen stone, in its chemical decomposition, consists of lime and carbonic acid. It is generally cut in slabs from 2 to 3 inches in thickness, and is sold by weight. Stones yielding impressions in the lithographic press have been found in England, France, Italy, Canada, and the West Indies; but all are much inferior to the best German stones. Lithographic stones vary in colour from a dull grey or yellow to a light creamy shade, the dark

grey stones being the hardest. They are sometimes uneven in colour, having light and dark patches. These are suitable for ordinary transfer work; but, in cases where the artist requires to see the effect he is producing during progress (as in chalk drawing), stones of an even grey or drab colour should be selected.

Lithographic ink is composed of tallow (4 oz.), wax (5 oz.), soap (4 oz.), shellac (3 oz.), and *quant. suff.* of fine Paris black. The inks of Lemercier and Vanhymbeek are generally considered as among the best. Lithographic chalk is made in the same manner as the ink, but requires to be burnt sufficiently hard for use in drawing. Excellent lithographic crayons are manufactured by Lemercier of Paris. They are made of several degrees of hardness, copal chalk, used for outlining, being the hardest.

Transfer paper for writing and drawing is prepared by coating the surface of the paper with a composition of size, made from parchment cuttings and flake white. Sometimes the coating is composed of starch and glue. Colouring matter, generally gamboge, is added, the object being to show more readily which is the coated side of the paper. The coating is applied with a flat brush. For writing, the paper used is thin, for drawing it is thicker; for large subjects ordinary drawing paper is used. It is afterwards glazed by being pulled through the lithographic press, face down, on a smooth stone, or hot pressed. There are several other varieties of transfer papers—a transparent or tracing paper, and a transfer paper for chalk drawing, having a finely granulated surface. Mr Nelson of Edinburgh patented a method of graining transfer paper by means of stippled plates. The older method was to press the coated surface of the paper on an ordinary sand-grained stone or plate.

Instruments and Appliances used in Lithographic Drawing and Writing.—For the finer purposes of lithography ordinary steel pens are useless; "Perry's lithographic pen" may be found serviceable when the work is not very delicate. Transfer writers prefer pens of their own making. These are either made from quills scraped down, before cutting, with a piece of broken glass, until the barrel yields to pressure of the nail, or cut with a pair of sharp scissors from thin sheets of steel prepared for the purpose. This operation is difficult, and requires much skill and practice. Pens are also made of watch springs, reduced to the necessary tenuity by nitric acid and water.

Lithographic brushes are made from red sable crowquill pencils; a portion of the hair is cut away all round, and only the central part of the brush is used.

Scrapers are employed in correcting the work upon stone, but a penknife or ordinary erasing knife answers the purpose equally well.

Crayon holders of the ordinary kind may be used for lithographic chalk. When cut in two and fitted with a wooden handle, they will be found lighter and pleasanter to work with.

The hand-board is a piece of wood about 6 inches wide, three-eighths of an inch thick, and somewhat longer than the stone on which the draughtsman works. It rests upon thick strips of millboard fixed round the edges of the stone, to keep it from touching the part to be drawn on.

Ruling and circle pens, parallel rulers, tracing paper, a tracing point, and red tracing paper, for transferring tracings to paper or stone, are also requisites.

Drawing on Stone—The Chalk Method.—For artistic purposes this is perhaps the most important and interesting department of lithography. In preparing the stone for chalk drawing, the surface, instead of being polished, is broken up into minute points or "grained." The coarseness or fineness of the grain is varied according to the work to be done. A hard stone, free from veins, marks, and chalk

spots, and of a clear grey colour, is selected. It is first ground and pumiced to free it from scratches. A small quantity of the finest gravel sand, or "graining sand," is sprinkled over the surface, and a few drops of water added; a smaller stone of the same size and hardness is placed above, face downwards, and moved about with a circular motion, water is added from time to time, and fresh sand when needed. Care must be taken that no scratches are caused by grains of coarser sand finding their way to the stone; the stone is afterwards washed in clean water and dried, and the grain tested with a crayon. If it prove too coarse or too fine, or if scratches are discovered, the graining is done over again.

The drawing is then traced upon the stone. As it has to be reversed, the tracing is fastened face downwards, red tracing paper is introduced between, and the outline carefully gone over with a steel tracing point or a hard pencil. The tracing papers are then removed, and the surface of the stone protected with a sheet of plain paper. The hand-board is placed across to keep the warmth of the hand from causing the condensation of moisture resulting from its coming in contact with the paper covering the stone. The paper covering the part of the drawing to be first commenced is then removed. The crayons are pointed with the knife, cutting from the point upwards.

Great care and cleanliness are necessary to prevent injury to the work. If the artist wishes to talk he ought first to cover up the surface of the stone, as a drop of saliva falling upon it prevents the penetration of the chemical chalk, and a white spot will be the result when the drawing is "brought up" by the printer. If the stone is touched by greasy hands, the form of the fingers and of the skin will appear in black.

The drawing is commenced by outlining. For this purpose the hardest chalk (copal) may be used, but No. 1, when it will answer the purpose, is better. The "tinting" or shading follows; lights may be picked out with the scraper or penknife, and ink used when sharp, dark touches are desirable. It is difficult to rectify mistakes;—prevention is better than cure. In reversing the drawing a small hand looking-glass will be found useful.

When completed the drawing is "etched." There are two different ways of applying the acid—one by flooding the stone with nitric acid diluted with water, the other with acid diluted with gum-water, applied with a flat, soft brush about 4 or 5 inches in width. Although this operation appears simple, it is not without risks; much of the success of the impressions depends upon it. If the stone is too strongly etched, the delicate tints and lines disappear; if not etched strong enough, the drawing is apt to lose clearness, and run smutty in printing. When the etching is completed, the water is drained off and the stone gummed and allowed to dry. It may then be put into the hands of the printer for proving.

Pen and Brush Method.—The surface of the stone is ground and afterwards polished with Water-of-Ayr stone or snake-stone. The drawing or writing is traced upon the surface in the manner already described. The principal drawback in this method is the necessity of reversing writing and lettering, which cannot be done without considerable practice. Its advantages over the transfer method scarcely compensate for the additional difficulties. The stone is etched as in chalk drawing before passing into the printer's hands.

Engraving on stone is chiefly useful in the reproduction of drawings by architects, civil engineers, &c. Its advantages are accuracy and sharpness in drawing and printing. A thin film of gum is spread on the surface of the stone, and when dry washed off; a dark ground is then laid on by rubbing in Paris black. Red grounds also are sometimes

used. The tracing, if on a black ground, is made with paper prepared with chrome yellow, if on a red ground with Paris black. The method of engraving is simple. The tools are strong needles, firmly fixed in cane handles, and good spring dividers; the incised lines show white upon the black or red ground. When the work is finished they are filled up with fatty ink, and the stone cleared with water and a piece of coarse flannel.

In printing, the stone is damped in the usual way, but the ink is applied with a dabber instead of a roller.

Lithography on Paper, or Transfer Lithography.—By this method the work is done on paper, and afterwards transferred to the stone. The paper has been already described, as also the instruments used in writing and drawing. The ink is prepared by rubbing a small quantity into a saucer of white delft or china, the saucer being first heated to make the ink adhere; water is then added, and the ink rubbed with the finger till it dissolves. Care has to be taken to make it of the proper consistency. If pale and thin, it will not transfer properly; if too thick, it will not flow freely from the pen or brush, and will spread in transferring.

The paper should not be handled or touched, except at the edges. Finger marks from a moist or greasy hand will roll-up black. A piece of clean white paper is kept under the hand when working. The same line must not be gone over twice while wet, as the composition on the surface of the paper is apt to get mixed with the ink and destroy its qualities. In drawing on chalk transfer paper the crayon is used instead of the brush or pen. Dark touches may be put in with ink, and the lights picked out with the knife.

The stone for the reception of transfers is polished free from perceptible scratches, and is generally warmed to make it more susceptible of receiving the ink. The transfer is placed face downwards on the stone, pulled repeatedly through the press, and afterwards removed to the trough, where hot water is poured over it. It is then peeled off, leaving the ink and the composition on the stone; the latter is washed off, and the stone gummed and allowed to dry. The work is afterwards "proved" by rolling-up, cleaning, etching, and taking the first impressions.

The transfer method is also applied successfully to the reproduction by lithography of engraved plates, wood engravings, and type.

Photo-Lithography.—By this method copies of prints or drawings executed in clear lines or dots can be produced. They may be either of the same or of altered dimensions. The copying is done by photography upon glass; but, as it is necessary that the negatives should have straight marginal lines, ordinary photographic lenses are not adapted for the purpose—"rectilinear," "aplanatic," "symmetrical," and other varieties being used instead. The negative is put into a photographic printing frame, and a piece of sensitive transfer paper placed face downwards upon it, the glass side being exposed to the light. The time of exposure varies according to the intensity of the light and the quality of the negative. When sufficiently exposed it is carried into a dark room, the photographic print taken out of the frame, laid face downwards on a stone coated over with transfer ink, and pulled through the press. It is then soaked for a few minutes in water warmed to the temperature of 100°, and the inked side of the paper carefully sponged with gum-water to remove the transferring ink from the parts upon which the light could not act. After being washed in warm water it is allowed to dry, and is then transferred to the stone and printed from in the usual manner.

Zincography so nearly resembles lithography in its principles that a very few words of explanation will be sufficient. Zinc plates possess the advantage of costing less

and being much more portable than lithographic stones, and are easily cut into convenient sizes. They are grained in the same manner as lithographic stones, a muller of zinc being used instead of one of stone. Drawings on zinc, whether in chalk or ink, are executed on a grained surface. Zinc plates are subject to oxidation, and care must be taken to dry them off quickly after graining. The drawing is done precisely in the same way as on stone; the etching solution is applied with a fat camel-hair brush. It consists of a decoction of nut-galls; a solution of gum and phosphoric acid is sometimes added. During printing the plate is screwed for support to a block of beech or other hard wood. As neither crayon nor ink penetrates the zinc as they do the stone, the adhesion of the ink forming the drawing is less thorough than in lithography, and greater precautions have to be taken to prevent accidents in printing.

Chromo-Lithography—Great advances have been made in recent years in this branch of the art, notably in the reproduction of works of an artistic character. Its simplest form is the tint, in several gradations of one colour, printed over drawings in chalk or line; in its more elaborate forms it includes imitations of water-colour drawings, decorative and ornamental designs, &c. The term "chromo-lithography" is usually applied only to the more elaborate kinds of colour printing.

All lithographs in two or more colours are printed from two or more stones. It is therefore necessary to employ some method to get a correct repetition of the subject on the first stone made upon the others, and to be able in printing to place the sheet so correctly in position that the second and each succeeding printing shall fall exactly into its place upon the first. Much of the success of the work depends upon this, and various modes of "registering," by "lay," by needles, by fixed points, &c., are employed. The first drawing is generally in outline. It is called the *keystone*, and provision is made in it for "registering," according to the particular method adopted by the artist. It is used only to take as many impressions on other stones as are required for the several colours, and as a means of getting each colour in its exact place. In work of an artistic character it is omitted in printing.

For ordinary colour printing the stone is polished; when gradation of colour is required the stone is grained, but in a somewhat coarser way than for chalk drawing. It will be sufficient here to describe the production of drawings with two tints. The principal drawing is done upon a grained stone in chalk, and should be very bold, more like a sketch on tinted paper, the middle and finer tints being left out. The stone is then etched, and two impressions are taken, so that when each of these is put upon a roughly-grained stone, and passed through the press, counter impressions will be found upon the stones, revealing the drawing quite distinctly. After having cut in the outlines with a sharp-pointed graver, or steel needle, the artist covers those parts on the two stones which are not to appear in the one or the other colour, as well as the margin of the two stones, with a brush containing acid and gum. The stones are then warmed, and a composition containing the same ingredients, as soft chalk, with double the quantity of soap, and three times the quantity of tallow, is rubbed over it with a bit of coarse flannel, until it is of a dark greyish-brown colour. From having been previously cut in, the outline comes out very distinctly. The artist can now produce an effect similar to crayon sketches which have been washed in with two separate colours. Those portions which have been rubbed in, and which appear dark greyish-brown, form the middle tint, and the scraper may be used to reduce the colour of the tint where the gradation of colour is desired,—the darkest portions being laid in with lithographic ink,

and the blending together done with chalk, brush, pen, and scraper, so as to produce in many places the effect of shadings of one colour over another. When the work is of a very elaborate or complicated nature, the order in which the colours should succeed each other in printing is of much importance, and requires to be very carefully considered. In highly finished chromo-lithographs, fifteen or more printings are frequently necessary. Difficulties sometimes arise from the paper stretching, either from the moisture on the surface of the stone or from the action of the press.

Lithography differs from chromo-lithography only in name, and is a mere vulgar attempt to imitate oil painting. The finished print is mounted on canvas, sized, and varnished. The loaded colours and rough textures, if there happen to be such in the original, are suggested by embossing, with what result it is hardly needful to say.

Instrument, Tools, and Apparatus used in Printing—Lithographic presses are of a great variety of construction, and we can only glance at the chief points in their mechanism. The scraper is a wedge-shaped plate of boxwood, fixed to the bottom of the platen; its edge is covered with a piece of leather, and properly adjusted. The table on which the stone with the paper for receiving the impression is placed, and on which the tympan is brought down, is by means of a handle or wheel, brought upon the metallic moving roller and under the scraper; the pressure is applied with a lever, and continued from one end of the stone to the other; when it has passed through the press, the lever is lifted, the moving table brought to its original place, and the printed sheet removed. The lithographic steam-press began to be generally used about 1837, and has quite revolutionized the lithographic trade.

The rollers for printing may be made of different lengths, from 6 to 24 inches long, and 5 to 5 inches in diameter. They are made of wood of the alder and lime tree, with wooden handles to project and hold by, the roller is then covered with several complete turns of flannel, well stretched and fastened by sewing at the extremities near the handles; the whole is then covered with oil-skin, sewed with great care, so as to fit tightly, and laced near the handles. For printing chalk, tints, and colours, skins of different preparations are required. Hollow metal rollers covered with oil-skin and oil-skin, are in use on some parts of the Continent, where they are preferred to rollers made of wood.

The best varnishes for making the printing-ink are boiled from old linseed oil, of different degrees of strength—thin, middle, strong, and very strong varnish, for printing with gold-leaf, bronze, and dusting colours, the very strongest varnish is required. For writings, maps, and music, common calcined lamp-black is ground with the varnish; some hard body is added to improve the colour, and to make the ink dry in a short time; for chalk ink, Paris black is used instead of the common lamp-black. For tinting and colour-printing, colourless or bleached varnish must be used, as otherwise the purity of the colours will suffer.

Printing—After the stones containing the writings or drawings in chalk and those used for tinting or colour-printing are etched, and the preparation has become dry, the stones may be put into the press and properly fixed. To prevent a stone containing drawings of any value from breaking, it should, if thin, be backed to another stone, or, what is better, to a slab of Aberdeen granite. This is done by a mixture of plaster of Paris and cold water, of the consistency of syrup, a pretty thick coating of which should be spread evenly and quickly on the slab; the stone containing the drawing is placed into this layer, and moved in all directions until the plaster of Paris becomes quite hard, which will take place in a very short time. After the printing is accomplished, the stone can be quite easily removed from the slab, by using a chisel, and by giving some side strokes with a wooden hammer. The old dry plaster of Paris is now removed, and the slab is again fit for use.

Everything being ready, the gum is quickly washed away with a soft Turkey sponge and water; the writing or drawing is then obliterated by taking a clean sponge and oil of turpentine, to which may be added, at pleasure, a few drops of sweet oil, after which the stone must be cleaned with water. An entirely clean sponge (or for stones made of soft canvas manufactured for the purpose) is now required for the printing. The stone is slightly wetted with this sponge; the printing roller, charged already with the proper ink, is passed repeatedly over the whole stone, and the writing or drawing will begin to reappear; the roller is again worked on the ink-slab, the stone wetted away with the sponge, and again rolled over, until the writing or drawing appears in full strength. A sheet of damped paper (dry paper may be used for writings and drawings in line) is put on the stone, the tympan is let down, the scraper brought to its proper place, the pressure effected, and, by means of the handle, cross, or wheel, according to the style of press, the table with the stone is slowly and equally drawn through to nearly

the end of the stone, for which purpose the press requires to be set properly beforehand. The printer now releases the pressure, the table with the stone runs to its original place, the tympan is put back, and the impression is carefully taken up from the stone. The stone is then again wetted as before, inked in anew, the paper placed upon the stone, and further impressions are effected. When the stone is to be kept after the required number of impressions has been struck off, it should always be inked up with preserving ink, which is made by melting lard, tallow, and wax, in equal proportions, with a quantity of printing-ink. When about to be used, this preserving-ink may be thinned with some oil of turpentine, thinly spread on a roller kept for this purpose; it must then be properly run on the slab, the writing or drawing is washed out with oil of turpentine, the whole removed with a clean sponge, and the stone wetted and inked in with this preserving-ink. A few minutes afterwards, when the turpentine has evaporated, a thin solution of gum-arabic is spread over the stone, containing a little sugar-candy to prevent the cracking of the gum by change of atmosphere. The stone will keep any length of time; but the preserving-ink should be renewed at least every twelve months.

The printing of tint and colour stones is treated in the same way, only the rollers, varnishes, and colours are different from those used for ordinary black and chalk printing. The printing of the class of work requires great skill and taste. Many of the lithographic printers of London, Paris, Brussels, Munich, Berlin, Vienna, and Dresden are justly famed for their beautiful productions.

An engraved stone is printed by using a small wooden tapper or tampon, either round at the sides, flat below, with handle at top, or square, with the corners rounded off. This tampon is cornered several times with a very coarse blanket, or coarse thick firm cloth, fastened at the sides, the ink is then spread very thinly on the slab, the tapper is properly tapped into it, the gum is removed from the stone, and the drawing is removed with oil of turpentine, the stone is wetted, the tampon is tapped over the whole drawing, the stone cleaned with a lot of wet canvas, and finally a printing roller is passed once or twice over the stone, which removes all impurities, a damp sheet of paper is then placed on the stone, and the impression made as formerly explained.

Some printers print drawings, pictures, or drawings done with thin lines entirely with the roller, which is a great saving of time, other printers begin an engraving with a large shoe brush with long stiff bristles—which is rubbed on the ink-slab to give it the ink required—by brushing over the drawing in all directions.

Paper.—The proper selection of paper for lithographic printing when beauty of impression is a chief consideration, is of great importance. Hand-made and hand-sized papers are objectionable, the materials used in making being frequently inimical to perfect lithographic printing. Absorbent papers, such as India paper, plate-paper, half-sized plate-paper, and fine printing paper yield the best impressions, common writing papers, hand-made writing, loan, or other hand-made English-sized papers should be used only when the work is for business or similar purpose.

Since the invention of photography, and its wide application to processes connected with art, artistic lithography, except in the way of colour printing, has been perhaps rather less in demand than formerly. Many of the finest British examples of lithographic art date from more than twenty to thirty years back, when artists such as J. D. Harding, Samuel Prout, Louis Haghe, Ghamer, William Simpson, and others were largely—some of them almost exclusively—engaged in its practice. Harding, although practising as a water-colour painter, devoted much of his time to lithography. The dexterity and brilliancy of his execution give to his works in this style a peculiar charm, altogether wanting in the more laboured productions of the professional lithographic artist. Of this quality in Harding's drawings on stone, Mr Ruskin writes—"His execution, in the way, no one can at all equal. The best chalk drawing of Calame and other foreign masters is quite childish and feeble in comparison." Samuel Prout, also a water-colour painter, produced many admirable works in lithography. Mr Ruskin's testimony may again be quoted—"All his published lithographic sketches are of the greatest value, wholly unrivalled in power of composition, and in love and feeling of architectural subject." "His lithographic work (*Sketches in Flanders and Germany*), which was, I believe, the first of the kind, still remains the most valuable of all, numerous and elaborate as its various successors have been. Their value is much increased by the circumstance of their being drawn by the

artist's own hand upon the stone." Louis Haghe's work on the *Architecture of the Middle Ages in Germany and the Netherlands*, Roberts's *Holy Land and Egypt* (drawn on stone by Haghe), and Simpson's drawings of the Crimean war may also be cited as excellent examples of artistic lithography. Lithographic studies of heads and figures by Julien of Paris, and other foreign artists, were at one time largely employed as copies by drawing masters, the new system of teaching introduced of late years has almost put an end to their use for this purpose, and they are now less frequently met with. Although lithography is increasingly employed for commercial and other purposes, artists of first-rate ability now seem, on the whole, to prefer other processes for the reproduction of their works. (G 22)

LITHUANIANS, a people (about 3,000,000 in number) of Indo-European origin, which inhabits several western provinces of Russia and the north-eastern parts of Poland and Prussia, on the shores of the Baltic Sea, and in the basins of the Niemen and of the Duna. Very little is known about their origin, and nothing about the time of their appearance in the country they now inhabit. Ptolemy mentions (lib. iii. chap. 5) two clans, the Galindæ and Sudeti, most probably Lithuanians of the western branch of this nationality, the Borussia. In the 10th century they were already known under the name of Litvæ, and together with two other branches of the same stem,—the Borussia and the Lettæ,—they occupied the south-eastern coast of the Baltic Sea from the Vistula to the Duna, extending north-east towards the Lakes Wierzy-järvi and Peipus, south-east to the watershed between the affluents of the Baltic and those of the Black Sea, and south to the middle course of the Vistula (Brest Litovsk),—a tract bounded by Finnish tribes in the north, and by Slavonians elsewhere.

The country which since that time they have continued to inhabit is flat, undulating, and covered by numberless small lakes, ponds, and wide marshes, which, though to a great extent drained during the last ten centuries, nevertheless still cover immense tracts of land. The costly work of artificial draining has been actively carried on during late years, but in the south the marshes are disappearing slowly. The soil, being sandy in the north, and a hard boulder-clay elsewhere, is unproductive. Thick forests cover it, and—though considerable tracts have been destroyed by fire and by the hatchets of the *budniks* who during many centuries have cleared the most remote thickets, founding there their villages, while, later, wide forest regions, given by Catherine II. as gifts to her officials, have quite disappeared—there still remain immense tracts of land covered with nearly virgin forests, thus, the Byelovezh Pushcha covers no less than 650,000 acres of land on the level plateau 660 feet high, where tributaries of the Nareff and Bug have a common origin in marshes. These forests have played an important part in the history of the Lithuanians, giving many original features to their history, as well as to their mythology, poetry, and music. They protected them from foreign invasions, and have contributed to the maintenance of their national character, notwithstanding the vicissitudes of their history, and of their primitive religion until the 14th century. Their chief priest, the Krive-Krivyto (the judge of the judges), under whom were no less than seventeen different classes of priests and elders, worshipped in the forests; the Waidelots brought their offerings to the divinities at the foot of mighty oaks, and even during the 14th century an unextinguishable fire, the "zinc," was maintained in the midst of the "pushcha," or "pushcha"; even now, the worship of great oaks is a widely spread custom in the villages of the Lithuanians, and even of the Lettæ. In the absence of great forests they worship isolated trees.

Even at that time the Lithuanian stem was divided into three main branches—"the *Borussians* or *Prussians*"; the *Lets* (who call themselves *Latvis*, whilst the name under which they are known in Russian chronicles, *Letygola*, is an abbreviation of *Latvin-galas*, "the confines of Lithuania"), and the *Lithuanians*, or rather *Lituanians*, *Litoi*, or *Letuvivinkai*,—these last being subdivided into Lithuanians proper, and *Jmud* (*Zmuds*, *Samogitians*, or *Zemales*), the "Lowlanders." To these three main branches, which have maintained their national distinctions uninterrupted until the present time, must be added also the *Yatvays*, or *Yatvings*, a warlike, black-haired people who inhabited the thick forests at the upper tributaries of the Niemen and Bug, and the survivors of whom are easily distinguishable now as a mixture with White-Russians and Mazurs in some parts of the governments Grodno and Polesk, and in several north-eastern parts of those of Lomza and Warsaw. Nestor's chronicle distinguishes also the *Jemgala*, who later became known under the name of *Semigalia*, and inhabited in the 10th century the left bank of the Duna. Several authors consider also as Lithuanians the *Kors* of Russian chronicles, or *Courons* of Western authors, who inhabited the peninsula of Courland, and the *Galad*, a clan settled on the banks of the Porvta, tributary of the Moskva river, which seems to have been thrown far from the main stem during its migration to the north.¹ The *Krivitschi*, who inhabited what is now the government of Smolensk, whose name recalls the Krive-Krivoyto, and whose ethnological features recall the Lithuanians, seem to belong to the same stem; but now these are rather a mixture of Lithuanians and Slavonians.

All these peoples are only ethnographical subdivisions, and each of them was subdivided in its turn into numerous independent clans and villages, separated from one another by forests and marshes; they had no towns or fortified places, a feature which has struck many earlier Occidental writers. The Lithuanian territory thus lay open to foreign invasions, and the warlike Russian *Kniazes*, as well as the German crusaders, availed themselves of the opportunity. The Borussians soon fell under the dominion of Germans, and ceased to constitute a separate nationality, leaving only their name to the state which later became Prussia. The Lets were driven farther to the north, mixing there with Livs and Ehsts, and fell under the dominion of the Livonian order. Only the Lithuanians proper, together with Samogitians, succeeded in forming an independent state. The early history of this state is but imperfectly known, all the more that the old Lithuanian chronicles have suffered from subsequent alterations (*Antonovich, loc. cit.*). During the continuous petty war carried on against Slavonic invasions, the military chief of one of the clans, Ryngold, acquired, in the first half of the 13th century, a certain preponderance over other clans of Lithuania and Black Russia (*Yatvays*), as well as over the republics of Red Russia. At this time, the invasions of the Livonian order becoming more frequent, and always extending southward, there was a general feeling of the necessity of some organization to resist them, and Ryngold's son, Mendowg, availed himself of this opportunity to pursue the policy of his father. He made different concessions to the order, ceded to it several parts of Lithuania, and even agreed to be baptized, in 1250, at Novogrod Litovskiy, receiving in exchange a crown from Innocent IV., with which he was crowned king of Lithuanians. He ceded also the whole of Lithuania to the order in case he should die without leaving offspring. But he had accepted Christianity only to increase his influence among other clans; and,

as soon as he had consolidated a union between Lithuanians, Samogitians, and Cours, he relapsed, proclaiming, in 1260, a general uprising of the Lithuanian people against the Livonian order. The yoke was shaken off, but internal war followed, and three years later Mendowg was killed. About the end of the 13th century a new dynasty of rulers of Lithuania was founded by Lutouwer, whose second son, Gedymin (1316-1341), with the aid of fresh forces he organized from his relations with Red Russia, established something like regular government; he extended at the same time his dominions over Russian countries—over Black Russia (Novogrodok, Ziditoff, Grodno, Slonim, and Volkovysk) and the principalities of Polotsk, Tournovsk, Pinsk, Vitebsk, and Volhynia. He named himself *Rex Lithovinarum et multorum Ruthenorum*. In 1326 he concluded a treaty with Poland against the Livonian order, which treaty was the first step towards the union of both countries realized two centuries later. The seven sons of Gedymin considered themselves as quite independent; but two of them, Olgerd and Keistut, soon became the more powerful. They represented two different tendencies which existed at that time in Lithuania. Olgerd, whose family relations attracted him towards the south, was the advocate of union with Russia; rather politician than warrior, he increased his influence by diplomacy and by organization. His wife and sons being Christians, he also soon agreed to be baptized in the Greek Church. Keistut represented the revival of the Lithuanian nationality. Continually engaged in wars with Livonia, and remaining true to the national religion, he became the national legendary hero. In 1340 both brothers agreed to re-establish the great principality of Lithuania, and, after having taken Vilna, the old sanctuary of the country, all the brothers recognized the supremacy of Olgerd. His son Yagello, who married the queen of Poland, Yadviga, after having been baptized in the Latin Church, was crowned, on February 14, 1386, king of Poland. At the beginning of the 15th century Lithuania was a mighty state, extending her dominions as far east as Vyazma on the banks of the Moskva river, the present government of Kaluga, and Poutivl, and south-east as far as Poltava, the shores of the Sea of Azoff, and Hadji-bey (Odessa), thus including Kiass and Lontak. The union with Poland remained, however, but nominal until 1569, when Sigismund Augustus was king of Poland. In the 16th century Lithuania did not extend its power so far east and south-east as two centuries before, but it constituted a compact state, including Polotsk, Moghileff, Minsk, Grodno, Kovno, Vilna, Brest, and reaching as far south-east as Tchernigoff. From the union with Poland, the history of Lithuania becomes a part of Poland's history, Lithuanians and White-Russians partaking of the fate of the Polish kingdom. After its three partitions, they fell under the dominion of the Russian empire. In 1793 Russia took the provinces of Moghileff and Polotsk, and in 1795 those of Vilna, Troki, Novogrod-Syeverek, Brest, and Vitebsk. In 1797 all these provinces were united together, constituting the "Lithuanian government" (*Litovskaya Gubernia*). But the name of Lithuanian provinces was usually given only to the governments of Vilna and Kovno, and, though Nicholas I. prohibited the use of this name, it is still used, even in official documents. In Russia, all the White-Russian population of the former Polish Lithuania are mostly considered as Lithuanians, the name of Jmud being restricted to Lithuanians proper.

The ethnographical limits of the Lithuanians are quite undefined, and their number is estimated very differently by different authors. The Lets occupy a part of the Courland peninsula (according to M. Rittich, they numbered there 305,800 in 1870, to which several authors add 188,800 Cours), of Livonia (416,400 at same date), and of Vitebsk (165,900), a few other settlements being spread also in the governments of Kovno (16,500), St. Petersburg (2700), and

¹ W. B. Antonovich, *A Sketch of History of the Great Principality of Lithuania*, and Professor Barczak, *Russian Historical Geography*, both in Russian.

Moghileff (1000). The Lithuanians proper inhabit the governments of Kovno (485,610), Vilna (850,700), Suwalki (54,800), and Grodno (2500), whilst the Samogitians, or Jmud, inhabit the governments of Kovno (498,900) and Suwalki (165,200). To these must be added about 200,000 Bessarabians, the whole number of Lithuanians being 2,687,000 in 1870 (3,878,000 with the Gours), or, taking into account the rate of increase of population for different governments, about 3,014,700 in 1882 (3,281,000 with Gours). Other authors estimate the number of Lithuanians in the Polish provinces at 277,050 in 1860, probably including Yatvyags, mixed to some extent with Mazurs. In this case the number of Lithuanians would be in 1882 about 3,082,000 (3,341,000 with Gours). They are now slowly extending towards the south, especially the Letts, who leave their country in consequence of want of land and of the difficulty they experienced in getting means of subsistence, numerous emigrants have already penetrated into Slavonic lands as far as the government of Voronezh.

The Lithuanians are well built, the face is mostly elongated, the features fine, the very fair hair, blue eyes, and delicate skin distinguish them from Poles and Russians. Their dress is usually plain in comparison with that of Poles, and the predominance in it of greyish colours has been frequently noticed. Their language has great similarities to the Sanskrit. It is affirmed that while Sanskrit phrases are well understood by the peasants of the banks of the Niemen. But it contains also a considerable amount of Slavonic words. The vocabulary is very copious, especially in words referring to natural phenomena, and which express certain pathological states of the mind. Primitives are exceedingly numerous, and various diminutive forms are applied even to adjectives and verbs. But, as a whole, the Lithuanian language is at a very low stage of development, and the written literature is very poor; only religious books, a few translations, and a single newspaper are published in it. On the other hand, the unwritten popular literature is very rich, and contains true treasure of poetry. It was long doubted if Lithuanians have any epic poetry; it now appears, however, that there are, scattered in songs, fragments of a great Lithuanian epic poem. But the popular poetry is especially rich in idyllic and lyric songs, imbued with tender love and melancholy. The songs of nature, and especially the elegies, are remarkable for their absolute chastity, the irony which sometimes appears in them is usually refined and gentle. The elegies (*trauzos*) are very melancholy, and of a rare beauty. The national character is fully expressed in these songs,—not warlike at all, melancholy, very lovely, and very sad.

The language of the Letts is, according to Schleicher, as similar to the Lithuanian as the Italian to the Latin, but contains a greater mixture of German and Slavonic words. The literary language is more developed. A scientific Lettish grammar was published by Stender at the end of the last century, and the Letts possess translations of Shakespeare, Schiller, and other great poets. Five political papers were published in Lettish in 1878. A revival of national feeling having begun in this century, rich collections of Lettish songs were published by Germans, Russians, and Letts. M. Eversmann's collection, published by the Moscow Anthropological Society, being the most recent. The Lettish songs have the same characters as those of the Lithuanians, to which a special feature, the hatred of the people to the German landholders, must be added.

The Letts of Courland, with the exception of about 50,000 who belong to the Greek Church, are Lithuanians. Nearly all are now. Those of the government of Vitebsk, who were under Polish dominion, are Catholics, as well as the Lithuanians proper, a part of whom, however, have returned to the Greek Church, in which they were before the union with Poland. The Samogitians are Catholics; they more than other Lithuanians have preserved their national features. But all Lithuanians have retained much of their heathen practices and creed; the names of pagan divinities, very numerous in the former mythology, are continually mentioned in songs, and also in common speech.

The chief occupation of Lithuanians is agriculture. The trades in towns are generally carried on by men of other races, chiefly by Germans, Jews, or Poles. The only exception is afforded to some extent by the Letts. The Samogitians are good hunters, and all Lithuanians are given to apiculture and cattle breeding. But the Lithuanians, as well in the Baltic provinces as in the central ones, were until the last recent years proprietors of almost all they held. They have given a few families to the Russian nobility, but the great mass of the people become serfs of foreign landowners, German and Polish, who reduced them to the greatest misery. Since the Polish insurrection of 1863, the Russian Government has given to the Lithuanians the land of the Polish proprietors on much less terms than in former times, and the allotments of soil and the redemption taxes are very unequally distributed; and a not insignificant number of peasants (the *kolonizatsii*) were even deprived of the land they had for centuries considered their own. The Letts remain in the same state as before, and are restrained from emigrating en masse only by coercive measures. (T. A. K.)

LITMUS (German, *Lackmus*; French, *Tournefort*), a colouring matter which occurs in commerce in the form of small blue tablets, which, however, consist mostly, not of the pigment proper, but of carbonate and sulphate of lime and other matter devoid of tinctorial value. Litmus is never used as a dye, but is extensively employed by chemists as a reagent for the detection of free acids and free alkalis. An aqueous infusion of litmus, when exactly neutralized by an acid, exhibits a violet colour, which by the least trace of free acid is changed to red, while free alkali turns it to blue. The reagent is generally used in the form of test paper,—bibulous paper dyed red, purple, or blue by the respective kind of infusion. Litmus is manufactured in Holland from the same kinds of lichens (species of *Rocella* and *Lecanora*) as are used for the preparation of ARCHIL (q.v.).

What orelin is to erchil, a substance "azolitum," which Kane extracted from it, seems to be to litmus. At any rate, Kane's analysis supports the idea of its being formed from orelin, thus,—

A solution of this substance when treated with nascent hydrogen loses its colour. So does litmus solution when left to itself in closely stoppered bottles. When preserved in contact with air it retains its colour.

LITTLE FALLS, a village and township in Herkimer county, New York, on the Erie canal, 73½ miles west-north-west of Albany by the New York Central and Hudson River Railroad, at a point where the Mohawk river passes by a series of rapids through a picturesque defile. The water-power is turned to account in the manufacture of paper, woollen and cotton goods, starch, &c. The village, which lies partly in the township of Manheim, had a population of 6910 in 1880. Little Falls has the largest cheese market in the United States.

LITTLE ROCK, capital of the State of Arkansas, United States, as well as of Pulaski county, is situated on the south bank of the Arkansas river, about 280 miles from its mouth, and near the centre of the State. It derives its name from occupying the top of a rocky cliff about 50 feet in height, which is much less conspicuous than the precipitous cliffs that line the river just above the city. The river, which is navigable by large steamers to this point during two-thirds of the year, is crossed here by an iron drawbridge on the St Louis, Iron Mountain, and Southern Railway. Little Rock, founded in 1820, contains the State house, the State asylums for the blind and for deaf mutes, the State prison, the State library, St John's Military College, and other schools. It is also the seat of the United States court of the eastern district of Arkansas, and a United States arsenal and land office. Flour-mills, carriage-works, and foundries are among the chief industrial establishments. Population in 1880, 13,138.

LITTLETON, THOMAS DE, of Frankley in Worcestershire, judge of the court of common pleas in the reign of Edward IV., and author of the well-known work on *Twines*. Littleton's surname was that of his mother, who was the sole daughter and heiress of Thomas de Littleton, lord of Frankley. She married on Thomas Westcott. Thomas was the eldest of four sons of the marriage, and took the name of Littleton, or, as it seems to have been more commonly spelt, Lutulton. The date of his birth appears to be uncertain. He is said by Sir E. Coke to have been a member of the Inner Temple, and to have lectured there on the Statute of Westminster II., *De Donis Conditionalibus*. His name occurs in the Paston letters about 1445 as that of a well-known counsel. He appears to have been recorder of Coventry in 1450, to have been made king's sergeant in 1455, and afterwards to have been a justice of assize on the northern circuit. In 1466 he was made a

judge of the common pleas, and in 1475 a knight of the Bath. He died, according to the inscription on his tomb in Worcester cathedral, on August 23, 1481. He married Joan, widow of Sir Philip Chestwind of Ingestre in Staffordshire, and by her had three sons, through whom he became ancestor of the families in which are the existing peerages of Lyttelton and Hatherton.

The work on tenures was probably written late in his life. It is addressed to his second son Richard, who went to the bar, and whose name occurs in the year books of the reign of Henry VII. The book, both historically and from its intrinsic merit, may be characterized as the first textbook upon the English law of property. The law of property in Littleton's time was mainly concerned with rights over land, and it was the law relating to this class of rights which Littleton set himself to digest and classify. The time was ripe for the task. Ever since the Conquest regular courts of justice had been at work administering a law which had grown out of an admixture of Teutonic custom and of Norman feudalism. Under Henry II the courts had been organized, and the practice of keeping regular records of the proceedings had been carefully observed. The centralizing influence of the royal courts and of the justices of assize, working steadily through three centuries, had made the rules governing the law of property uniform throughout the land; local customs were confined within certain prescribed limits, and were only recognized as giving rise to certain well-defined classes of rights, such, for instance, as the security of tenure acquired by villeins by virtue of the custom of the manor, and the rights of freeholders, in some towns, to dispose of their land by will. Thus, by the time of Littleton (Henry VI and Edward IV.), an immense mass of material had been acquired and preserved in the rolls of the various courts. Reports of important cases were published in the "year books." A glance at Statham's *Abreviement*, the earliest digest of decided cases, published nearly at the same time as Littleton's *Tenures*, is sufficient to show the enormous bulk which reported cases had already attained as materials for the knowledge of English law.

Littleton's treatise was written in French, or rather in that peculiar dialect compounded of Norman-French and English phrases called law French. Although it had been provided by a statute of 36 Edward III. that *visu voce* proceedings in court should no longer be conducted in the French tongue, "which was much unknown in the realm," the practice of reporting proceedings in that language, and of using it in legal treatises, lingered till a much later period, and was at length prohibited by a statute passed in the time of the Commonwealth in 1660. Unlike the preceding writers on English law, Glanville, Bracton, and the authors of the treatises known by the names of Britton and Fleta, Littleton borrows nothing from the sources of Roman law or the commentators. He deals purely and exclusively with English law.

The book is written on a definite system, and is the first attempt at something like a scientific classification of rights over land. Littleton's method is to begin with a definition, usually clearly and briefly expressed, of the class of rights with which he is dealing. He then proceeds to illustrate the various characteristics and incidents of the class by stating particular instances, some of which refer to decisions which had actually occurred, but more commonly they are hypothetical cases put by way of illustration of his principles. He occasionally but rarely refers to reported cases. His book is thus much more than a mere digest of judicial decisions, to some extent he pursues the method which gave to Roman law its breadth and consistency of principle. In Roman law this result was attained through the practice of putting to juriconsults hypothetical cases to be solved

by them. Littleton, in like manner, is constantly stating and solving by reference to principles of law cases which may or may not have occurred in actual practice.

In dealing with freehold estates Littleton adopts a classification which has been followed by all writers who have attempted to systematize the English law of land, especially Sir M. Hale and Sir William Blackstone. It is indeed the only possible approach to a scientific arrangement of the intricate "estates in land" known to English law. He classifies estates in land by reference to their duration, or in other words by reference to the differences between the persons who are entitled to succeed upon the death of the person in possession or "tenant." First of all, he describes the characteristics of tenancy in fee simple,—an interest in lands which devolves on the death of the tenant to his heir, whether such heir be of the same line or collateral. Thus it still is as it was in Littleton's time the largest interest in land known to the law. Next in order comes tenancy in fee tail, the outcome, as Littleton informs us, of the Statute of Westminster II, 13 Edw. I. c. 1, "De Donis Conditionalibus," which enacted in the interest of the great lords that a gift to a man and "the heirs of his body" should no longer bear the construction which the courts had put upon the words, holding the donee to be thereby invested with full power over the land so soon as he had issue born, but should descend according to the form of the gift to lineal descendants so long as lineal descendants should exist. The various classes of estates tail are sketched by Littleton with brevity and accuracy, but he is silent as to the important practice, which first received judicial recognition shortly before his death, of "suffering a recovery," whereby through a series of judicial fictions a tenant in tail was enabled to convert his estate tail into a fee simple, thus acquiring full power of alienation. After discussing in their logical order other freehold interests in land, he passes to interests in land called by later writers interests less than freehold, namely, tenancies for terms of years and tenancies at will. With the exception of tenancy from year to year, now so familiar to us, but which was a judicial creation of a date later than the time of Littleton, the first book is a complete statement of the principles of the common law, as they then stood, as to the acquisition, governing and regulating interests in land. The first book concludes with a very interesting chapter on copyhold tenures, which marks the exact point at which the tenant by copy of court roll, the ancestor of the villen, who in his turn represented the freeman reduced to villenage by the growth of the manorial system, acquired security of tenure by the judicial view of the fact that the "will of the lord" was controlled by and could only be exercised in accordance with the "custom of the manor."

The second book relates to the reciprocal rights and duties of lord and tenant, and is mainly of historical interest to the modern lawyer. It contains a complete statement of the law as it stood in Littleton's time relating to homage, fealty, and service, the money compensation to be paid to the lord in lieu of military service to be rendered to the king, a peculiar characteristic of English as distinguished from Continental feudalism.

Littleton then proceeds to notice the important features of tenure by knight's service with its distinguishing incidents of the right of wardship of the lands and person of the infant heir or heiress, and the right of disposing of the ward in marriage. The non-military freehold tenures are next dealt with, we have an account of "service tenure," into which all military tenures were subsequently commuted by a now unrecalled Act of the Long Parliament in 1650, afterwards re-enacted by the well-known statute of 12 Charles II. c. 24, and of "frankalmoin," or the spiritual tenure by which churchmen held, their duty being "to make orisons, prayers, masses, and other divine services for the souls of their grantor or feoffee, and being bound to no fealty to the lord because that his divine service is better for them before God than any other kind of fealty." In the description of burgage tenure and tenure in villenage, the life of which consists in the validity of ancient customs recognized by law, we recognize survivals of a time before the iron rule of feudalism had moulded the law of land in the interests of the king and the great lords. Finally he deals with the law of rents, discussing the various kinds of rents which may be reserved to the grantor upon a grant of lands and the remedies for recovery of rent, especially the remedy by distress.¹

The third and concluding book of Littleton's treatise deals mainly with the various ways in which rights over land can be acquired and terminated in the case of a single possessor or several possessors. This leads him to discuss the various modes in which several persons may simultaneously have rights over the same land, as parsonages,—daughters who are co-heiresses, or sons in gavelkind;

¹ These two books are stated, in a note to the table at the conclusion of the work, to have been made for the better understanding of certain chapters of the *Antient Book of Tenures*. This refers to a tract called *The Old Tenures*, said to have been written in the reign of Edward III. By way of distinguishing it from this work, Littleton's book is called in all the early editions "*Tenures Novellæ*."

joint tenants, where the interest does not pass to the heir of the deceased joint tenant, but devolves upon the surviving joint tenant; and tenants in common, where the interest is separate and descends to the heir of each of the co-tenants, though the land over which the right exists is undivided and held in common with one or more other persons. Next follow elaborate discussions upon what are called estates upon condition,—a class of interests which occupied a large space in the early common law, giving rise on one side to estates tail, on another to mortgages. In Littleton's time a mortgage, which he carefully describes, was merely a conveyance of land by the tenant to the mortgagee, with a condition that, if he repaid to the mortgagee a certain sum on a certain day, he might re-enter and have the land again. If the condition was not fulfilled, the interest of the mortgagee became absolute, and Littleton gives no indication of any modification of this strict rule, such as was introduced by courts of equity, permitting the debtor to redeem his land by payment of all that was due to the mortgagee although the day of payment had passed, and his interest had become at law indefeasible. The remainder of the work is occupied with an exposition of a miscellaneous class of modes of acquiring rights of property, the analysis of which would occupy too large a space.

The work is thus a complete summary of the common law as it stood at the time. It is nearly silent as to the remarkable class of rights which had already assumed vast practical importance—equitable interests in lands. These are only noticed incidentally in the chapter on "Release." But it was already clear in Littleton's time that this class of rights would become the most important of all. Littleton's own will, which has been preserved, may be adduced in proof of this assertion. Although nothing was more opposed to the spirit of Norman feudalism than that a tenant of lands should dispose of them by will, we find Littleton directing by his will the feeble of certain manors to make estates by the persons named in his will. In other words, matter to acquire over lands powers unknown to the common law, the lands had been conveyed to "feoffees" who had full right over them according to the common law, but who were under a conscientious obligation to execute those rights in the direction of the executor of the will of the person whose "use" the lands were held. This conscientious obligation was recognized and enforced by the chancellor, and thus arose the class of equitable interests in lands. Littleton is the first writer on English law after these rights had risen into a prominent position, and it is curious to find in what he says they are ignored by law. Unlike their treatment in the old instruments, the common lawyers wholly refused to recognize the right of the real or beneficial owner, when the legal interest was vested in another, though the latter had then but the semblance without the reality of ownership. Hence it was that the most important class of rights developed outside the common law. After his every attempt to reunite the classes of legal and equitable interests by the Statute of Uses (27 Henry VIII. c. 10), the effect of which was to introduce still greater technicality and complication into the law of real property, the two classes have continued to exist side by side, until in our own times the Judicature Act of 1873, by uniting in one court the tribunals the difference between which originally gave rise to the distinction between legal and equitable interests, has perhaps paved the way for a simpler and more rational classification of rights over land.

The work of Littleton occupies a place in the history of typography as well as of law. The earliest printed edition seems to be that by John Letou and William de Machinle, two printers who probably came from the Continent and carried out their business in partnership, as their note to the edition of Littleton states, "In civitate Londinensi, fecit et perperit per nos Joh. Letou et Will. de Machinle, anno domini 1483." The date is uncertain. The date of the first edition is most probably conjecture, based on typographical grounds, places it about the latter part of 1483. The next edition is one by Machinle alone, and is dated 1484. It is the first time the form *machinle* was then in use; hence also "*Justa possem quo vulgo dicitur Fleta bridge*." Next came the Robert or Broom edition, erroneously said for Sir S. Coke to be the earliest, and to have been printed about 1580. It was, however, of a much earlier date. Tomlins, the latest editor of Littleton, gives reasons for thinking that it cannot have been printed later than 1550, and in a note has been printed at Broom by William W. Taylor at Institution Richard Fyson. Copies of all these editions are in the British Museum. In all these editions the work is styled *Tractatus de personis*, probably a corruption from the "Old Tenures."

There are three early MSS. of Littleton in the University Library at Cambridge. One of these formerly contained a note on the first page, in which it was stated that it was bought in St. Paul's Churchyard on July 20, 1480. It was therefore in circulation in Littleton's lifetime. The other two MSS. are of somewhat later date, but of them certain that some of them may be the earliest English translation of the *Tractatus*, and is probably not later than 1500.

In the 16th century followed in rapid succession from the press of Pynson, Kessellene, Berthelet, Trevel, and others. The practice of annotating the text caused several editions to be introduced, which, however, are easily detected by comparison of the earlier copies. In 1681 West divided the text into seven hundred and forty-six sections, which have ever since been preserved. Many of these editions were printed at the expense of the purpose of the university, and some of them may be seen in Lincoln's Inn Library.

The practice of annotating Littleton was very general, and was adopted by many eminent lawyers, besides the university. The most famous of these was the commentary of this kind, by an unknown hand of earlier date than Sir S. Coke's, was edited by Cary in 1684. Following the general practice of dealing with Littleton as the great authority in the law of England, the most perfect and valuable work that ever was written in any human language, Sir S. Coke makes it the text of that portion of his work which he calls the first part of the Institutes of the law of England, the other parts, the law of property.

The first printed English translation of Littleton was by Rastell, who seems to

have combined the professions of author, printer, and sergeant-at-law, between 1514 and 1539. Many English editions by various editors followed, the best of which is Tolly in 1656. Sir S. Coke adopted some translation earlier than this, which he drew from by the name of Sir S. Coke's translation, &c. However, thorough comments not on the translation but on the French text, and the reputation of the commentary has to some extent overtaken and obscured the intrinsic merit of the original. (See *Ch. D.*)

LITTRE, PAUL MAXIMILIEN ÉMILE (1801-1881), the compiler of the best dictionary of any living language, and the Frenchman of most encyclopedic knowledge and Didot, was born at Paris on February 1, 1801. His father had been a gunner, and afterwards sergeant-major of marine artillery, in the French navy, and was deeply imbued with the revolutionary ideas of the day. Settling down as a collector of taxes, he married Sophie Johannet, a free-thinker like himself, and devoted himself to the education of his son Émile. The boy was sent to the Lycée Louis-le-Grand, where he had for friends Haechette and Eugène Burnouf, and he distinguished himself alike in his work and in his athletic exercises. He had completed his course at school, he hesitated for a time as to what profession he should adopt, and meanwhile made himself master, not only of the English and German languages, but of the classical and Sanskrit literature and philology. At last he determined to study medicine, and in 1822 entered his name as a student of medicine. He passed all his examinations in due course, and had only his thesis to prepare in order to obtain his degree as doctor when in 1827 his father died, leaving his mother absolutely without resources. He at once renounced his degree, and, while attending the lectures of Bayle and taking a keen interest in medicine, began teaching Latin and Greek for a livelihood. He carried a basket on the popular side of the revolution of February 1830, and was one of the national guards who followed Charles X. to Rambouillet. At last, in 1831, when quite thirty years of age, he obtained an appointment as Assistant Curator, the editor of the *National*, who gave him the task of reading the English and German papers for excerpts. Carrel by the merest chance in 1835 discovered the ability of his reader, who from that time became a constant contributor, and eventually director of the paper. In 1836 he began to contribute articles on all sorts of subjects to the *Revue des Deux Mondes*; in 1837 he married, and in 1839 appeared the first volume of his edition of the works of Hippocrates. This volume at once placed Littré in the forefront of the literary and scientific world; its ability was recognized by his election the same year into the Académie des Inscriptions at Belles-Lettres. At the age of thirty-eight then he had won for himself a high reputation as a learned man of letters and of science, but was still tormented by the unsettled ideas and thoughts which generally beset younger men, and were only increased by the study of his favorite authors Byron and Obermann.

At this epoch he came across the works of Auguste Comte, the reading of which formed, as he himself said, "the cardinal point of his life," and from this time onward appears the influence of positivism on his own life, and, what is of even more importance, his influence on positivism; for he gave at least as much to positivism as he received from it. He brought to it a wide knowledge of science and literature, a great and growing reputation, and a clear head. He soon became an intimate friend of Comte's, and set to work to popularize his ideas in numerous works on the positivist philosophy, while at the same time continuing his edition of Hippocrates, which was not completed till 1869, publishing a similar edition of Pliny's *Natural History*, containing sixteen volumes in the place of Faurlat at the commission engaged on the *Histoire littéraire de la France*, where his knowledge of the early French language and literature was invaluable, and contributing largely to the *National* and *Revue des Deux Mondes*. In the revolution

of July 1848 he took a keen interest, and himself took part in the repression of the extreme republican party in June 1849, under the banner of order. His essays, contributed during this period to the *National*, were collected together and published under the title of *Conservation, Révolution, et Positivisme* in 1852, and show, not only a lively faith in a good time coming, but a thorough acceptance of all the doctrines propounded by Comte. However, during the later years of his master's life, he began to perceive that he could not wholly accept all the dogmas or the more mystic ideas of his friend and master, but he studiously concealed his differences of opinion almost from himself, and Comte failed to perceive that his pupil had outgrown him, as he himself had outgrown his master Saint-Simon. Comte's death in 1858 freed Littré from any fear of embittering his master's later years, and he published his own ideas in his *Paroles de la Philosophie Positive* in 1859, and at still greater length in his work in *Auguste Comte et la Philosophie positive* in 1863. In this book he traces the origin of Comte's ideas through Turgot, Kant, and Saint-Simon, then eulogizes Comte's own life, his method of philosophy, his great services to the cause, and the effect of his works, and finally proceeds to show where he himself differs from him. He approved wholly of Comte's philosophy, his great laws of society, and his philosophical method, which indeed he defended warmly against J. S. Mill, but declared that, while he believed in a positivist philosophy, he did not believe in a religion of humanity. In the year 1863, after completing his *Hippocrates* and his *Pliny*, he set to work on his great French dictionary, bringing to the task an unexampled knowledge of old French, of modern and classical languages, and of modern philology, which were to make his dictionary unique in its interest and accuracy. In the same year he was proposed for the Académie Française, but rejected, owing to the opposition of the fiery bishop of Orleans, who denounced him as the chief of the French materialists. He also at this time started with M. Wyzouff the *Philosophie Positive*, a review which was to embody the views of modern positivists, and to which he largely contributed. His life was thus absorbed in literary work, and flowed quietly on, till the overthrow of the empire called on him to take a part in politics. He felt himself too old to undergo the privations of the siege of Paris, and retired with his family to Brittany, whence he was summoned by M. Gambetta to Bordeaux, to lecture on history, and thence to Versailles to take his seat in the senate to which he had been chosen by the department of the Seine. In December 1871 he was elected a member of the Académie Française in spite of the renewed opposition of the Mgr. Dupanloup, bishop of Orleans, who resigned his seat rather than receive him. His dictionary was completed in 1873, and he lived on full of years and honours, for in 1874 he was elected a life senator. The most notable of his productions in these latter years were his political papers attacking and unravelling the confederacy of the Orleanists and legitimists, and in favour of the republic, his republication of many of his old articles and books, among others the *Conservation, Révolution, et Positivisme* of 1852 (which he reprinted word for word, appending a formal, categorical renunciation of many of the Comtist doctrines therein contained), and a little tract *Pour la dernière fois*, in which he maintained his unalterable belief in materialism. When it became obvious that the old man could not live much longer, his wife and daughter, who had always been fervent Catholics, strove to convert him to their religion. He had long interviews with Père Millériot, a celebrated controversialist, and was much grieved at his death; but it is hardly probable he would have ever been really converted. Nevertheless, when on the point of death, his wife had him

baptized, and his funeral was conducted with the rites of the Catholic Church. He died June 3, 1881.

It is almost impossible to characterize the varied learning and immense intellectual activity of Littré. As a philosopher he had popularized and sifted the ideas of Comte, and had succeeded Comte as Comte succeeded Turgot, Kant, and Saint-Simon; as a lexicographer he has been compared to Johnson, though his work is as far ahead of Johnson's as the philological knowledge of the 19th century is in advance of that of the 18th, and as a man of almost universal knowledge, and a writer on every sort of subject, from barbarian learning and modern science to epic poetry and the military genius of Napoleon, he remains unrivalled, even in a country which can boast of Diderot and Comte.

It would take too much space to give a complete list of all Littré's voluminous works, but the following are those of greatest importance:—his editions of Hippocrates, 1839-61, and of *Pliny's Natural History*, 1848-50, his translation of Strabo's *Vie de Jésus*, 1839-40, and Muller's *Manuel de Physiologie*, 1861, his edition of the works of Armand Carrel, with notes, 1864-68; his *Histoire de la langue française*, a collection of magazine articles, 1863; and his *Dictionnaire de la langue française*, 1869-73. In the domain of science must be noted his edition, with Charles Robin, of Nyssen's *Dictionnaire de médecine, de chirurgie, &c.*, 1855, in that of philosophy, his *Analyses et éléments du cours de philosophie positive de M. A. Comte*, 1848, *Applications de la Philosophie positive au Gouvernement*, 1849, *Conservation, Révolution, et Positivisme*, 1852 (2d edition with supplement, 1879), *Paroles de la Philosophie positive*, 1859; *Auguste Comte et la Philosophie positive*, 1863; *La Science au point de vue philosophique*, 1873; *Fragment de philosophie et de sociologie contemporaines*, 1876; and his most interesting miscellaneous works, his *Éléments d'Histoire*, 1850, *La Vieillesse sur la mort d'Alexandre le Grand*, 1865; *Études sur les barbares et le moyen âge*, 1867, *Mémoires d'Éléments*, 1871; *Littérature et Histoire*, 1876; and *Discours de réception à l'Académie Française*, 1878.

For his life consult Sainte-Beuve's notice, 1862, and the numerous articles published after his death in the newspapers and reviews, of which the best are the notices of M. Duval-Gérville in the *Nouvelles Revues* of August 1881, of M. Caro in the *Revue des Deux Mondes*, and of M. Frédéric Godfrey in the *Revue chrétienne* (H. M. S.)

LITURGY. The word "Liturgy" technically denotes the "Order for the Celebration and Administration of the Eucharist." It has come to be used in a more popular sense to denote any or all of the various services of the Christian church, whether contained in separate volumes or bound up together in the form of a Book of Common Prayer. We propose to treat of "the Liturgy" chiefly, but not exclusively, in the former and stricter sense, and, without further discussion of the use of the word in Biblical or patristic literature, and without entering into various questions with reference to their origin, growth, first commit to writing, &c., to give our readers some account of the principal liturgies which exist, or have existed, in the Christian church.

There are five main families or groups of liturgies, three of them Eastern in origin and use, one Eastern in origin but Western in use, one Western both in origin and use. They are known either by the names of the apostles with whom they are traditionally connected, or by the names of the countries or cities in which they are known or believed to have been once or always in use.

GROUP I. St James, West Syrian, Jerusalem.—The principal liturgies to be enumerated under this group are the Clementine, so called from being found in the eighth book of the *Apostolic Constitutions*, which have been erroneously referred to St Clement, first bishop of Rome (lib. viii. 10-16); the Greek and Syrian liturgies of St James; the Greek liturgies of St Basil and St Chrysostom; the Armenian liturgy of St Gregory the Illuminator, first patriarch of Armenia; a large number of later Syrian liturgies springing from the Syrian liturgy of St James. Of these liturgies, that of St Chrysostom is used now by the Orthodox Eastern Church, except on the first five Sundays in Lent, Thursday and Saturday in Holy Week,

the vigils of Christmas and Epiphany, and St Basil's Day, when the liturgy of St Basil is used; and in Lent (except Sundays and Saturdays and Lady Day), when the liturgy of the pre-sanctified is used.

This group, like all the purely Eastern liturgies, is marked by an absence of flexibility as to number and shape of prefaces, collects, &c. Its special feature, if we may adopt a recently employed canon of differentiation, is the position of the great intercession for quick and dead, for rulers in church and state, for the sick, for travellers, for the fruits of the earth, &c., after the consecration of the elements has been completed by the invocation of the Holy Spirit (C. E. Hammond, *Lit. Eastern and Western*, pp. 26-29).

GROUP II. *St Mark, Egyptian, Alexandria*.—This group includes the Greek liturgies of St Mark, St Basil, and St Gregory; the Coptic liturgies of St Cyril, St Basil, and St Gregory; the Ethiopic liturgy known as the "Canon Universalis" or "Liturgy of all the Apostles," together with sixteen other subordinate Ethiopic liturgies. They are distinguished by the position of the great intercession in the middle of the preface, as well as by the prominent part assigned throughout to the deacon.

GROUP III. *St Adeus, East Syrian, Edessa*.—There are three extant liturgies belonging to this group, now exclusively used by Nestorian Christians,—those of SS. Adeus and Maria, Theodore of Mopsuestia, and Nestorius; its titles of three lost liturgies have been preserved,—those of Narses, Barsumas, and Diodorus of Tarsus. The liturgy of the Christians of St Thomas, on the Malabar coast of India, formerly belonged to this group, but it was almost completely assimilated to the Roman liturgy by Portuguese Jesuits at the synod of Diamper in 1599. The characteristic of this group is the position of the great intercession in the middle of the consecration, between the words of institution (or, to speak more accurately, the place where the words of institution must have occurred) and the invocation.

GROUP IV. *St John, Hispano-Gallican, Ephesus*.—This group of Latin liturgies, which once prevailed very widely in western Europe, has been almost universally superseded by the liturgy of the Church of Rome. Where it survives it has been either partially or almost completely assimilated to the Roman pattern. It prevailed once throughout Spain, France, part of northern Italy, and Great Britain and Ireland, in forms of which a detailed account is appended. The term "Ephesine" has been applied to this family of liturgies, chiefly by modern English liturgiologists, to denote a theory as to their origin which, although upheld by other than English writers, must be regarded rather as a possible hypothesis than a proved fact (Leslie, *Pref. to Messar. Missal*, sect. 25, Bickell, *Messe und Pascha*, p. 10). The many traces of Eastern influence in their composition, and the close connexion which is known to have existed at a very early period between the churches of Lyons and of western Asia Minor, have suggested the theory that the latter country must have been the birthplace of this class of liturgies. The names of the apostle St John and of Ephesus his place of residence have been pressed into service as further particularizations of the same theory. The special feature of these liturgies is the position of the great intercession after the offertory, before the commencement of the preface and canon.

The chief traces of Oriental affinity lie in the following points:—(1) the various proclamations made by the deacon, including that of "Silentium facite" before the epistle (Migne, tom. lxxv. p. 534); (2) the presence of a third lesson, preceding the epistle, taken from the Old Testament; (3) the occasional presence of "processes," a series of short intercessions resembling the Greek "Ektenoi," or

deacon's litany; (4) the position of the kiss of peace at an early point in the service, before the canon, instead of the Roman position after consecration; (5) the exclamation "sancta sanctis" occurring in the Mozarabic rite, the counterpart of the Eastern *ta dyia rois dyiois*; (6) traces of the presence of the "Epiclesis," that is to say, the invocation of the Holy Spirit, in its Eastern position, after the words of institution, as in the collect styled the Post-pride in the Mozarabic service for the second Sunday after Epiphany:—"We beseech thee that thou wouldest sanctify this oblation with the permixture of Thy Spirit, and conform it with full transformation into the Body and Blood of our Lord Jesus Christ." On the other hand, the great variability of its parts, and its immense number of proper prefaces, ally it to the Western family of liturgies.

We now proceed to give a more detailed account of the chief liturgies of the Hispano-Gallican group.

1. *The Mozarabic Liturgy*.—This was the national liturgy of the Spanish Church till the close of the 11th century, when the Roman liturgy was forced upon it. Its use, however, lingered on, till in the 16th century Cardinal Ximenes, anxious to prevent its becoming quite obsolete, had its books restored and printed, and founded a college of priests at Toledo to perpetuate its use. It survives now only in that and one other church in Spain, and even there not without certain Roman modifications of its original text and ritual.

Its date and origin, like the date and origin of all existing liturgies, are uncertain, and enveloped in the mists of antiquity. It is evidently not derived from the Roman liturgy. Its whole structure, and every separate detail, disprove such a parentage, and therefore it is strange to find St Isidore of Seville (*Lit. de Eccles. Offic.*, i. 15) attributing it to St Peter. No proof is adduced, and the only value which can be placed upon such an unsupported assertion is that it shows that a very high and even apostolic antiquity was claimed for it. A theory, originating with Pinus, that it may have been brought by the Goths from Constantinople when they invaded Spain, is as improbable as it is unproven. It may have been derived from Gaul. The Gallican liturgy stood to it in the relation of twin-sister, if it could not claim that of mother. The resemblance was so great that, when Charles the Bald (843-877) wished to gain some idea of the character of the already obsolete Gallican rite, he sent to Toledo for some Spanish priests to perform mass according to the Mozarabic rite in his presence. But there is no record of the conversion of Spain by Gallican missionaries. Christianity existed in Spain from the earliest times. Probably St Paul travelled there (Rom. xv. 24-28). It may be at least conjectured that its liturgy was Pauline rather than Petrine or Johannine.

2. *Gallican Liturgy*.—This was the ancient and national liturgy of France till the commencement of the 9th century, when it was suppressed by order of Charlemagne, who directed the Roman missal to be everywhere substituted in its place. All traces of it seemed for some time to have been lost, until three Gallican sacramentaries were discovered and published by Thomasius in 1680, under the titles of *Missale Gallicanum*, *Missale Gallicanum*, and *Missale Francorum*, and a fourth was discovered and published by Mabillon in 1687, under the title of *Sacramentarium Bobbiense*. Fragmentary discoveries have been made since then. More discovered fragments of eleven Gallican masses, and published them at Carlsruhe in 1850. Other fragments from the library of St Gall have been published by Bunsen (*Arch. Aeth. No.*, iii. 263-66), and from the Ambrosian library at Milan by Cardinal Mai (*Script. Vet. Vat. Coll.*, iii. 2, 247). More of this MS. is being prepared for publication by Dr Ceriani. A single page was

discovered in the library of Gonville and Caius College, Cambridge, in 1867, which has not yet been published. These documents, illustrated by early Gallican canons, and by allusions in the writings of Sulpicius Severus, Caesarius of Arles, Gregory of Tours, Germanus of Paris, and other authors, enable scholars to reconstruct the greater part of this liturgy. The previously enumerated signs of Eastern origin and influence are found here as well as in the Mozarabic liturgy, together with certain other more or less minute peculiarities, which would be of interest to professed liturgiologists, but which we must not pause to specify here. They point to the possibility of the theory that the Gallican liturgy was introduced into use by Irenaeus, bishop of Lyons (c. 130-200), who had learned it in the East from St Polycarp, the disciple of the apostle St John.

3. *Ambrosian Liturgy*.—Considerable variety of opinion has existed among liturgical writers as to the proper classification of the "Ambrosian" or "Milanese" liturgy. If we are to accept it in its present form, and to make the present position of the great intercession the test of its *genus*, then we must place it under Group V, the "Petrine," and consider it as a branch of the Roman family. If, on the other hand, we consider the important variations from the Roman liturgy which yet exist, and the still more marked and numerous traces of variation which confront us in the older printed and MS. copies of the Ambrosian rite, we shall detect in it an original member of the Ephesine group of liturgies, which for centuries past has been undergoing a gradual but ever increasing assimilation to Rome. We know this as a matter of history, as well as a matter of inference from changes in the text itself. Charlemagne adopted the same policy towards the Milanese as towards the Gallican Church. He carried off all the Milanese Church books which he could obtain, with the view of substituting Roman books in their place, but the completeness of his intentions failed, partly through the attachment of the Lombards to their own rites, partly through the intercession of a Gallican bishop named Eugenius (Mabillon, *Mss. Lat.*, i., ii. p. 106). It has been asserted by Joseph Vicoeques that this is an originally independent liturgy drawn up by St Barnabas, who first preached the gospel at Milan (*De Misse Ric.*, i. chap. xi., xii.), and this tradition is preserved in the title and proper preface for St Barnabas Day in the Ambrosian missal (Pamelius, i. 385, 386).

We can trace the following points in which the Milanese differs from the Roman liturgy, many of them exhibiting distinct lines of Ephesine or Eastern influence. Some of them are no longer found in recent Ambrosian missals, and only survive in the earlier MSS. published by Pamelius (*Liturgion*, tom. i. p. 298). Muratori (*Lit. Rom. Vet.*, i. 132), and Ceriani (in his edition, 1881, of an ancient MS. at Milan).

(a) The collect entitled "oratio super populum" corresponding to the *εὐχὴ μετὰ τὸ ἀνασθῆναι τὸ εὐχαρίσταν*; (b) the proclamation of silence by the deacon before the epistle; (c) the litanies and after the ingress (introid) on Sunday in Lent, closely resembling the Greek *Εκτενε*; (d) varying forms of introduction to the Lord's Prayer, in *Omnia Domini* (Ceriani, p. 116), in Pascha (ib., p. 124), (e) the presence of passages in the Prayer of Consecration which are not part of the Roman canon, and one of which at least corresponds in import and position though not in words to the Greek *Ἐπίκλησις*: *Ἰησὺν vero est, omnipotens Pater, mittens*, &c. (ib., p. 116); (f) the survival of a distinctly Gallican form of consecration in the Post-Sanctus: "in Sabbato Sancto": *Vere Sanctus, vere benedictus Dominus noster*, &c. (ib., p. 126); (g) the varying nomenclature of the Sundays after Pentecost; (h) the position of the fraction before the Lord's Prayer; (i) the omission of the second oblation after the words of institution (Muratori, *Lit. Rom. Vet.*, i. 138); (k) a third lesson or *Propheta* from the Old Testament preceding the epistle and gospel; (l) the lay offering of the oblations and the formula accompanying their reception (Pam., i. 297); (m) the position of the ablation of the hands in the middle of the canon just before the words of institution; (n) the position of the "oratio super populum" which corresponds in matter but not in name to the collect for the day before the Gloria in Excelsis.

4. *Galic Liturgy*.—We postpone the consideration of

this subject to a position under the heading of the liturgies of Great Britain and Ireland.

GROUP V. *St Peter, Italian, Rome*.—There is only one liturgy to be enumerated under this group, viz., the present liturgy of the Church of Rome, which, though originally local in character and circumscribed in use, has come to be nearly coextensive with the Roman Church, sometimes cuckoo-like ejecting earlier national liturgies, as in France and Spain, sometimes incorporating more or less of the ancient ritual of a country into itself, and producing from such incorporation a subclass of distinct uses, as in England, France, and North Italy. Even these subordinate uses have for the most part become, or are rapidly becoming, obsolete. The genius and policy of Rome are in favour of uniformity; and it requires no keen powers of vision to foretell that, liturgically speaking, she will be, before long, within all her dominions supreme.

The date, origin, and early history of the Roman liturgy are obscure. The first Christians at Rome were a Greek-speaking community, and their liturgy must have been Greek, and is possibly represented in the so-called Clementine liturgy. But the date when such a state of things ceased, when and by whom the present Latin liturgy was composed, whether it is an original composition, or, as its structure seems to imply, a survival of some intermediate form of liturgy,—all these are questions which are waiting for their solution, and to which no certain answer can be given, unless and until some further discovery shall be given of earlier liturgical remains.

One MS. exists which claims to represent the Roman liturgy as it existed in the time of Leo I., 440-61. It was discovered at Verona by Bianchini in 1735, assigned by him to the 8th century, and published under the title of *Sacramentarium Leonianum*; but this title was from the first purely conjectural, and is in the teeth of the internal evidence which the MS. itself affords, and is now being gradually abandoned. It is impossible here to enter into the minutiae of the evidence for this and other conclusions. The question is discussed at some length by Muratori, *Lit. Rom. Vet.*, i. chap. 3.

A MS. of the 9th or 10th century was found at Rome by Thomasius, and published by him in 1680 under the title of *Sacramentarium Gelasianum*. But it was written in France, and is certainly not a pure Gelasian codex; and, although there is historical evidence of that pope (492-96) having made some changes in the Roman liturgy, and although other MSS. have been published by Gerbertus and others, claiming the title of Gelasian, we neither have nor are likely to have genuine and contemporary MS. evidence of the real state of the liturgy in that pope's time.

The larger number of MSS. of this group are copies of the Gregorian sacramentary, that is to say, MSS. representing, or purporting to represent, the state of the Roman liturgy in the days of Gregory the Great (590-604). But they cannot be accepted as certain evidence, for the following reasons:—not one of them was written earlier than the 9th century; not one of them was written in Italy, but every one north of the Alps; every one contains internal evidence of a post-Gregorian date in the shape of masses for the repose or for the intercession of St Gregory, and in various other ways.

The Roman liturgy was introduced into England in the 7th, into France in the 9th, and into Spain in the 11th century. In France certain features of the service and certain points in the ritual of the ancient national liturgy became interwoven with its text, and formed those many varying medieval Gallican uses, which are associated with the names of the different French sees.

The distinguishing characteristics of the Petrine liturgy are these:—(a) the position of the great intercession within the canon,

the commemoration of the living being placed just before, and the commemoration of the departed just after, the words of institution, (b) the absence of the Epiclesis or Invocation of the Holy Spirit; (c) the position of the Pax or "Kiss of Peace" after the consecration and just before the communion, whereas in other liturgies it occurs at a much earlier point in the service.

Liturgies of the British Islands.

PERIOD I. The Celtic Church.—Until recently almost nothing was known of the character of the liturgical service of the vast Celtic Church which existed in these islands before the Anglo-Saxon conquest, and which continued to exist in Ireland, Scotland, Wales, and Cornwall for very considerable though varying periods of time after that event. But recently a good deal of light has been thrown on the subject, partly by the publication of the few genuine works of St. Patrick, Columba, Columbanus, and other Celtic saints; partly by the discovery of liturgical remains in the Scottish *Book of Deer*, and in the Irish *Books of Dimma and Mulling* and the *Stowe Missal*; partly by the publication of medieval Irish compendiums such as the *Leabhar Breac*, *Liber Hymnorum*, &c., which contain ecclesiastical calendars, legends, treatises, &c., of considerable but very varying antiquity. The evidence collected from these sources is sufficient to prove that the liturgy of the Celtic Church was of the Ephesine type. In central England the churches, together with their books and everything else belonging to them, were destroyed by heathen invaders from Jutland, Schleswig, and Holstein at the close of the 5th century; but the Celtic Church in the remoter parts of England, as well as in the neighbouring kingdoms of Scotland and Ireland, retained its liturgical independence for many centuries afterward.

An examination of its few extant service books and fragments of service books yields the following evidence of the Ephesine origin and character of the Celtic liturgy:—(a) The presence of whole collects and anthems which occur in the Gallican and Mozarabic but not in the Roman liturgy; (b) various formulae of thanksgiving after communion; (c) frequent addresses to the people in the form of Gallican *Præfationes*; (d) the Gallican form of consecration prayer, being a variable Post-Sanctus leading up to the words of institution; (e) the complicated rite of fraction as described in an Irish tract at the end of the *Stowe missal* finds its only counterpart in the elaborate ceremonial of the Mozarabic Church; (f) the presence of the Gallican ceremonial of *Pediluvium* or "Washing of Feet" in the earliest Irish baptismal office. For a further description of these and of other features which seem to be peculiar to the Celtic liturgy the reader is referred to Warren's *Liturgy and Ritual of the Celtic Church*, 1881.

PERIOD II. The Anglo-Saxon Church.—We find ourselves here on firmer ground, and can speak with certainty as to the nature of the liturgy of the English Church after the beginning of the 7th century. Information is drawn from the liturgical allusions in the extant canons of numerous councils, from the voluminous writings of Bede, Alcuin, and many other ecclesiastical authors of the Anglo-Saxon period, and above all from a very considerable number of service books written in England before the Norman Conquest. Three of these books are manuscript missals of more or less completeness, and, as none of them have yet been published, their names are appended:—(1) the Leofric missal, a composite 10th to 11th century MS., presented to the cathedral of Exeter by Leofric, the first bishop of that see (1046–1072), now in the Bodleian Library at Oxford; (2) the missal of Robert of Jumieges, archbishop of Canterbury (1061–52), executed probably at Winchester, and presented by Archbishop Robert to his old monastery of Jumieges in the neighbourhood of Rouen, in the public library of which town it now lies; (3) the Red Book of Derby, an incomplete missal of the second half of the 11th century, now in the library of Corpus Christi College, Cambridge.

A perusal of these volumes proves, what we should have expected *a priori*, that the Roman liturgy was in use in

the Anglo-Saxon Church. This was, no doubt, the case from the very first. That church owed its foundation to the forethought of a Roman pontiff, and the energy of a band of missionaries, headed by St. Augustine, who came directly from Rome, and who brought, as we are expressly assured by Bede, their liturgical codices with them from their native country (*Hist. Eccl.*, ii. 28). Accordingly, when we speak of an Anglo-Saxon missal, we mean a Roman missal only exhibiting one or more of the following features which differentiate it from an Italian missal of the same century.

(a) Rubrics, and other emblems of a miscellaneous character, written in the vernacular language of the country; (b) the commemoration of national or local saints in the calendar, in the canon of the mass, and in the litanies which occur on Easter eve, and in the baptismal offices; (c) the presence of a few special masses in honour of these national saints, together with a certain number of collects of a necessarily local character, for the rulers of the country, for its natural produce, &c.; (d) the addition of certain peculiarities of liturgical structure and arrangement interpolated into the purely Roman service from an extraneous source. There are two noteworthy examples of this in Anglo-Saxon service books. Every Sunday and festival, and almost every votive mass, has its proper *præface*, although the number of these *præfaces* in the Gregorian sacramentary of the same period had been reduced to eight. There were a large but not quite an equal number of triple episcopal benedictions to be pronounced by the bishop after the Lord's Prayer and before the communion. This custom must either have been perpetuated from the old Celtic liturgy, or directly derived from a Gallican source.

PERIOD III. Anglo-Norman Church.—The influx of numerous foreigners, especially from Normandy and Lorraine, which preceded, accompanied, and followed the Conquest, and the occupation by them of the highest posts in church as well as state, had a distinct effect on the liturgy of the English Church. These foreign ecclesiastics brought over with them a preference for and a habit of using certain features of the Gallican liturgy and ritual, which they succeeded in incorporating into the service books of the Church of England. One of these prelates named Osmund, a Norman count, earl of Dorset, chancellor of England, and bishop of Salisbury, 1078–99, undertook the revision of the English service books, and the missal which he produced in 1085, which we know as the *Sarum Missal*, or the *Missal according to the Use of Sarum*, practically became the liturgy of the English Church. It was not only received in the province of Canterbury, but was largely adopted beyond those limits—in Ireland in the 12th, and in various Scottish dioceses in the 12th and 13th centuries.

It would be outside the scope of a general article like the present to tabulate the numerous and frequently minute differences between medieval *Sarum* and the earlier Anglo-Saxon or contemporary Roman liturgy. They lie mainly in differences of collects and litanies, variations of ritual on Candlemas, Ash Wednesday, and throughout Holy Week, the introduction into the canon of the mass of certain clauses and usages of Ephesine character or origin, the words of rubrics in the eucharistic or imperpetrator's tone, the peculiar "Process in Prostrata," the procession of Corpus Christi on Palm Sunday, the forms of exorcism and reconciliation of penitents, &c. The varying episcopal benedictions as used in the Anglo-Saxon Church were retained, but the numerous proper *præfaces* were discarded, the number being reduced to ten.

Besides the famous and far-spreading use of *Sarum*, other uses, more local and less known, grew up in various English dioceses. In virtue of a recognized diocesan independence, bishops were able to regulate or alter their ritual, and to add special masses or commemorations for use within the limits of their jurisdiction. The better known, and the more distinctive of these uses were those of York and Hereford, but we also find traces of, or allusions to, the uses of Bangor, Lichfield, Lincoln, Ripon, St. Asaph, St. Paul's, Wells, and Winchester.

Other Service Books.—The Eucharistic service was contained in the volume called the *MISSAL* (q. v.), as the ordinary choir offices were contained in the volume known as the *BREVETARY* (q. v.). But besides these two volumes there were a large number of other service books. Mr. Maskell has enumerated and described ninety-one such volumes in the use of the Western Church only. It must be understood, however, that many of these ninety-one names are synonyms (*Mon. Lit. Eccl. Anglo*, 1846, vol. i. p. ccxv.). The

list might be increased, but it will be possible here only to name and describe a few of the most important of them. (1) *Agnus-Rituale*. (2) The *Antiphonary* contained the antiphons sung at the canonical hours, and contain other minor portions of the service. (3) The *Benedictional* contained those triple episcopal benedictions previously described as used on Sundays and the chief festivals throughout the year. (4) The *Collectary* contained the collects for the seasons, together with a few other parts of the day offices. It was an inchoate Breviary. (5) The *Epistolarium* contained the epistles, and (6) the *Evangelistarium* the gospels for the year. (7) The *Gradual* contained the introt, gradual, sequences, and the other portions of the canonical service which at high mass were sung by the choir. (8) The *Litania* contained the lessons read at mass and at other times, and may be taken as a generic term to include the *Homiliarium*, *Martyrology*, *Psalms*, and other volumes. (9) The *Manual* was the term usually employed in England to denote the *Rituale*. (10) The *Penitential* contained the order of ordination, consecration, and such other rites as could, ordinarily, only be performed by the bishop. (11) The *Rituale* or *Ritual* comprised the occasional offices for baptism, marriage, burial, and those other offices which it ordinarily fell to the lot of the parish priest to execute. To these we must add a book which was not strictly a church office book, but a handy book for the use of the laity, and which was in very popular use, and often very highly embellished in the 14th to 16th century, the *Book of the Hours*, or *Horæ Beate Marci Virginitatis*. It contained portions of the canonical hours, litanies, the penitential psalms, and other devotions of a miscellaneous and private character.

The Eastern Church, too, possessed and still possesses numerous and voluminous office books, of which the chief are the following:—The *Euchologion*, containing the liturgy itself with the remaining sacramental offices bound up in the same volume, the *Horologion*, containing the surviving portion of the Breviary, the *Menologion* being equivalent to a complete Breviary, the *Menologion*, or martyrology, the *Octoechos* and *Parastaseis*, containing Tropars, and answering to the Western Antiphonary, the *Pentecostarion*, containing the services from Easter Day to All Saints' Sunday, as the *Troparion* contained those from Septuagesima to Sunday after Pentecost. The *Typicon* was a general book of rubrics corresponding to the Ordinale or the Pie of Western Christendom.

PERIOD IV. The Reformed Church.—The liturgy of the English Church passed through a more marked phase of change in the 16th century than during any of those periods which we have briefly described. The desire for some reform, and the sense of its necessity, which had been manifesting itself in various ways for more than a century and a half, culminated in the reign of Edward VI., and caused the appearance, with the full sanction of church and state, of the First Prayer Book of Edward VI. which was published on March 7, 1549, and came into general use on the feast of Whitsunday, June 9, 1549. Without attempting to enumerate particular points, we will summarize the general features which marked this change, and will exhibit the gains of such a reform, which, from an Anglican point of view, constitutes its complete justification.

(a) Simplification in the number and character of books required for divine service. The Prayer Book is a compendium of most of the volumes which have been recently named and described. Its matins and evensong are a compilation from the Breviary, the office of Holy Communion, with the collects, epistles, and gospels, is a translation and adaptation of the missal; the occasional offices represent the ritual or manual, and the offices of consecration and of ordination are taken, with modifications, from the position.

(b) The removal from the service of a vast quantity of legendary matter which was read in the form of lessons, and which was objectionable partly because it was unauthoritative, partly because it was indorous and almost profane. As an instance of unauthoritative matter, we quote a passage in the fourth lesson for the festival of St. Silvester, December 31, bishop of Rome, 314–335—

"In which office of the priesthood he (Silvester) dissembled himself above the rest of the clergy, and afterwards received Melchisedec on the papal throne in the reign of Constantine. That day he was ordered from heaven, and in order to care himself, by the advice of his physicians he ordered a bath to be prepared of infant's blood. But the holy apostles Peter and Paul appeared to him in private, and told him that, if he wished to be free from his journey, he should obtain the man's plan of an impious bath, and send for Silvester dwelling in seclusion at Monte Sineone, that by him the emperor should be refreshed in the bath of salvation, and should order temples to be built in every province of the Roman empire after the fashion of the Christians, and that he should do away with the images of idols, statues, and ornaments, the worship of the true God. Constantine, therefore, in obedience to the divine command, made diligent search for and summoned Silvester, by vision, recognizing the description of the apostles, he was baptized, and inclined to defend and defend his religion."

This lesson retains its position in the present Roman Breviary, although its unauthoritative character can be abundantly proved and

is generally acknowledged. The Breviary in fact is still, and was even more so then, full of legends which once passed for but have long since been abandoned as history.

As examples of the ludicrous we quote the first lesson for the festival of St. Felix from the Aberdeen Breviary of 1609, fol. xxvii., and the eighth lesson for the festival of St. Serf from the same Breviary (July 5, fol. xvi.)—

"His (Felix) was born, as it was foretold of him, with a stone in his mouth, on account of which he was so deplored by his father that he was ordered immediately after his birth to be thrown into a neighboring pond and drowned. In this pond he was miraculously nourished by angels for a whole year. But after the lapse of a year he was found by Bishop Iudica, to whom a divine revelation of the fact had been given, playing among the angels. He was taken out of the pond safe and sound, was baptized, and afterwards became distinguished in sacred literature."

"A certain robber called out one day a sheep which used to live and feed in the house of St. Serf, and killed it and ate it. Diligent inquiry was made for the thief but without success. At length suspicion fell on the robber, and he hastened into St. Serf's presence, prepared to deny the accusation with an oath. He swore a big oath that he was innocent of the charge laid against him, when, wonderful to relate (a fact which would not be believed on merely human testimony), the sheep which had lately been eaten began to baw in the stomach of the robber. Whereupon in confusion the man fell prostrate to the ground, and humbly asked for pardon, and the saint prayed for him."

There was also a quantity of objectionable matter introduced by a process of adaptation, or sometimes, as it was technically termed, by a process of farrago, into the older prayers. The *Canon* in English in the Sarum Missal is preserved almost unchanged in edit. i, 1641, p. 686—the faced words are represented by italics—

"Qui tollis peccata mundi, auscipe deprecationem nostram, ad Mariam gloriam. Qui sedes ad dexteram Patris, miserere nobis. Quoniam tu solus sanctus, Mariam sanctificans. Tu selus Dominus, Mariam gubernans. Tu solus altissimus, Mariam coronans. Jesu Christe, cum Sancto Spiritu in gloria Dei atri. Amen."

(c) For the first time, so far as can be ascertained, in the history of the English Church, the vernacular tongue was employed

(d) The numerous litanies to and invocations of the saints, especially of the Virgin Mary, were expunged.

(e) There was a very great extension of the portion of Holy Scripture read in divine service, partly by the extension of non-Scriptural matter, partly by the lengthening of lessons which sometimes consisted only of one or two verses, so "that many times there was more business to find out what should be read than to read it when it was found out."

(f) There was a general simplification of the services, by the reduction of the number of saints' days, by the cutting away of antiphons, invitatories, and responses, by the compression of the seven canonical hours into the two daily services of matins and evensong, &c.

(g) The various offices for the dead were abolished, and numerous prayers which involved a belief in the medieval idea of the penal flames of purgatory made way for the present burial office and the commemoration of the departed in the Eucharistic service.

The first reformed Prayer Book of 1549 remained in use till 1552, when by Act of Uniformity passed on April 6 it was ordered that a further reformed Prayer Book should come into general use on the feast of All Saints (November 1) following. This second Prayer Book, commonly spoken of as the Second Prayer Book of King Edward the VI., marks the furthest point in the Puritan direction which was ever reached by the liturgy of the Church of England. An idea of its character may be gained by mentioning some of the features retained in the first and discarded in the Second Prayer Book, and some of the features added in the Second, but absent from the First Prayer Book.

In the former class are—(a) the sign of the cross used in consecration, confirmation, marriage, and visitation of the sick, (b) the use of exorcism, chrism, and chrism in baptism; (c) unction of the sick, (d) certain prayers for the dead, and a special Eucharist for funerals; (e) the mention of vestments with alms and tuns for Eucharistic use, and of the pastoral staff and cope for the morning and evening prayer, (f) the addition of the Jubilate, Cantata, and Deus Meus at alternative canticles; (g) the words "commonly called the mass" omitted from the title of Holy Communion; (h) the words "mutant here on earth" added to the title of the prayer for the whole state of Christ's Church; (i) the deacon's introduction at the commencement of the communion service; (j) the second clause in the formula of sacramental distribution was substituted for the first, the two being subsequently combined in 1569. These are merely samples out of many more points which might be named.

It has not been ascertained that this Prayer Book ever received the sanction of Convocation, and it probably never came into complete use. Such use was in any case short-lived, for Edward VI. died on July 6, 1553, and the English Prayer Book was abolished and the Latin missal restored to use by one of the first Acts of Queen Mary, in October 1553. Queen Mary died on November 17, 1558, and another complete change of policy took place. The reformed Prayer Book was brought into use again on June 24, 1559, not in the exact shape which it bore in 1553, but with various modifications, which we forbear to enumerate in detail. It may be said of them, as of the various alterations introduced subsequently into the Prayer Book, that their general tendency was conservative rather than destructive, and in a Catholic rather than in a Protestant direction. The next important revisions of the Prayer Book took place in 1604, under James I., after the Hampton Court Conference, and in 1661-62, after the restoration of Charles II. The Book of Common Prayer had been abolished under the Commonwealth, and it could only be used under the risk of heavy penalties from 1645 to 1661. It was now restored with a considerable number of additions and alterations, after having been discussed without any satisfactory result between churchmen and Puritans at the Savoy conference in 1661. When these had received the sanction of the Convocations of Canterbury and York, it was attached to an Act of Uniformity which received the royal assent on May 19, 1662, by the provisions of which Act it came into general use on St. Bartholomew's Day, August 24, 1662. Since that date, although various slight changes have been made in recent years, nothing has been done amounting to a revision or new edition of the Prayer Book, or demanding notice in these columns.

A few words are added about other national versions of the reformed liturgy.

The Liturgy of the Scottish Episcopal Church.—This liturgy in nearly its present form was compiled by Scottish bishops in 1636, and imposed, or, to speak more accurately, attempted to be imposed upon the Scottish people by the royal authority of Charles I. in 1637. The prelates chiefly concerned in it were Spottiswood, bishop of Glasgow; Maxwell, bishop of Ross; Wedderburn, bishop of Dunblane; and Forbes, bishop of Edinburgh. Their work was approved and revised by certain members of the English episcopate, especially Laud, archbishop of Canterbury; Juxon, bishop of London; and Wren, bishop of Norwich. This liturgy has met with varied fortunes, and passed through several editions. It is now used as an alternative form with the English communion office in the Scottish Episcopal Church.

Among its more noteworthy features are—(a) the retention in its integrity and in its primitive position after the words of institution, of the invocation of the Holy Spirit;¹ (b) the reservation of the sacrament is permitted for the purpose of communicating the absent or the sick; (c) the mixed chalice is explicitly ordered; (d) the minimum number of communicants is fixed at one or two, instead of three or four. The general arrangement of the parts approximates more closely to the First Prayer Book of Edward VI. than to the present Anglican Book of Common Prayer.

The American Liturgy.—The Prayer Book of the "Protestant Episcopal Church" in America was adopted by the General Convention of the American Church held in 1789. It is substantially the same as the English Book of Common Prayer, but among the more important variations we may

name the following:—(a) the arrangement and wording of the communion office rather resembles that of the Scottish than of the Anglican liturgy, especially in the position of the oblation and invocation immediately after the words of institution; (b) the Magnificat, Nunc Dimittis, and Athanasian creed are disused; (c) ten selections of psalms are appointed to be used as alternatives for the psalms of the day. In addition to these there are various verbal and other unimportant alterations.

The Irish Prayer Book.—The Prayer Book in use in the Irish portion of the United Church of England and Ireland was the Anglican Book of Common Prayer, but after the disestablishment of the Irish Church several changes were introduced into it by a synod held in Dublin in 1870. These changes included (a) the exclusion of all lessons from the Apocrypha, (b) of the rubric ordering the recitation of the Athanasian creed, (c) of the rubric ordering the vestments of the second year of Edward VI., (d) of the form of absolution in the office for the visitation of the sick, (e) the addition of one question and answer in the Church Catechism, bringing out more clearly the spiritual character of the real presence.

The Presbyterian Church.—The Presbyterian churches of Scotland at present possess no liturgy properly so called. Certain general rules for the conduct of divine service are contained in the "Directory for the Public Worship of God," agreed upon by the Assembly of Divines at Westminster, with the assistance of commissioners from the Church of Scotland, approved and established by an Act of the General Assembly, and by an Act of Parliament, both in 1645. In 1654 John Knox had drawn up an order of liturgy, closely modelled on the Genevan pattern, for the use of the English congregation to which he was then ministering at Frankfurt. On his return to Scotland this form of liturgy was adopted by an Act of the General Assembly in 1660, and became the established form of worship in the Presbyterian Church, until the year 1846, when the Directory of Public Worship took its place. Herein regulations are laid down for the conduct of public worship, for the reading of Scripture, and for extempore prayer before and after the sermon and in the administration of the sacraments of baptism and the Lord's supper, for the solemnization of marriage, visitation of the sick, and burial of the dead, for the observance of days of public fasting and public thanksgiving, together with a form of ordination, and a directory for family worship. In all these cases, although the general tenor of the prayer is frequently indicated, the wording of it is left to the discretion of the minister, with these exceptions:—at the act of baptism this formula must be used—"I baptize thee in the name of the Father, and of the Son, and of the Holy Ghost;" and for the Lord's Supper these forms are suggested, but with liberty to the minister to use "other like, used by Christ or his apostle upon this occasion:—"

"According to the holy institution, command, and example of our blessed Saviour Jesus Christ, I take this bread, and, having given thanks, break it, and give it unto you. Take ye, eat ye; this is the body of Christ which is broken for you; do this in remembrance of him." And again, "According to the institution, command, and example of our Lord Jesus Christ, I take this cup and give it unto you; this cup is the New Testament in the blood of Christ, which is shed for the remission of the sins of many; drink ye all of it."

There is also an unvarying form of words directed to be used before the minister by the man to the woman and by the woman to the man in the case of the solemnization of matrimony. The form of words on all other occasions, including ordination, is left to the discretion of the officiating minister, or of the presbytery.

Continental Protestant Churches. The Calvinistic Churches.—Rather more of the liturgical element, in the shape of a set form of

¹ The present clause runs thus:—"And we most humbly beseech thee O merciful Father to hear us, and of Thy almighty goodness vouchsafe to bless and sanctify with Thy word and Holy Spirit these and Thy gifts and creatures of Bread and Wine, that they may become the Body and Blood of Thy most dearly-beloved Son." This petition is found in the Brevier but not in the Roman or Anglican Breviers.

words, enters into the service of the French and German Calvinistic Protestants. The Sunday morning service, as drawn up by Calvin, was to open with a portion of Holy Scripture and the recitation of the Ten Commandments. Afterwards the minister, inviting the people to accompany him, proceeded to a confession of sins and supplication in grace. Then one of the Psalms of David was sung. Then came the sermon, prefaced by an extempore prayer and concluding with the Lord's Prayer, creed, and benediction. The communion service began with an exhortation leading up to the apostle's creed, then followed a long exhortation, after which the bread and cup were distributed to the people, who sat down in rows and on either side, while a Psalter was sung as on a suitable passage of Scripture was being read. After all had communicated a set form of thanksgiving was said by the minister. Then the hymn of Simon was sung by the congregation, who were then dismissed with the blessing. The form of service has been modified in various ways from time to time, but it remains substantially the type of service in use among the Reformed Churches of Germany, Switzerland, and France.

The Lutheran Church.—Luther was far more conservative than the rest of the Protestant Reformers, and his conservatism appeared nowhere more than in the service books which he drew up for the use of the church which bears his name. In 1523 he published a treatise *Of the Order of the Service in the Congregation*, and in 1526 he published the *German Mass*. Except that the vernacular was substituted for the Latin language, the old Massbook and order of the Roman Mass were closely followed, beginning with the Confiteor, Introit, Kyrie Eleison, Gloria in excelsis, &c. The text of this and other Lutheran services is given in *Agende für christliche Gemeinden des lutherischen Bekenntnisses*, Nordhagen, 1858. At the same time Luther was tolerant, and expressed a hope that different portions of the Lutheran Church would from time to time make such changes or adaptations in the order of service as might be found convenient. The Lutheran Churches of northern Europe have not been slow to avail themselves of this advice and permission. Most of them have drawn up liturgies for themselves, sometimes following very closely, sometimes differing considerably from the original service composed by Luther himself. In 1828, on the union of the Lutheran and Reformed (Calvinistic) Churches of Prussia, a new liturgy was published at Berlin. It is used in its entirety in the chapel royal, but great liberty as to its use was allowed to the parochial clergy, and considerable variations of text appear in the more recent editions of the service book.

The Swedes, Danes, Livonians, and other Protestant bodies have drawn up liturgies for themselves, but they are hardly of sufficient historical importance to be described at length here.

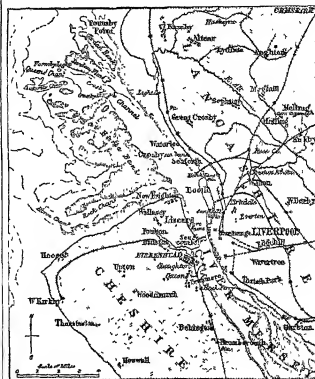

The Old Catholics, finally, published a *Rituale* in 1870 containing the occasional offices for baptism, matrimony, burial, &c., and a text for reception of holy communion, in the German language. The latter is for temporary use in anticipation of a revised and not yet published massal, corresponding to the order of communion in English published March 8, 1848, in anticipation of the complete office in the Prayer Book of 1849. (F. E. W.)

LUTPRAND (c. 922–972), Italian chronicler, was born towards the beginning of the 10th century, of a good Lombard family. The name is sometimes spelled Lutprand and even Luitprand. In 931 he entered the service of King Hugo of Italy as page, he afterwards rose to a high position at the court of Hugo's successor Berengar, having become chancellor, and having been sent (949) on an embassy to the Byzantine court. Falling into disgrace with Berengar, he attached himself to the emperor Otto I., whom in 961 he accompanied into Italy, and by whom in 962 he was made bishop of Ciemousa. He was frequently employed in missions to the pope, and on two occasions (968, 971) to Byzantium, to negotiate on behalf of the younger Otto (afterwards Otto II.) for the hand of Theophano. Lutprand died in 972.

He wrote (1) *Antipodesta, seu romanorum per Europam gestarum, Libri 87*, an historical narrative, relating to the events from 887 to 949, compiled, as its name almost implies, with the object of avenging himself upon Berengar and Wala his queen; (2) *Historia Ottonis*, unfortunately covering only the years from 960 to 961, and (3) *Relatio de Legatione Constantinopolitana* (968–969). All are to be found in the *Monum. Germ. Hist. of Pertz*, and in the *Rer. Ital. Script.* of Muratori; there is a recent edition by Dümmler (1877), and a partial translation into German, with introduction by Wattenbach, is given in the second volume of the *Geschichte schreiben der Deutschen Prosa* (1893). Compere Wattenbach, *Deutsche Geschichtsschreiber im Mittelalter* (3d ed., 1878). Three other works, entitled *Adversus Arrianos*, *Chronicon* (904–960), and *Opusculum de vita Romanorum pontificum*, are usually, but wrongly, assigned to Lutprand.

LIVERPOOL, a city and seaport of England, in the hundred of West Derby, in the county palatine of Lancashire, situated on the right bank of the estuary of the Mersey, about three miles from the open sea. The form of the city is that of an irregular semicircle, having the base line formed by the docks and quays extending about six miles along the east bank of the estuary, which here runs nearly north and south, and is about a mile in breadth. On the north the city is bounded by the borough of Bootle, along which the line of docks is continued. The area of the city is 5210 acres.

General Aspect and Features.—The suburb of Liverpool is the Hunter stratification of the New Red Sandstone, overlying the Coal-measures, which rise up some distance to the eastward. In the lower districts there is a deposit of boulder clay, which has been extensively used for the manufacture of bricks. The sandstone rises in long ridges to the eastward, in the highest points about 250 feet above the sea level. The city therefore lies on a continuous

Port of Liverpool

slope varying in gradient, but in some districts very steep. Exposed to the western sea breezes, with a dry subsoil and excellent natural drainage, the site is naturally salubrious, but neglect and perverseness have in past times done much to neutralize these advantages. The old borough, lying between the pool and the river, was a conglomeration of narrow alleys and mean houses packed together without any regard to sanitary provisions; and during the 16th and 17th centuries it was several times visited by the plague, which carried off many of the inhabitants. When the town burst its original limits, and expanded up the slopes beyond, a better state of things began to exist. The older parts of the town have at successive periods been entirely taken down and renovated. The streets of shops—Church Street, Bold Street, &c.—are equal in display to similar establishments in London. The commercial part of the city is remarkable for the number of palatial-looking piles of offices, built of hewn stone, principally in the Italian Renaissance style, amongst which the banks and insurance offices stand pre-eminent. The

demand for cottages about the beginning of the present century led to the construction of what are called "cous," being narrow *clos de ses*, close packed, with no thorough ventilation. This, combined with the degraded habits of a population brought together indiscriminately, resulted in a very high rate of mortality, to contend with which enormous sums have been expended in sanitary reforms of various kinds. The more modern cottages, erected on the higher grounds, are all that can be desired for that class of habitation.

Parks—The public parks of Liverpool now form a

prominent feature in the aspect of the town. The earliest, the Prince's Park, was laid out in 1843 by private enterprise. Seton Park, the most extensive, containing about 400 acres, was commenced in 1865, and completed at a cost of £410,000. A large portion of the land round the margin has been leased for the erection of villas. Waver-tree, Newsam, Sheil, and Stanley Parks have also been constructed at the public expense. Connected with Waver-tree Park are the botanic gardens, with the usual plant houses, and a large and lofty palm house. The suburbs are rapidly extending, and those on the south contain many

Plan of Liverpool.

good private residences. A boulevard, about a mile in length, planted with trees in the centre, leads to the entrance to Prince's Park.

Public Buildings—The old town has been so completely renovated during the present century that scarcely any of the public buildings date from an earlier period.

The earliest, and in many respects the most interesting, is the town-hall in Castle Street. This was erected from the designs of John Wood, the architect of the squares and crescents of Bath, and was opened in 1754. The building has since undergone considerable alterations and extensions, but the main features remain unchanged. It is a classical rectangular stone building in the Corinthian style, with an advanced portico in front, and crowned with a lofty dome

surmounted by a seated statue of Minerva. The interior was destroyed by fire in 1795, and was entirely remodelled in the restoration. It now contains a splendid suite of apartments, including a ball-room about 100 feet by 60, approached by a noble staircase. The building is occupied by the mayor as the municipal mansion house. A range of municipal offices was erected in Dale Street in 1860. The building is in the Palladian style, of considerable extent and imposing design, with a dominating tower and square pyramidal spire.

The crowning architectural feature of Liverpool is St George's Hall, completed in 1854. The original intention was to erect a music hall suited for the triennial festivals which had been periodically held in the town. About the

same time the corporation proposed to erect law courts for the assizes, which had been transferred to Liverpool and Manchester. In the competitive designs, the first prize was gained in both cases by Harvey Lonsdale Elmes. He was employed to combine the two objects in a new design, of which the present building is the outcome.

The structure is one of which the city may well feel proud, and notwithstanding some defects it will always hold a high and honourable place amongst the erections of modern times. It is fortunate in its situation, occupying the most central position in the town, and surrounded by an area sufficiently extensive to exhibit its proportions to the best advantage. Another advantage it possesses is that of size; there are few buildings in the country, forming a solid mass under one roof, which surpasses it in dimension. The plan is simple in arrangement, and easily described. The centre is occupied by the great hall, 169 feet in length, and, with the galleries, 27 feet wide and 74 feet high, covered with a solid vault in masonry. Attached to each end, and opening therefrom, are the law courts. A corridor runs round the hall and the courts, communicating with the various accessory rooms. Externally the east front is faced with a fine portico of sixteen Corinthian columns about 60 feet in height. An advanced portico of similar columns fronts the south end crowned with a pediment filled with sculpture, with the inscription—

"Arthas, Legibus, Censitibus
Locum Municipia Constituitur
Anno Domini MCCCCLXXII."

The style is Roman, but the refinement of the details is suggestive of the noblest period of Grecian art.

The great hall is finished with considerable richness in polished granite columns, marble balustrades and pavements, polished brass doors with rich foliated tracery, &c. The organ, built by Messrs Willis of London, from the specification of Mr Samuel Wesley, is equal to any in the country for extent, power, and beauty of tone. Mr Elmes, a young architect of great promise, having died during the progress of the work, the building was completed by the late Mr O. R. Cockrell, R.A.

Next to the public buildings belonging to the city, the most important is the exchange, forming three sides of a quadrangle, adjoining the town-hall on the north side. The town-hall was originally built to combine a mercantile exchange with municipal offices, but the merchants perversely preferred to meet in the open street adjoining. Thus, with other circumstances, led to the erection of the new exchange, a building of considerable merit, which was commenced in 1803 and opened in 1808. It had scarcely been in use for more than fifty years when it was found that the wants of commerce had outstripped the accommodation, and the structure was taken down to make room for the present building, in which greater convenience has been attained, with considerable sacrifice of æsthetic effect.

The revenue buildings, commenced in 1838, on the site of the original Liverpool Dock, combine the customs, inland revenue, post-office, and dock board departments. It is a huge heavy structure, with three advanced porticoes in the *Ilyssus* Ionic style. Near by stands the sailors' home, a large building in the Semi-Gothic or Elizabethan style.

The Philharmonic Hall in Hope Street, with not much pretension externally, is one of the finest music rooms in the kingdom, it accommodates an audience of about 2500.

The group of buildings forming the free public library, museum, and gallery of art are finely situated on the brow of the slope opposite St George's Hall. The library and gallery of art are separate buildings connected by the circular reading-room in the middle. The latter possesses some novelties in construction, having a circular floor 100 feet in diameter without columns or any intermediate support, and a lecture-room underneath, amphitheatrical in form, with grades or benches hewn out of the solid rock.

Railways.—There are three passenger stations in Liverpool, the London and North-Western, the Lancashire and Yorkshire, and the combined station of the Midland, Great Northern, and Manchester and Sheffield. The rapid increase of traffic has led to large extensions of the North-Western, and a very large addition to the Lancashire and Yorkshire is in progress (1892). The tunnel under the

Mersey now in course of construction will give access for the Great Western and Cumbrian systems into Liverpool.

Water and Gas Supply.—The original supply of water was from wells in the sandstone rock, but in 1846 an Act was passed, under which extensive works were constructed at Hvington, about 25 miles distant, by which a much larger supply was obtained. The vast increase of population led to further requirements, and in 1880 another Act gave power to impound the waters of the Vyrnwy, one of the affluents of the Severn. This scheme which, it is expected, will give a copious supply for many years to come, is now being carried out. The gas-works are the property of a company. Efforts have been made to effect a purchase by the city, but hitherto without success.

Administration of Justice.—The city has quarter sessions for criminal cases, presided over by the recorder, but the sessions are really held eight times in the year. The court of passage for civil cases is a very ancient institution, dating from the foundation of the borough by King John, originally intended for cases arising out of the imposts and exports passing through. Its jurisdiction has been confirmed and settled by parliament, and it is now competent, by consent, to try causes to any amount. The mayor is nominally the president, but the actual judge is an assessor appointed by the crown. There are two police courts which sit daily, one presided over by the lay magistracy, the other by the stipendiary magistrate.

Eccelesiastical.—The parish, which was separated from Walton-on-the-Hill in 1699, contained two churches, St Nicholas, the ancient chapel, and St Peter's, then built. There were two rectors, the living being held in mediæties. Over recent years changes have been sanctioned by parliament. The living is now held by a single incumbent, and a large number of the churches which have since been built have been formed into parishes by the ecclesiastical commissioners. St Peter's has been constituted the pro-cathedral, pending the erection of a more suitable building. Besides the two original parish churches, there are sixty-seven others belonging to the establishment.

The Roman Catholics form a very numerous and powerful body in the city, and it is estimated that from a third to a fourth of the entire population are Catholics. A large part of these are Irish settlers or their descendants, but this district of Lancashire has always been a stronghold of Catholicism, many of the landed gentry belonging to old Catholic families.

Charities.—These are numerous, and are maintained with no niggardly hand. The earliest foundation is the Blue Coat hospital, established in 1708, for orphans and fatherless children born within the borough. The building, erected in 1717, is a quaint and characteristic specimen of the architecture of the period. It now maintains two hundred and fifty boys and one hundred girls. There is an orphan asylum, established in 1840, for boys, girls, and infants, and a seamen's orphan asylum, commenced in 1858, for boys and girls. The Roman Catholics have similar establishments. The medical charities are large and flourishing. The royal infirmary has had a school of medicine attached, which has been very successful, and is now merged in the new University College. The medical charities are aided by simultaneous collections in the churches and chapels on "Hospital Sunday," the first Sunday in the year, the amount averaging about £10,000.

Literature, Art, and Science.—The free library, museum, and gallery of arts, established and managed by the city council, was originated in 1850. The library building was erected by Sir William Brown at a cost of £40,000. The Derby museum, containing the collections of Edward, the thirteenth earl, were presented by his son. The Mayer museum of historical antiquities and art was non-

tributed by Mr Joseph Mayer, F.S.A. Sir Andrew Walker erected the art gallery which bears his name at an expense of £35,000. The Fiction circular reading-room, and the Rotunda lecture-room were built by the corporation at the cost of £25,000. The library contains nearly 100,000 volumes. An annual exhibition of paintings has been established, the sales from which average about £12,000 per annum. A permanent gallery has also been formed, which is now being enlarged at a cost of about £12,000.

The literary and philosophical society was established in 1812, and still flourishes. There are also philomathic, geological, chemical, historic, and various other societies for the cultivation of almost every branch of knowledge and inquiry. An art club has been established with great success, and possesses an excellent club-house and gallery. The royal institution, established by Roscoe in 1817, possesses a fine gallery of early art, and is the centre of the various literary institutions of the town.

Education.—Elementary education has always met with cordial support in Liverpool, and is now carried on with vigour by the school board, supplemented by voluntary schools. For middle class and higher education there have existed for many years three institutions, which have been very successful, viz., the school attached to the royal institution, the collegiate institution in Shaw Street, and the Liverpool institute high school. A further effort has been successfully made resulting in the foundation of University College, the inaugural meeting of which was held on January 14, 1882. This college is affiliated to the Victoria university of the north-west of England. The sum of £135,000 has been raised by voluntary subscription, to which £30,000 have been contributed by the corporation. Seven chairs have been endowed, and professors appointed, and a suitable building has been provided.

Recreation and Social Life.—There are eight theatres, besides many minor music halls and places of amusement. The most fashionable and exclusive is the Philharmonic Hall, which is a large handsome building open only to proprietors, whose concerts take place every fortnight during the season. The Philharmonic concerts, and the balls at the Wellington Rooms (the Almshouses of Liverpool), afford the principal opportunities for the gatherings of the fashionable world. The Alexandra theatre, the new Court theatre, the Prince of Wales theatre, and Hengler's circus are all that could be desired in point of decoration and the *mises en scene*. The minor houses are conducted on the whole with great propriety and success.

Population.—According to the census of 1881 (preliminary report) the number of inhabitants within the parliamentary and the municipal borough—the limits of which are continuous—amounted to 552,425 persons, 271,640 being males and 280,785 females. At the end of the 17th century the population of Liverpool was 5145, but since then it has steadily increased as follows:—

1710	8,168	1811	94,876
1720	10,446	1821	126,000
1738	23,000	1831	205,672
1769	84,000	1871	488,425
1785	100,000	1881	552,425
1801	177,658		

If the boroughs of Bootle and Birkenhead, which are component parts of the port, are included, Liverpool has now a population of about three quarters of a million.

Trade and Commerce.—The progress of the commerce of Liverpool during the present century is almost without a parallel. In 1800 the tonnage of ships entering the port was 450,060, in 1880 it reached 7,938,620 tons. In 1800 4746 vessels entered, averaging 94 tons; in 1880 there were 20,246, averaging 440 tons. The only British port which can at all come into competition with Liverpool is London, the total tonnage of which, comprising exports and imports, amounted in 1880 to 10,479,106 tons, against 14,496,384

in Liverpool. A large proportion of this, however, is a coasting trade, indicated by the smaller size of the ships, averaging 340 tons each in London as compared with 440 tons in Liverpool. The coasting trade in Liverpool has rather fallen off owing to the superior advantages of railway traffic. The proportion of steamers to sailing ships has very largely increased of late years. The return for 1881 gives 5,684,469 tons of steam navigation to 2,379,466 tons in sailing ships. If we take the value of the imports as a criterion, London is far in advance of Liverpool, the values in 1880 being £141,442,907 and £107,460,187, but the London imports consist, to a great extent, of what the Liverpool imports, such as tea, silk, indigo, wines, &c., whilst the Liverpool imports principally consist of grain, food, and raw produce, the materials for manufacture. If we look at the exports the balance is reversed, Liverpool, in 1880, having exported the value of £84,029,851, against £52,600,928 from London. In the number of ships registered as belonging to the port, Liverpool stands first in the world, the tonnage belonging to Liverpool being 1,561,871, against 1,120,869 in London, and 1,005,884 in the whole of the ports on the Clyde.

The commerce of Liverpool extends to every part of the world, but probably the intercourse with America stands pre-eminent, there being five lines of steamers to New York alone, besides lines to Philadelphia, Boston, Halifax, Canada, New Orleans, &c. The size of the ships has greatly increased, having reached 8000 tons burden, with 10,000 horse-power.

The imports into Liverpool comprise produce of every description from every region under the sun. Cotton, however, is the great staple, almost the whole trade of the commodity centring here. Grain comes next, American and Australian corn occupying a large proportion of this market. Within the last few years an enormous trade in American provisions, including live cattle, has sprung up. Tobacco has always been a leading article of importation. In regard to exports, Liverpool possesses decided advantages; lying so near the great manufacturing districts of Lancashire and the West Riding of Yorkshire, this port is the natural channel of transmission for their goods, and, if everything else fails, there are always coal and salt from Wales and Cheshire ready to make up a cargo. The consequence is that many ships, after discharging their home-ward cargoes at London and the eastern ports, come round in ballast to Liverpool for an outward cargo.

Manufactures.—The manufactures of Liverpool are not extensive. Attempts have been repeatedly made to establish cotton-mills in and near the city, but have resulted in uniform failure. Engineering works, especially as connected with marine navigation, have naturally grown up, and have been carried on successfully on a large scale. Shipbuilding, in the days of the old wooden walls, in the early part of the present century, was active and prosperous. Several frigates and sloops-of-war for Government having been built here, but the keen competition of the Clyde and the north of England drew away a large portion of the trade. There are now four shipbuilding establishments on the Mersey. In the year 1880-81 there were launched from these yards thirty-three iron ships, with a tonnage of 58,971 tons. At one period the soap manufacture filled a large space in the industry of Liverpool, but it has almost entirely departed. During the latter half of last century and the beginning of the present, the pottery and china manufacture flourished in Liverpool. John Sadler, a Liverpool manufacturer, was the inventor of printing on pottery, and during the early period of Joseph Wedgwood's career, all his goods which required printing had to be sent to Liverpool. A large establishment, called the Herculaneum Pottery, was founded in an suburb on the bank of the Mersey, and was carried on with success for many years, but the whole trade has long disappeared. One manufacture established at an early period, still continues to flourish—the watch and chronometer trade. Litherland, the inventor of the lever watch, was a Liverpool manufacturer, and Liverpool-made watches have always been held in high estimation. There are several extensive sugar refineries, and two large tobacco manufactures.

Docks.—The docks of Liverpool on both sides of the Mersey are under the same trust and management, and equally form part of the port of Liverpool. On the Liverpool side they extend along the margin of the estuary of 6 miles, of which 14 miles is in the borough of Bootle. The Birkenhead docks have not much to boast of, they extend a long way backward. The water area of the Liverpool docks and basins is 5984 acres, with a linear quayside of 22 miles. The Birkenhead docks, including the great float of 120 acres, contain a water area of 180 acres, with a linear quayside of 8 miles. The system of floating docks was commenced by the corporation in 1708. With the advancing demands of commerce the docks were extended north and south. They constituted from the

ties: a public trust, the corporation never having derived any revenue from them, though the common council of the borough were the trustees, and in the first instance formed the committee of management. Gradually the dock ratifiers acquired influence, and were introduced into the governing body, and ultimately, by the Act of 1856, the corporation was entirely superseded. Under the present constitution, the management is vested in the Mersey Docks and Harbour Board, consisting of twenty-eight members, two of whom are nominated by the Board of Trade and the rest elected by the dock ratifiers, of whom a register is kept and annually revised. The affairs of the board are of considerable magnitude. The revenue is derived from tonnage rates on ships, dock rates on goods, dues on goods, with various minor sources of income. These amounted in the year ending July 1, 1881, to £1,226,497. The amount of debt outstanding is £16,284,861, for which a rate of interest averaging 4½ per cent. is paid.

Down to 1843 the docks were confined to the Liverpool side of the Mersey. Several attempts were made to establish docks in Cheshire had been frustrated by the Liverpool corporation, who bought up the land and kept it in their own hands. In 1848 a scheme was privately conceived for the construction of docks at Birkenhead. Plans were prepared by Mr. Rendel, C.E., the money subscribed, and arrangements made with the Admiralty. The corporation being kept in ignorance of the proceedings, the plan was then made by private individuals to purchase 300,000 square yards of land on the margin of an inlet called Walley Pool. The common council, which had been reformer in 1836, unaccountably fell into the snare, and in the ensuing session of parliament a rival scheme of docks for Birkenhead was brought out and passed. The great expectations which were entertained of their successful competition with Liverpool have been signally falsified. After a twelve years' struggle and litigation, the Birkenhead dock affairs had fallen into a hopeless state of insolvency, without any prospect of recovery, and in 1855 the docks were transferred to the corporation of Liverpool on payment to the bondholders of 13s. in the pound on their claims. Under the Act of 1855, settling the future constitution of the dock board, the Birkenhead docks were transferred to the Mersey Docks and Harbour Board. The result on the whole has been disastrous. The amount expended on the Birkenhead docks does not exceed 100,000,000, but the returns for this immense outlay do little more than defray the working expenses, the difference having to be made up from the revenue on the Liverpool side, so that, in consequence of this unfortunate rivalry, the shipping frequenting the port is taxed to the amount of £370,000 per annum, which other wise might have been expended on other mercantile vessels of 120 tons, though it contributes little to the revenue, is valuable as a depot for ships lying up, so as not to interfere with the working docks. In addition to the floating docks, there are in Liverpool eighteen graving docks and three in Birkenhead, and two graving on the Liverpool side.

The great landing stage of Liverpool is unique in its dimensions and utility. It was originally constructed in 1857, from the plans of Mr. J. Cubitt, and greatly enlarged and extended in 1874, making the entire cost £278,000. The grand fabric had just been completed, and was waiting to be inaugurated by the Duke of Edinburgh, when on the 28th July 1874 it accidentally caught fire, and the timber being impregnated with kerosene, the flames spread with unexampled rapidity, and in a few hours the whole was destroyed. It was again constructed with improvements. Its length is 2668 feet, or about seven of a mile, and its breadth 80 feet. It is supported on floating pontoons rising and falling with the tide, connected with the quay by seven bridges, besides a floating bridge for heavy traffic 550 feet in length. The southern half is devoted to the traffic of the Mersey ferries, of which there are eight—New Brighton, Egremont, Seacombe, Birkenhead, Thunders, Rock Ferry, New Ferry, and Eastham. The northern half is used for sea-going steamers, and for the tenders of the great "liners." The warehouses for storing produce form a very prominent feature in the commercial part of the city. Down to 1841 these were entirely in private hands, distributed as chance might direct, but in that year a determined effort was made to construct docks with warehouses around on the margin of the quays. This met with considerable opposition from those interested, and led to a municipal revolution, but the project was ultimately carried out in the construction of the Albert dock and warehouses, which were opened by Prince Albert in 1845. Other docks since constructed have been similarly surrounded. The Albert warehouses form an immense area of land standing between the dock and the river, impeding from their huge dimensions, but otherwise the very incarnation of bad ignominy.

Grain warehouses on a large scale have been constructed by the dock board both at Liverpool and Birkenhead. The machinery for elevating, distributing, drying, and discharging is of the most complete and thorough kind. The total amount received from the warehouses in the year 1880-81 was £242,384.

History.—There are no archaeological difficulties attending the origin of the town, which is clearly defined by documentary evidence. The part of the country in which Liverpool is situated was not very

distinguished in the earlier periods of English history. No Roman remains have been discovered within a considerable distance. Under the Saxons the site formed part of the kingdom or province of Deira, the river Mersey (Mersa-sea) forming the boundary between the eighth century colonies of Northumbria and Mercia. During the Danish invasions of the Mersey, as is indicated by the names of the villages and townships in the district. After the Conquest, the site of Liverpool formed part of the fief (inter Ripam et Merham) granted by the Conqueror to Roger de Poitou, one of the great family of Magna comery. After various forfeitures and receipts from the crown, it was ultimately handed over by Henry II. to Warne, the keeper of the castle and prison of Lancaster. In a deed executed by King John, then earl of Mortuagne, about 1190, confirming the grant to his then other manors to Henry Fitzwarne, son of the former grantee, the name of *Liverpool* first occurs.

The name is split in a variety of ways, and much ingenuity has been exercised in the endeavour to explain its etymology. Probably the most plausible is the derivation from Cymric *Llyfyr-pool*, "the expanse of the pool," or "the pool of the confinement," which exactly expresses the peculiarity of the original site. It is, however, open to the objection that the Welsh language had died out in the locality long before Liverpool was founded.

The immediate origin of Liverpool was owing to the following circumstances. After the partial conquest of Ireland by Strongbow, earl of Pembroke, under Henry II., the principal ports of communication were Bristol for the west and Chester for the east. The gradual silting up of the river Dee soon so obstructed the navigation as to render Chester a very unsuitable place of embarkation. A quay was then constructed at Shotwick, about 8 miles below Chester, with a castle to protect it from the incursions of the neighbouring Welsh, but a better site was sought and soon found. Into the shallow waters of the Mersey, a small stream, fed by a peat moss on the elevated land to the eastward, ran in an oblique direction from north-east to south-west, forming at its mouth an open pool or sea lake, of which many existed on both sides of the river. The triangular piece of land thus separated formed a moorland of red sandstone rock, rising in the centre about 50 feet above the sea-level, sloping on three sides to the water. The pool was admirably adapted as a harbour for the vessels of that period, being well protected, and the tide rising from 15 to 21 feet. King John repurchased the manor from Henry Fitzwarne, giving him another in exchange, and here he erected a castle of great utility. The gradual plan of round bastions and bastionary walls, with an inner bailli and buildings. He also founded a town by the erection of burgage tenements, one hundred and sixty-eight in number, and in 1207 he issued the following letter patent or charter:—

Carta Regis Johannis.

Pro omnibus et singulis burgis apud Liverpoli infra viceriam, et Scitis quod concessimus omnibus qui burgagia apud Liverpoli cepit nosse liberos omnes libertates et liberos consuetudines in de Liverpoli quos aliqui habet burgages super nosse habet in terra nostra. Et nos vobis mandamus quod secure et in pace nostra sine ulla vendita ad burgagia nostra recipiatis ad hospitales. Et in iudicio testemur nos litteras nostras vobis velle transmittimus. Teste Simon de Patishill apud Winton xxviii die Aug anno regni nostri nono.

Charter of King John.

"The king to all who may be willing to have burgages at the town of Liverpool, &c. Know ye that we have granted to all who shall take burgages at Liverpool that they shall have all liberties and free customs in the town of Liverpool which any free borough on the sea hath in our land. And we command you that securely and in our peace you may come thence to receive our inhabitant burgages. And in testimony hereof we transmit to you these our letters patent. Witness, Simon de Patishill, at Winchester, the 28th day of August, in the ninth year of our said king's reign."

From the Patent Rolls and the sheriff's accounts we learn that considerable use was made of Liverpool in the reign of John for shipping stores and reinforcements to Ireland and Wales. In 1216 the town was garrisoned for the king during the rising which took place after the granting of the Great Charter.

In 1259 a charter of incorporation was granted by Henry III., authorizing the formation of a merchants' guild, with a house and other liberties and free customs, with sea and soil, toll and thane, &c., and freedom from toll in all the other seaports. Charters were subsequently granted by successive monarchs down to the reign of William and Mary, which last was the last charter of incorporation of the Municipal Reform Act (1835). In 1580 when the new diocese of Liverpool was created, the borough was transformed into a city by royal charter.

The crown revenues from the burgage rents and the royal customs were leased in fee-farm from time to time, sometimes to the corporation, at other times to private persons. The first lease was from Henry III. in 1250, at £10 per annum. In the same year the borough with all its appurtenances was bestowed, with other lands, on Ranulf, earl of Chester. During the subsequent two centuries the fee was repeatedly forfeited and regranted, until it finally passed into the hands of John of Gaunt, duke of Lancaster, and from the accession of his son Henry IV. it merged in the crown. In 1628 Charles I., in great straits for means which were refused by parliament, offered for sale about a thousand manors among which Liverpool was included. The corporation

lege, Oxford, where after a career of special distinction he graduated M.A. in 1753. Almost immediately on entering parliament as member for Cokeremouth in 1761, he was appointed under-secretary of state under Lord Bute, and, as he soon shared equally with that nobleman the favour of the king, his political advancement was rapid and uninterrupted while the friends of the king remained in office. By Grenville he was in 1763 appointed secretary of state; in the Grafton administration he, in 1766, obtained a seat at the Admiralty Board; and from 1778 till the close of Lord North's ministry he was secretary at war. On the accession of Pitt to power in 1784, he became president of the Board of Trade, retaining office till Pitt's resignation in 1801. Besides direct political power he also enjoyed a large share both of substantial and honorary political rewards. In 1773 he became member of the privy council, and obtained the vice-treasurership of Ireland, which he afterwards exchanged for the clerkship of the pells; and from 1786 to 1802 he was chancellor of the duchy of Lancaster. In 1786 he was created Baron Hawkesbury, and ten years afterwards earl of Liverpool. He died 17th December 1808. Lord Liverpool was generally believed to be the chief political adviser of George III. His prudence, practical talents, and knowledge of the details both of home and foreign politics rendered him a specially safe and useful member of a cabinet.

He was the author of several political works, which display industry and discrimination, but, with the exception of his well-known *Treatise on the Coins of the Realm*, 1805, are without striking merits. His other writings are—*National and Constitutional Force in England*, 1756; *Treatise between Great Britain and other Powers*, 1848-1783, 3 vols., 1785; *The Conduct of Great Britain in respect to Neutral Nations*, 1785, 3 vols., 1801.

LIVERPOOL, ROBERT BAYNES JENKINSON, SECOND EARL OF (1770-1828), son of the above by his first wife Amelia, daughter of Mr Watts, governor of Bengal, was born June 7, 1770. He was educated at Charterhouse and at Christ Church, Oxford, where he had Canning, afterwards his close political associate, for a contemporary. In 1791 he entered parliament as member for Rye, but he first held office in 1801 as foreign secretary in Addington's administration, when he conducted the negotiations for the abortive treaty of Amiens. On the accession of Pitt to power in 1804, he obtained the home office, and till his elevation to the House of Peers he acted as leader of the party in the House of Commons. He declined the premiership on the death of Pitt in 1806, and remained out of office till the accession of Perceval in 1809, when he again became home secretary. After the assassination of Perceval in 1812 he became prime minister, and retained office till compelled in February 1827 to resign by the illness (paralysis) which terminated his life, 4th December 1828. The political career of Lord Liverpool was entirely of a negative character so far as legislation was concerned; the only principle which regulated his statesmanship was persistent opposition to every kind of change, especially in the direction of increased religious or political liberty. From the beginning he strongly resisted Catholic emancipation, and he was also prominent in delaying the emancipation of the slaves. The energy of Castlereagh and Canning secured the outward success of the foreign policy of the cabinet, but in his home policy he was always unfortunate and retrograde. The Pains and Penalties Bill against Queen Caroline greatly increased his unpopularity, first originated by the severe measures of repression employed to quell the general distress, which had been created by undue taxation and was aggravated by blind adherence to protection. Though, therefore, actuated throughout by an honesty beyond all question, and though always commanding the sincere respect of his opponents by his dignified and considerate bearing, Lord Liverpool was destitute of wide and genial

sympathies, and of true political insight, and his resignation of office was followed almost immediately by the complete and permanent reversal of his domestic policy.

LIVERWORTS. The Liverworts or *Hepatice* constitute a group of the higher *Cryptogamia*, allied to the mosses. Their shoots are either *thalloid*, in some genera (*Marchantia*) highly differentiated in structure, in others (*Anthoceros*) of simple homogeneous texture, with an upper and lower surface, the latter fixed to the ground by capillary rootlets, and generally margined with minute scales; or they are *foliose*, the central stem bearing on each side a row of leaves, consisting of one series of cells invested with a structureless epidermis, and destitute of nerves, such as prevail in the leaves of mosses. Frequently on the inferior aspect a third row of leaf-like scales is found, differing from the former, and known as stipules, bracteoles, or amphigastria. Hence the shoots, although typically trifloral, often appear bilateral. The reproductive organs of the *Hepatice* are of two kinds—sexual and asexual.

I. The sexual germs of the mosses and *Hepatice* were first described by Hedwig just one hundred years ago (1782). They consist, as in the higher plants, of germ-cells and sperm-cells. As the fronds approach maturity the terminal leaves become modified so as to form an involucre, within which a special covering appears, the coleole or perianth, surrounding the pistillidia; this is tubular, conical, or compressed in form, with the mouth plicate and generally dentate.

On section of the coleole a number of minute flask-shaped bodies are found, attached to the apex of the stem, which have been named archigonia or pistillidia. After fertilization one of these enlarges, active cell formation proceeding from the central cell at the base, within which appears the germ-cell, which in time becomes the capsule, the ultimate contents producing spores arranged in fours, and elongated cells bearing within spiral filaments (elaters). Until the maturity of the spores, the sporangium remains at the base of the coleole, but at length the outer coat (calyptra) ruptures near the summit, and by the rapid evolution of the cells of the fruit-stalk (seta) the capsule is borne upwards. At this stage, which is of brief duration, the fronds look as if dotted with black-headed pins on white stalks. Released from pressure, the hygrometric action of the elater soon ruptures the wall of the capsule, which divides, in the majority of species, into four valves, and the spores are scattered around.

The antheridia are sometimes found imbedded in crypts within the substance of the thallus (*Riccia*), or in special receptacles either sessile or raised above the surface of the same (*Marchantia*). In the foliose *Hepatice* they are usually seated in the axils of modified leaves (perigonia), sometimes appearing beneath the fertile involucre (monocleous), or on special branches of the same plant (paracleous), or they occur on separate plants (dioecious). The antheridia are much smaller than the capsules, spheroidal or ovoid in form, and seated on a short footstalk. They are invested with a single coat of tubular cells. Before maturity they are greenish, but when ripe their colour turns to yellow. On pressure they rupture irregularly, and allow the escape of crowds of lenticular cells, which revolve actively under the microscope until the ciliated phytozoa within them are released.

The phytozoa of mosses were first figured by Unger (1834), who described them as consisting of a thick body, and a thin thread-like prolongation, which goes in advance when the body is in motion, and is spiral in form. Thuret has since shown that the so-called "tail" bears two long oscillating cilia. Hofmeister first observed the formation of the free germinative vesicle within the basal cell of the pistillidium as the direct result of fertilization.

II. *Asexual Germs*.—Beyond the true fructification, in the majority of *Hepaticæ*, certain bodies are met with, which are known as gemmæ, but which differ from each other in complexity and significance.

(1) In some *Marchantia* basket-like or crenate receptacles are found, containing lenticular bodies, which, under favourable conditions, will produce new fronds.

(2) On the borders of the leaves, especially near the apex of the shoots, proliferation from the ordinary cellular tissue is met with in most *Hepaticæ*, in the form of detached cells or tufts of such cells. These are generally described as gemmæ, but resemble more closely the *gonocidia* of lichens, and probably aid in the diffusion of dioecious species, which from the absence of ♂ or ♀ plants would otherwise become extinct.

(3) Another process has been ascribed to gemmation, but has been more happily named by Dr A. Braun *rejuvenescens* (*Verjüngung*). In decayed or apparently withered fronds, certain cells, after a period of rest, assume new activity and multiply so as to give rise to new individuals (*Antloeros*, *Riccia*, &c.).

Distinction between Hepaticæ and Musci.—There is scarcely a character in the definition of *Hepaticæ* which might not refer to some genus of mosses, although the definition as a whole may be sufficiently distinctive, and practically there is no difficulty in distinguishing one from the other.

In *Musci* the urn-case or capsule generally opens by means of a lid, and the mouth is surrounded by a peristome divided into four, eight, or more teeth. A columella is nearly always present, and the spore ripens in a sac between the former and the walls of the capsule. From the early elongation of the fruit rudiment, the calyptra is ruptured at an earlier stage, the upper part investing the urn-case like a cap, during the development of the spores, the lower remnant remains at the base of the seta (which, as well as the capsule, is composed of more lignous texture than in *Hepaticæ*) as the vaguella. The spore gives rise to a coniferous protuberance often extensively branched, and from this the buds arise. The leaves are imbricated on all sides of the stem, and the phylloaxis is usually 3, 4, or 5. The leaves are frequently strengthened by a midrib, and the rootlets are divided by numerous septa.

Edaphite.—The *Hepaticæ* are common in bogs, and form a relatively important average of the alpine vegetation, being abundant in moist equable and insular places, e.g., Ireland, Scotland, New Zealand. They are also met with in more tropical zones, such as South America, India, Java, and the West Indies.

Classification.

I. *Marchantiaceæ*.—Fronds thalloid, prostrate, furcate, epidermis pierced with numerous stomata, inner section areolate, occupied by green gemmal cells, lower surface simply cellular, emitting long rootlets, papillæ within.

(a) *Marchantia*.—Capsules aggregate on a stalked receptacle e.g., *Marchantia*, *Aspidella*, *Regetella*, *Dumortiera*, *Limnoria*, &c.

(b) *Tarponia*.—*Anthridia* immersed; involucre like a split pea; capsule nearly sessile, below the apex.

(c) *Levier*.—*Anthridia* and *pidellidia* immersed, the latter emitting the spores by the decay of the walls, spores without elaters: e.g., *Riccia*, *Ricciella*, &c.

II. *Jungmanniaceæ*.—Capsule solitary terminal on the primary shoots or on short lateral ones, splitting into four valves.

* *Filices*

(a) Leaves subcircular: e.g., *Jungmannia*, *Scoparia*, *Lophocolea*, &c.

(b) Leaves subovate: e.g., *Lijemna*, *Prullantia*, *Schiema*, *Lepidozia*, &c.

* *Frondosæ*: e.g., *Folia*, *Blasia*, *Petalophyllum*, &c.

III. *Anthocerotæ*.—Capsule horn or pod-like, opening by one or two valves, columella central, spores intermingled with deformed elaters: e.g., *Anthoceros*, *Monoecia*.

Use.—At the present time the *Hepaticæ* are of little practical use to man. In the dark ages of medicine, when the doctrine of "signatures" was in fashion, the strongly-marked epidermic cells were supposed to resemble the structure of the liver, and the species were esteemed "a sovran remedy" in liver complaints. The *Hepaticæ fontana* (*Marchantia polymorpha*) of Casper Baubine, which grows near springs, walls, and watery places, very low, almost like a moss, and puts out flowers about June, not unlike *stare*. It is wonderfully commended by Schroder, in those disorders of the liver which arise from too much heat (*English Dispensary*, 1788). A few species possess a pungent, bitter taste (*Porolia*) resembling that of *Sedum rosea*. Many also evolve a rank odour, observable in the woods

and fields after rain, and incorrectly referred to the smell of moist earth.

Beyond the beauty of tint and outline, which light up many a dreary ravine, they supply abundant material for the microscope, enabling us by the translucency of thams, and their easy preservation, so long as moisture is supplied, to study cell and leaf-structure, and the wonders of reproduction, as no other class will do.

Lastly, many fern-growers have of late included the *Hepaticæ* and *Musci* in their lists of favourites, the variety adding immeasurably to the interest of their collections. Most of the species are readily cultivated in a cold frame or fernery, the atmosphere of which must be kept moist and equable. In the renowned ferneries of Mr. Backhouse of York, A. Stansfeld of Tordrorden, and the Glanville Gardens, Dublin, species have long been cultivated, many foreign to the climate, and introduced with foreign plants. (B. C.)

LIVINGSTON, EDWARD (1764-1836). American jurist and statesman, was born in Clermont, Columbia county, New York, May 26, 1764. He was a great-grandson of Robert Livingston, the first possessor under royal patent of "Livingston Manor," a tract of land on the Hudson, comprising the greater part of the present counties of Dutchess and Columbia. Having graduated at Princeton in 1781, he began to practise law in New York city, and rapidly rose to distinction as an advocate. He was a member of congress during 1794-98, and in 1801 was appointed United States district attorney for the State of New York, and while retaining that position was also elected mayor of New York city, then an office of high dignity and emolument. In the summer of 1803 New York was visited with a violent epidemic of yellow fever, during which Livingston displayed great courage and energy in his endeavours to prevent the spread of the disease, and to relieve the widespread distress. He suffered an attack of the fever in its most violent form, during which the people of the city gave many proofs of their attachment and anxiety. He recovered to find his private affairs, which he had neglected, in some confusion, and he was at the same time deeply indebted to the Government for public funds which had been lost through the mismanagement of a confidential clerk. Livingston at once surrendered all his property, and, having resigned his office, removed to Louisiana, which had then just been ceded by France to the United States. He soon acquired a large law practice in New Orleans, and repaid the Government in full. Almost immediately upon his arrival in Louisiana he was appointed by the legislature to prepare a provisional code of judicial procedure, which was continued in force from 1806 to 1826. During the short war with England in 1814-15, Livingston was active in rousing the mixed population of New Orleans to resistance, and acted as adviser and aide-de-camp to Jackson. In 1821, by appointment of the legislature, Livingston began the preparation of a new code of criminal law and procedure, since widely known in Europe and America as the "Livingston Code." It was prepared in both French and English, as required by the necessities of practice in Louisiana, and, though substantially completed in 1824, and in greater part then adopted by the State, it was not printed entire until 1833. It was at once reprinted in England, France, and Germany, attracting wide interest and praise from the most distinguished sources by its remarkable simplicity and vigour, and more especially by reason of its philanthropic provisions, which have noticeably influenced; the penal legislation of several countries. Livingston was a member of congress during 1829-33, was afterwards senator, and for two years secretary of state under President Jackson. From 1833 to 1835 he was minister plenipotentiary to France, and conducted with success negotiations of considerable difficulty and importance. He died May 23, 1836.

See *Livingston's Life* by C. H. Hunt (New York, 1864), and his complete *Works* (2 vols., 1877).

LIVINGSTON, ROBERT R (1746-1813), American statesman, brother of Edward Livingston noticed above, was born at New York, November 27, 1746. He graduated at King's College, New York, at the age of nineteen, became a practitioner of law, and in 1773, recorder of the city, but was soon displaced by loyalist influence because of his sympathies with the revolution. In 1776 he was a member of the committee of congress which drew up the Declaration of Independence, and in 1777 was a prominent member of the convention at Kingston, which framed the first constitution of New York. Upon the adoption of that instrument in the same year he became the first chancellor of the State, which office he held until 1801, whence he is best known as "Chancellor" Livingston. He administered the oath of office to Washington at his first inauguration to the presidency in New York, April 30, 1789. In 1801 he was appointed by President Jackson as minister to France, and in 1803 effected in behalf of his Government the purchase from France of the vast territory then known as Louisiana, comprising the entire territory between the Mississippi and the Rocky Mountains, from the Spanish to the British possessions. This was, perhaps, the most important transfer of territory by purchase ever made, but none of those who participated in it realized its importance. Napoleon's agent obtained ten million francs more than he had been instructed to accept for the cession, and Jefferson and Livingston were at the time bitterly censured for rashly concluding so useless a purchase. In 1804 Livingston withdrew from public life, and after spending a year in travel in Europe, returned to New York, where he occupied his remaining years in promoting various improvements in agriculture. He also assisted Fulton in his invention of the steamboat. He died in February 1813.

LIVINGSTONE, DAVID (1813-1878), missionary and explorer, was born on March 19, 1813, at the village of Dlantry Works, in Lanarkshire, Scotland. David was the second child of his parents Neil Livingston (for so he spelled his name, as did his son for many years) and Agnes Hunter. His parents were poor and self-respecting, typical examples of all that is best among the humbler families of Scotland. At the age of ten years David left the village school for the neighbouring cotton-mill, and by strenuous efforts he qualified himself at the age of twenty-three to undertake a college curriculum. He attended for two sessions the medical and the Greek classes in Anderson's College, and also a theological class. In September 1838 he went up to London, and was accepted by the London Missionary Society as a candidate. During the next two years he resided mostly in London, diligently attending medical and science classes, and spending part of his time with the Rev. Mr. Cecil at Ougar in Essex, studying theology and learning to preach. He took his medical degree in the Faculty of Physicians and Surgeons in Glasgow in November 1840. Livingston had from the first set his heart on China, and it was a great disappointment to him that the Society finally decided to send him to Africa. To an exterior in these early years somewhat heavy and uncouth, he united a manner which, by universal testimony, was irresistibly winning, with a fund of genuine but simple humour and fun that would break out on the most unlikely occasions, and in after years enabled him to overcome difficulties and mellow refractory chiefs when all other methods failed.

Livingstone sailed from England on December 8, 1840. From Algoa Bay he made direct for Kuruman, the mission station, 700 miles north, established by Hamilton and Moffat thirty years before, and there he arrived on July 31, 1841. The next two years Livingston spent in travelling about the country to the northwards, in search of a suitable outpost for settlement. During these two

years he had already become convinced that the success of the white missionary in a field like Africa is not to be reckoned by the tale of doubtful conversions he can send home each year,—that the proper work for such men was that of pioneering, opening up and starting new ground, leaving native agents to work it out in detail. The whole of his subsequent career was a development of this idea. He selected the valley of Mabotsa, on one of the sources of the Limpopo river, 200 miles north-east of Kuruman, as his first station. It was shortly after his settlement here that he was attacked by a lion which crushed his left arm, and nearly put an end to his career. The arm was imperfectly set, and it was a source of trouble to him at times throughout his life, and was the means of identifying his body after his death. To a house, mainly built by himself at Mabotsa, Livingston in 1844 brought home his wife, Mary Moffat, the daughter of Moffat of Kuruman. Here he laboured till 1846, when he removed to Chocuanne, 40 miles further north, the chief place of the Bakwain tribe under Sechele. In 1847 he again removed to Kolobeng, about 40 miles westwards, the whole tribe following their missionary. With the help of and in the company of two English sportsmen, Mr. Oswell and Mr. Murray, he was able to undertake a journey of great importance to Lake Ngami, which had never yet been seen by a white man. Crossing the Kalahari Desert, of which Livingston gave the first detailed account, they reached the lake on August 1, 1849. In April next year he made an attempt to reach Sebitane, who lived 200 miles beyond the lake, this time in company with his wife and children, but again got no further than the lake, as the children were seized with fever. A year later, April 1851, Livingston, again accompanied by his family and Mr. Oswell, set out, this time with the intention of settling among the Makololo for a period. At last he succeeded, and reached the Chobe, a southern tributary of the Zambesi, and in the end of June discovered the Zambesi itself at the town of Sesheke. Leaving the Chobe on August 13, the party reached Capetown in April 1852. Livingston may now be said to have completed the first period of his career in Africa, the period in which the work of the missionary had the greatest prominence. Henceforth he appears more in the character of an explorer, but it must be remembered that he regarded himself to the last as a pioneer missionary, whose work was to open up the country to others.

Having, with a sad heart, seen his family off to England, Livingston left the Cape on June 8, 1852, and reached Linyanti, the capital of the Makololo, on the Chobe, on May 23, 1853, received in royal style by Sekeletu, and welcomed by all the people. His first object in this journey was to seek for some healthy high land in which to plant a station. Ascending the Zambesi, he, however, found no place free from the destructive tsetse insect, and therefore resolved to discover a route to the interior from either the west or east coast. To accompany Livingston in his hazardous undertaking twenty-seven men were selected from the various tribes under Sekeletu, partly with a view to open up a trade route between their own country and the coast. The start was made from Linyanti on November 11, 1853, and, by ascending the Leeba, Lake Dilolo was reached on February 20, 1854. On April 4 the Coango was crossed, and on May 31 the town of Loanda was entered, much to the joy of the men,—their leader, however, being all but dead from fever, semi-starvation, and dysentery. Livingston speaks in the warmest terms of the generosity of the Portuguese merchants and officials. From Loanda Livingston sent his astronomical observations to Madagat at the Cape, and an account of his journey to the Royal Geographical Society, which in May 1855 awarded him its highest honour, its gold medal.

Loanda was left on September 20, 1854, but Livingstone lingered long about the Portuguese settlements. Making a slight detour to the north to Chibango, the party reached Lake Dilolo on June 13. Here Livingstone made a careful study of the watershed of the country in what is perhaps the most complicated river system in the world. He "now for the first time apprehended the true form of the river systems and the continent," and the conclusions he came to have been essentially confirmed by subsequent observations. The return journey from Lake Dilolo was by the same route as that by which the party came. Their reception all along the Barotse valley was an ovation, and Linyanti was reached in the beginning of September.

For Livingstone's purposes the route to the west was unavailable, and he decided to follow the Zambezi to its mouth. With a numerous following, he left Linyanti on November 8, 1855. A fortnight afterwards he made the great discovery with which, in popular imagination, his name is more intimately associated than with anything else he did,—the famous "Victoria" falls of the Zambezi, which, after a second examination in his subsequent journey, he concluded to be due to an immense fissure or fault right across the bed of the river, which was one means of draining off the waters of the great lake that he supposed must have at one time occupied the centre of the continent. He had already formed a true idea of the configuration of the continent as a great hollow or basin-shaped plateau, surrounded by a ring of mountains. Livingstone reached the Portuguese settlement of Tette on March 2, 1856, in a very emaciated condition, and after six weeks, left his men well cared for, and proceeded to Kilimane, where he arrived on May 20, thus having completed in two years and six months one of the most remarkable and fruitful journeys on record. The results in geography and in natural science in all its departments were abundant and accurate; his observations necessitated a reconstruction of the map of central Africa. Men of the highest eminence in all departments of science testified to the high value of Livingstone's work. In later years, it is true, the Portuguese, embittered by his unsparing denunciations of their traffic in slaves, attempted to depreciate his work, and to maintain that much of it had already been done by Portuguese explorers. When Livingstone began his work in Africa it was virtually a blank from Karuman to Timbuctoo, and nothing but envy or ignorance can throw any doubt on the originality of his discoveries.

On December 12 he arrived in England, after an absence of sixteen years, and met everywhere with the welcome of a hero. He told his story in his *Missionary Travels and Researches in South Africa* (1857) with straightforward simplicity, and with no effort after literary style, and no apparent consciousness that he had done anything extraordinary. Its publication brought what he would have considered a competency had he felt himself at liberty to settle down for life. In 1857 he severed his connexion with the London Missionary Society, with whom, however, he always remained on the best of terms, and in February 1858 he accepted the appointment of "Her Majesty's consul at Kilimane for the eastern coast and the independent districts in the interior, and commander of an expedition for exploring eastern and central Africa."

The Zambezi expedition, of which Livingstone thus became commander, sailed from Liverpool in H.M.S. "Pearl" on March 10, 1858, and reached the mouth of the Zambezi on May 14, and the party ascended the river from the Kongone mouth in a steam launch, the "Ma-Robert," reaching Tette on September 8. The remainder of the year was spent in examining the river above Tette, and especially the Kobabasa rapids. Most of the year 1859 was spent in the exploration of the river Shire and Lake

Nyassa, which was discovered in September; and much of the year 1860 was spent by Livingstone in fulfilling his promise to take such of the Makalolo home as failed to go. In January of next year arrived Bishop Mackenzie and a party of missionaries sent out by the Universities Mission to establish a station on the upper Shire.

After exploring the river Korrums for 30 miles in his new vessel the "Pioneer," Livingstone and the missionaries proceeded up the Shire to Chibias; there they found the slave trade rampant, desolating the country and paralysing all effort. On July 15 Livingstone, accompanied by several native carriers, started to show the bishop the country. Several bands of slaves whom they met were liberated, and after seeing the missionary party settled in the highlands of Magomero to the south of Lake Shirwa, Livingstone spent from August to November in exploring Lake Nyassa. While the boat sailed up the west side of the lake to near the north end, the explorer marched along the shore. He returned more resolved than ever to do his utmost to rouse the civilized world to put down the desolating slave-trade. On January 30, 1862, at the Zambezi mouth, Livingstone welcomed his wife and the ladies of the mission, with whom were the sections of the "Lady Nyassa," a river steamer which Livingstone had had built at his own expense, absorbing most of the profits of his book, and for which he never got any allowance. When the mission ladies reached the mouth of the Euphrates of the Shire, they were stunned to hear of the death of the bishop and of Mr. Burrap. This was a sad blow to Livingstone, seeming to have rendered all his efforts to establish a mission futile. A still greater loss to him was that of his wife at Shupanga, on April 27, 1862.

The "Lady Nyassa" was taken to the Rovuma. Up this river Livingstone managed to stave 156 miles, but further progress was arrested by rocks. Returning to the Zambezi in the beginning of 1863, he found that the desolation caused by the slave trade was more horrible and widespread than ever. It was clear that the Portuguese officials were themselves at the bottom of the traffic. Kirk and Charles Livingstone being compelled to return to England on account of their health, the doctor resolved once more to visit the lake, and proceeded some distance up the west side and then north-west as far as the watershed that separates the Loangwa from the rivers that run into the lake. Meanwhile a letter was received from Earl Russell recalling the expedition by the end of the year. In the end of April 1864 Livingstone reached Zanzibar in the "Lady Nyassa," and on the 30th he set out with nine natives and four Europeans for Bombay, which was reached after an adventurous voyage of a month, and on July 23 Livingstone arrived in England. He was naturally disappointed with the results of this expedition, all its leading objects being thwarted through no blame of his. For the unfortunate disagreements which occurred, and for which he was blamed in some quarters, he must be held acquitted, as he was by the authorities at home; though it is not necessary to maintain that Livingstone was exempt from the trying effects on the temper of African fever, or from the intolerance of lukewarmness which belongs to all exceptionally strong natures. Still the results at the time, and especially those of the future, were great. The geographical results, though not in extent to be compared to those of his first and his final expeditions, were of high importance, as were those in various departments of science. Details will be found in his *Narrative of an Expedition to the Zambezi and its Tributaries*, published in 1865.

By Murdison and his other staunch friends Livingstone was as warmly welcomed as ever. When Murdison proposed to him that he should go out again, although he seems to have had a desire to spend the remainder of his

days at home, the prospect was too tempting to be rejected. He was appointed H.M. consul to central Africa without a salary, and Government contributed only £500 to the expedition. The chief help came from private friends. During the latter part of the expedition Government granted him £1000, but that, when he learned of it, was devoted to his great undertaking. The Geographical Society contributed £500. The two main objects of the expedition were the suppression of slavery by means of civilizing influences, and the ascertainment of the watershed in the region between Nyassa and Tanganyika. At first Livingstone thought the Nile problem had been all but solved by Speke, Baker, and Burton, but the idea grew upon him that the Nile sources must be sought farther south, and his last journey became in the end a forlorn hope in search of the "fountains" of Herodotus. Leaving England in the middle of August 1855, via Bombay, Livingstone arrived at Zanzibar on January 28, 1856. He was landed at the mouth of the Rovuma on March 23, and started for the interior on April 4. His company consisted of thirteen sepoys, ten Johanna men, nine African boys from Nassick school, Bombay, and four boys from the Shire region, besides camels, buffaloes, mules, and donkeys. This imposing outfit soon melted away to four or five boys. Rounding the south end of Lake Nyassa, Livingstone struck in a north-north-west direction for the south end of Lake Tanganyika, over country much of which had not previously been explored. The Loangwa was crossed on December 15, and on Christmas day Livingstone lost his four goats, a loss which he felt very keenly, and the medicine chest was stolen in January 1856. Fever came upon him, and for a time was his almost constant companion; thus, with the fearful dysentery and dreadful ulcers and other ailments which subsequently attacked him, and which he had no medicine to counteract, no doubt took fatally on even his iron frame. The Chambeze was crossed on January 28, and the south end of Tanganyika reached March 31. Here, much to his vexation, he got into the company of Arab slave dealers, by whom his movements were hampered; but he succeeded in reaching Lake Moero. After visiting Lake Mofwa and the Luabala, which he believed was the upper part of the Nile, he, on July 18, discovered Lake Bangweolo. Proceeding up the west coast of Tanganyika, he reached Ujiji on March 14, 1859, "a ruckle of bones." Supplies had been forwarded to him at Ujiji, but had been knavishly made away with by those to whose care they had been entrusted. Livingstone recrossed Tanganyika in July, and through the country of the Manyema he tried in vain, for a whole year, to reach and cross the Luabala, baffled partly by the natives, partly by the slave hunters, and partly by his long illnesses. It was, indeed, not till March 29, 1871, that he succeeded in reaching the Luabala, at the town of Nyangwe, where he stayed four months, vainly trying to get a canoe to take him across. It was here that a party of Arab slaves, without warning or provocation, assembled one day when the market was busiest and commenced shooting down the poor women, hundreds being killed or drowned in trying to escape. Livingstone had "the impression that he was in hell," but was helpless, though his "first impulse was to pistol the murderers." The account of this scene which he sent home roused indignation in England to such a degree as to lead to determined and to a considerable extent successful efforts to get the sultan of Zanzibar to suppress the trade. In sickened disgust the weary traveller made his way back to Ujiji, which he reached on October 13. Five days after his arrival in Ujiji he was cheered and inspired with new life, and completely set up again, as he said, by the timely arrival of Mr H. M. Stanley, the richly laden almoner of Mr Gordon Bennett, of the *New York Herald*. Mr Stanley's residence

with Livingstone was almost the only bright episode of these last sad years. With Stanley Livingstone explored the north end of Tanganyika, and proved conclusively that the Luasia runs into and not out of it. In the end of the year the two started eastward with an ample supply of goods, and bade him farewell. Stanley left on March 15, 1872, and after Livingstone had waited wearily at Unyamwebe for five months, a troop of fifty-seven men and boys arrived, good and faithful fellows on the whole, selected by Stanley himself. Thus attended, he started on August 15 for Lake Bangweolo, proceeding along the east side of Tanganyika. His old enemy dysentery soon found him out. In January 1873 the party got among the endless spongy jungle on the east of Lake Bangweolo, Livingstone's object being to go round by the south and away west to find the "fountains." Vexatious delays took place, and the journey became one constant wade below, under an almost endless pour of rain from above. The doctor got worse and worse, but no idea of danger seems to have occurred to him. At last, in the middle of April, he had unwillingly to submit to be carried in a rude litter. On April 28 Chitambo's village on the Luabala, in Itala, on the south shore of the lake, was reached. The last entry in the journal is April 27:—"Knocked up quite, and remain—recover—sent to buy milk goats. We are on the banks of the Mollamo." On April 30 he with difficulty wound up his watch, and early on the morning of May 1 the boys found "the great master," as they called him, kneeling by the side of his bed, dead. His faithful men preserved the body in the sun as well as they could, and wrapping it carefully up, carried it and all his papers, instruments, and other things across Africa to Zanzibar. It was borne to England with all honour; and on April 18, 1874, was deposited in Westminster Abbey, amid tokens of mourning and admiration such as England accords only to her greatest sons. Government bore all the funeral expenses. His faithfully kept journals during these seven years' wanderings were published under the title of the *Last Journals of David Livingstone in Central Africa*, in 1874, edited by his old friend the Rev. Horace Waller.

In spite of his sufferings and the many compulsory delays, Livingstone's discoveries during these last years were both extensive and of prime importance as leading to a solution of African hydrography. No single African explorer has ever done so much for African geography as Livingstone during his thirty years' work. His travels covered one-third of the continent, extending from the Cape to near the equator, and from the Atlantic to the Indian Ocean. Livingstone was no hurried traveller, he did his journeying leisurely, carefully observing and recording all that was worthy of note, with rare geographical instinct and the eye of a trained scientific observer, studying the ways of the people, eating their food, living in their huts, and sympathizing with their joys and sorrows. It will be long till the tradition of his sojourn dies out among the native tribes, who almost, without exception, treated Livingstone as a superior being; his treatment of them was always tender, gentle, and gentlemanly. But the direct gains to geography and science are perhaps not the greatest results of Livingstone's journeys. He conceived, developed, and carried out to success a noble and many-sided purpose, with an unflinching and self-sacrificing energy and courage that entitle him to take rank among the great and strong who single-handed have been able materially to influence human progress, and the advancement of knowledge. His example and his death have acted like an inspiration, filling Africa with an army of explorers and missionaries, and raising in Europe so powerful a feeling against the slave trade that it may be considered as having received its death-blow. Personally Livingstone was a pure and tender-hearted man,

full of humanity and sympathy, simple-minded as a child. The motto of his life was the advice he gave to some school children in Scotland,—"Fear God, and work hard."

See, besides his own narrative and Dr Blaikie's *Life*, the publications of the London Missionary Society from 1840, the *Proceedings of the Royal Geographical Society*, the despatches to the Foreign Office sent home by Livingstone during his last two expeditions, and Mr H M Stanley's *How I Found Livingstone*. (J. S. K.)

LIVYUS ANDRONICUS occupies the position of the oldest among the recognized poets of Rome. He determined the course which Roman literature followed for more than a century after his time. The imitation of Greek comedy, tragedy, and epic poetry, which produced great results in the hands of Nævius, Plautus, Ennius, and their successors, received its first impulse from him. To judge, however, by the very insignificant remains of his writings, and by the testimonies of Cicero and Horace to his merits, he can have had no preclusion either to original genius or to artistic accomplishment. His real claim to distinction was that he was the first great schoolmaster of the Roman people, and the first acknowledged medium through which the genius of Greece acted on the Roman mind, and found for itself a rude expression in the Latin language. His name, in which the Greek *Andronicus* is combined with the gentle name of one of the great Roman houses, while indicative of his own position as a manumitted slave, is also significant of the influences by which Roman literature was fostered,—viz., the culture of men who were either Greeks or "semi-Greeks" by birth and education, and the protection and favour afforded to them by the more enlightened members of the Roman aristocracy. He is supposed to have been a native of Tarentum, and to have been brought while still a boy, after the capture of that town in 272 B.C., as a slave to Rome. He lived in the household of a member of the *gens Livia*, probably of that branch of it to which M. Livius Salinator, the colleague of C. Claudius Nero in the year of the battle of the Metaurus, belonged. We learn from Suetonius that, like Ennius after him, he obtained his living by teaching Greek and Latin; and it was probably as a schoolbook, rather than as a work of literary pretension, that his translation of the *Odyssey* into Latin Saturnian verse was executed. This work was still used in schools when Horace was taught at Rome by the famous grammarian and disciplinarian Orbilius. From the few fragments of the translation that have been preserved it may be inferred that it was owing to the conservatism of educational methods, rather than to its fitness to impart to boys in the Ciceronian age instruction either in Greek literature or in the Latin language, that it enjoyed this distinction. But at the time when it appeared it must have satisfied a real want. In the wars with Pyrrhus and Tarentum the Romans had for the first time come into close contact with the Greeks; and during the First Punic War (from 261 to 241 B.C.), in which Sicily was the chief battleground of the combatants, this contact was much closer. The knowledge of Greek became essential to men in a high position, as a means of intercourse with Greeks; and at the same time the new ideas and new interests of Greek literature began to exercise something of that stimulating and refining power over the minds of the leading men which it exercised in a later generation over Scipio Africanus, T. Quintus Flaminius, M. Fulvius Nobilior, and others like them. But the presence of the Roman armies in southern Italy and Sicily must have accustomed many who had no means of obtaining a literary education to the representations of the Greek tragic and comic poets. Although the great creative age of the Athenian drama was passed, the passion for the representation of the old plays still continued, and was not confined to Athens. The number of theatres of which the remains are still seen in Sicily—as at Segesta, Syracuse, Catania,

Taormina—indicate that, in the island in which Epicharmus had produced his old Doric comedies, the representation of tragedy and comedy continued to be a most important element in the life of the people. But the Romans and Italians had an indigenous drama of their own, known by the name of *Satura*, which prepared them for the reception of the more regular Greek drama. The distinction between this *Satura* and the plays of Euripides or Menander was that it had no regular plot. This Latin drama first received from Livius Andronicus; but it did so at the cost of its originality. In the year 240, the year after the end of the First Punic War, he produced at Rome a translation of a Greek play (it is uncertain whether a comedy or tragedy), and this representation marks the beginning of Roman literature. In this translation he discarded the native Saturnian metre, and adopted the iambic, trochaic, and cretic metres, to which Latin more easily adapted itself than either to the hexameter or to the lyrical measures of a later time. He continued to produce plays for more than thirty years after this time. The titles of some of his tragedies are *Achilles*, *Agisthus*, *Equus Trojanus*, *Hermione*, *Tereus*,—all suggestive of subjects which were treated by the later tragic poets of Rome. The titles of some of his comedies are *Gladiolus*, *Ludus*, &c. In the year 207, when, if he was a captive after the taking of Tarentum, he must have been of a great age, he was appointed to compose the hymn of thanksgiving for the victory of the Metaurus. Another tribute of national recognition paid him was that, as a compliment to him, the "college" or "guild" of poets obtained a place of seating in the temple of Minerva on the Aventine.

A good account of his remains is to be found in Wordsworth's *Fragments and Specimens of Early Latin*. The fragments of his dramas are to be found in Ribbeck's *Fragmentum Latinorum Reliquiae* and *Compositum Latinorum Reliquiae* (W. Y. 8.)

LIVNY, a district town of Russia, in the government of Orel, 87 miles east-south-east of the chief town of the government, at the confluence of the rivers Lypevka and Sosna. It has railway connexion with the line between Orel and Gryn. The town is an important centre for trade in grain, hemp, tallow, skins, and cattle. A large amount of grain is purchased in the neighbouring governments, and the flour is sent to Moscow and the neighbouring towns, as well as to the Baltic ports. Hemp is sent to St Petersburg, and cattle to Moscow, or they are killed for the preparation of tallow. The 13,000 inhabitants of Livny find employment in trade and in the flour-mills, and hemp, tallow-candle, and oil works. The district of Livny is one of the most fertile and populous of central Russia, and is remarkable for its numerous large villages.

Livny was founded in 1596, at the junction of the three highways to Astrakhan, to Little Russia, and to the Caucasus, along which the Tartars usually made their incursions on Russian provinces. It was several times destroyed by Tartars during the 16th and 17th centuries. In the great internal wars of the first half of the 16th century, Livny was a centre where all kinds of discontented persons and murderers met. Its fort, or kreml, with thick earthen and wooden walls, existed until 1784.

LIVONIA, or LIVLAND (*Liflandia* of the Russians), one of the three Baltic provinces of Russia, is bounded by the Gulf of Riga on the W., Esthonia on the N., the governments of St Petersburg, Pskov, and Vitebsk on the E., and Courland on the S. A group of islands, situated at the entrance of the Gulf of Riga, of which Osel, Mohu, Runo, and Paternoster are the largest, belong to this government. It covers, with the islands, a surface of 18,160 square miles, but of this the part of Lake Peipus, or *Lochudskoye*, which belongs to it occupies 1090. Its surface is diversified by several plateaus, those of Iianhoff and of the Lvonian As having an average height of 700 feet, whilst several summits reach from 800 to 1000 feet or more (such as the Munna-Mägi, 1063 feet; Hailing-

kains, 1038 feet, Vella-Maggi, 946 feet, Tufolsberg, 847 feet). The edges of the plateaus are intersected by deep valleys, which give a hilly character to the country; the hilly tract between the Duna and its tributary the Līvianian Aa has received from its picturesque narrow valleys, covered with deep forests and numerous lakes, the name of "Wendish Switzerland." The plateau of Odenpa, watered by the tributaries of the Embach river, which flows for 93 miles from lake Wierz-yarvi into Lake Peips, occupies an area of 2880 square miles, and has an average height of 500 feet. More than a thousand lakes are scattered over Livonia, of which that of Wierz-yarvi, having a surface of 105 square miles (114 feet above sea-level), is the largest, marshes and peat-bogs occupy as much as one-tenth of the province. Of the very numerous rivers which water Livonia, only the Duna, which flows for 80 miles along its frontier, and the Embach are navigable.

The geological structure of Livonia has been elaborately examined. The Silurian formation which covers Esthonia, and much resembles the Norwegian Silurian, appears in the northern part of Livonia, the remainder of the province consisting of Devonian strata. The whole is covered with a night sheet of glacial deposits, sometimes 400 feet thick. The typical bottom moine, with boulders of all sizes up to 20 feet in diameter, brought from Finland, extends all over the country, reaching even to the summit of Munna-Maggi. Glacial fluviols, striae, and elongated troughs are met with everywhere, running mostly from north-west to south-east, as well as *æter*, which have the same direction and consist of moraine nucleus covered with stratified sands and clays; sand-downs cover large tracts on the shores of the Baltic. As in Esthonia, no traces of marine deposits are found higher than 100 or 150 feet above the present sea-level. The soil is not very fertile. Forests cover about two-fifths of the surface of this government, several of them having a diameter of 150 to 250 miles. The climate is rather severe. The mean temperatures are 43° Fahr. at Riga (winter, 23°; summer, 63°), and 42½° at Dorpat. The intensity and direction of winds are very variable; the average number of rainy and snowy days is one hundred and forty-six at Riga (rainfall 24½ inches); fogs are not uncommon.

The population of Livonia, which was but 621,600 in 1816, reached 1,000,876 in 1870, and is now about 1,121,000 in 1882. Though it is often described as a German province, only about 7 per cent of the population (84,120 in 1880) are Germans, the great bulk being *Ehsts* or *Esthians* (47 per cent) and *Letts* (41 per cent.). The Russians number about 36,000, Poles 5000, and Jews 7000. The Livonians, who have given their name to the country, and who formerly extended far east to Sobeg in the government of Vitbeak, have nearly all passed away; only a few thousands (2050 in 1868) inhabit the forests at the utmost extremity of the peninsula of Courland. Their native language, of Finnish origin, is rapidly disappearing, their present language being rather a *Lettsish*. Sjögren, in 1846, had much difficulty in making a grammar and dictionary of it from the mouths of old people. The *Ehsts* who greatly resemble the Finns of Tavastland, have maintained their ethnic features, their customs, national traditions, national songs and poetry, and their harmonious language. There is now a marked revival of national feeling, favoured by "Young Esthonia," together with a tendency towards a union with Finland. No less than eight political papers are published in the Esthonian language. The prevailing religion is the Lutheran (746,664 in 1868), about 80,000 *Ehsts* in Livonia and Esthonia, and 50,000 *Letts* (see LITHUANIA), as well as the Russians, belong to the Greek Church (150,874 in 1868); of the Russians, however, a considerable proportion are *raekomists* (nonconformists), who have migrated to the Baltic provinces in consequence of persecutions, their last number about 14,600, of whom 8000 are found in the neighbourhood of Riga. About 6000 are Catholics. The Germans belong to the nobility, or to the burger class in the towns.

The efforts of the German conquerors to Germanize the country have completely failed. The *Ehsts* and *Letts* openly display their traditional hatred against the invaders. The teaching in primary schools is carried on in Esthonian and Lettsish, German prevails in colleges and higher schools. The Russian Government has for

some time been labouring for "Russification" the Russian civil code was introduced in the Baltic provinces in 1885, and the use of Russian, instead of German, in official correspondence and in law courts was ordered in 1897, but not generally thought of as practising, the fact that the privileges given by the military law to those who have received primary education extend only to those who know Russian contributes to the extension of that language.

Nearly all the soil belongs to the nobility, the extent of peasants' estates being only 15 per cent. Serfdom was abolished in 1819, when the peasants received personal liberty, remaining, however, under the jurisdiction of their landlords, who maintained also the right to have a predominant influence in the nomination of ministers. Since 1849 the contribution in forced labour which the peasants were compelled to pay to landlords has been gradually, though imperfectly, commuted to a money payment, and the peasants have received the right to purchase their allotments. But, owing to later limitations of this law, as well as to the high price of allotments and to the establishment of a minimum size of 80 acres, the redemption of the land is going on very slowly. The class of peasant proprietors being restricted to a small number of healthy peasants, the great bulk have remained *Knochts*, that is, tenants at will; they are very miserable, and about one-fourth of them are continually wandering in search of work. They readily emigrate, even to such unfertile provinces as Novgorod and Vitbeak, and from time to time the emigration takes the shape of a mass movement, which the Government stops. The average size of landed estates is from 9500 to 11,000 acres, far above the general average for Russia. The estates of the nobility are generally as well cultivated as in western Europe, while the peasants' farms are mostly in a deplorable state. In 1877 21 4 per cent of the surface of Livonia was under crop, yielding 1,949,800 quarters of grain, and 1,849,300 measures of rye. There were at the same time 148,000 horses, 373,000 cattle, 312,000 sheep, and 150,000 pigs. The shores of the Baltic yield valuable fisheries. Manufactures are steadily increasing. The distilleries yield about 1,400,000 gallons of spirits, part of which is exported; the beer breweries (two hundred) produce ten worth about 850,000 roubles. There are woollen, cotton, and silk mills, saw, glass, and paper, glass, candle, tobacco, and machinery works—the chief manufacturing districts being Pernau and Riga. Livonia carries on a large export trade, especially through Riga and Pernau, in flax, linseed, hemp, grain, timber, and wooden ware; the Duna is of course the chief channel for the exports. During the last 10 years, however, Libau has entered into brisk competition with the more northern ports of Livonia. The imports, especially through Riga, are also most important, the custom-house of Livonia having had in 1881 an income of 6,000,000 silver roubles. The government is divided in eleven districts: Riga (104,500), Wolmar (32,800), Dorpat (32,800), Riga (12,500), Fellin (65,000), Arensburg in the island Oel (8150), Walk (3850), Fellin (2900), Werro (2050), Lemsal (1450), and Schloek (800). The capital of the government is Riga.

The first historical notices of Livonia are by Tacitus and Jordanes, but none of the time of Alexander the Great, found on the island of Oel, show that the coasts of the Baltic were at an early time in commercial relations with the civilized world. The chronicler Nestor mentions as inhabitants of the Baltic coast the Tchud, the Laves, the Narova, Leligals, Semigallians, and Koré. It is probably about the 9th century that was founded the first tributary to the Varjago-Russian states. As they reacquired their independence, Yaroslav I. undertook in 1093 a campaign against them, and founded Yornoff (Dorpat). The first Germans penetrated into Livonia in the 11th century, and in 1158 several Bremen merchants landed at the mouth of the Duna. In 1186 the emperors of the archbishop of Bremen began to preach the Christian religion among the *Ehsts* and *Letts*, and in 1200 the archbishop of Livonia established his residence at the mouth of the Duna, at Riga. In 1202 or 1204 Innocent III. recognized the Order of Brothers of the Sword (*Schwertbrüder*), the residence of its grandmaster being at Riga, and the order, spreading the Christian religion by sword and fire among the natives, carried on from that time a series of uninterrupted wars against the Russian republics and Lithuania, as well as a struggle against the influence of the archbishop of Riga, which last was supported by the importance acquired by Riga as a centre for trade, intermediate between the Hanseatic towns and those of Novgorod, Pskov, and Pologda. The first active interference of Lithuania in the affairs of Livonia dates from the times which immediately followed the great outbreak of peasants on Oel; Olgier devastated them all southern Livonia. The order happening to purchase the Danish part of Esthonia, in 1247, began to fight, fresh forces the war against the bishop of Riga, as well as against Lithuania, Poland, and the Russians. The wars against those powers were terminated respectively in 1435, 1466, and 1483. About the end of the 15th century the master of the order, Plettenberg, acquired a position of great importance, and in 1537 he was recognized as prince of the empire by Charles V. On the other hand, the authority of the bishops of Riga was soon completely

destroyed (1666). The war of the order with John IV. in 1560 led to a division of Livonia, its northern part, Dorpat included, being taken by Russia, and the southern part falling under the dominion of Poland. From that time Livonia formed a subject of dispute between Poland and Russia, the latter only formally abdicating its rights to the country in 1862. In 1621 it was the theatre of a war between Poland and Russia, and was conquered by the latter power, enjoying thus for twenty-five years a milder rule. In 1654, and again at the beginning of the 17th century, it became the theatre of war between Poland, Russia, and Sweden, and at last was finally conquered by Russia. The official concession was confirmed by the treaty of Nydztal in 1721, Russia guaranteeing the privileges of the nobility and citizens, and the freedom of the evangelical confession. (P. A. K.)

LIVY, the Roman historian, belonged by birth to those regions of northern Italy which had already given to Roman literature Catullus, Cornelius Nepos, and Virgil. He was born in 69 B.C., the year of Caesar's first consulship, and was thus eleven years younger than Virgil and six years younger than Horace. His native city Padua (Patavium) could challenge comparison, in the days of Augustus, even with such great centres of industry as Alexandria or Gades; and, while its active municipal life, and long traditions of hard won independence, may have quickened Livy's sympathies with republican freedom, its ancient connexion with Rome naturally helped to turn his attention to the study which became the work of his life. For Padua claimed, like Rome, a Trojan origin, and Livy is careful to place Antenor, the founder of Padua, side by side with Æneas. A more real bond of union was found in the dangers to which both had been exposed from the assaults of the Celts (Livy, x. 2), and Padua must have been drawn to Rome, as the conqueror of her hereditary foes, by much the same motives as those which led the Greeks in southern Italy to seek Roman aid against the Oscan invader. Moreover, at the time of Livy's birth, Padua had long been in possession of the full Roman franchise, and it is possible that the historian's family name had been taken by one of his ancestors out of compliment to the great Livian gens at Rome, whose connexion with Cisalpine Gaul is a well-established fact (Livy, xxvii. 35; Suet., *Tib.* 3), and by one of whom his family may have been enfranchised.

Livy's easy, independent life at Rome, and his aristocratic leanings in politics, have been taken as proof that he was the son of well-born and opulent parents, and it is certain that he was able to afford the luxury of a good education, for he was widely read in Greek literature, and a student both of rhetoric and philosophy. We have also evidence in his writings that he had prepared himself for his great work by researches into the history of his native town. His youth and early manhood, spent perhaps chiefly at Padua, were cast in stormy times, and the impression which they left upon his mind was ineffaceable. He was ten years old when Cæsar crossed the Rubicon and civil war began. In his fifteenth year came the murder of the great dictator, of whom he afterwards declared that he knew not "whether it were better for him to have been born or not," and one year later the murder of Cicero, to whose memory he paid an eloquent tribute. Of the part taken by Padua in the troubles which distracted the empire from 49 B.C. till the decisive victory at Actium we know nothing beyond the fact that in 43 B.C. it closed its gates against Antony, and was afterwards punished for doing so by Asinius Pollio. Livy's personal sympathies were with Pompey and the republican party (Tac., *Ann.*, iv. 34); but far more lasting in its effects was his experience of the licence, anarchy, and confusion of these dark days. The rule of Augustus he seems to have accepted as a necessity, but he cannot, like Horace and Virgil, welcome it as inaugurating a new and glorious era. While he endeavours to stifle his recollections of the horrors

he had witnessed, by fixing his whole mind on older and better times, he writes of the present with despondency as a degenerate and declining age; and, instead of triumphant prophecies of world-wide rule, such as we find in Horace, Livy contents himself with pointing out the dangers which already threatened Rome, and exhorting his contemporaries to learn, in good time, the lessons which the past history of the state had to teach.

It was probably about the time of the battle of Actium that Livy established himself in Rome, and there he seems chiefly to have resided until his retirement to Padua shortly before his death. We have no evidence that he travelled much, though he must have paid at least one visit to Campania (xxviii. 56), and he never, so far as we know, took any part in political life. Nor, though he enjoyed the personal friendship and patronage of Augustus (Tac., *Ann.*, iv. 34), and stimulated the historical zeal of the future emperor Claudius (Suet., *Claud.*, xli.), can we detect in him anything of the courtier. There is not in his history a trace of that rather gross adulation in which even Virgil does not disdain to indulge. His republican sympathies were freely expressed, and it should be added, as freely pardoned by Augustus. We must imagine him devoted to the great task which he had set himself to perform, with a mind, as he tells us himself in his preface, free from all disturbing cares, and in the enjoyment of all the facilities for study afforded by the Rome of Augustus, with its liberal encouragement of letters, its newly-founded libraries, and its brilliant literary circles. As his work went on, the fame which he had never coveted came to him in ample measure. He is said to have declared in one volume of his history that he had already won glory enough, and the younger Pliny (*Epist.*, ii. 3) relates that a Spaniard came all the way from Gades merely to see him, and, thus accomplished, at once returned home satisfied. The accession of Tiberius (14 A.D.) materially altered for the worse the prospects of literature in Rome, and Livy may have feared for himself the fate which afterwards befell Crenatius Cordus, who was tried before the senate, for having in his annals spoken of Brutus and Cassius as the last of the Romans (Tac., *Ann.*, iv. 34). However this may have been, Livy retired to Padua, and died there in the third year of the reign of Tiberius (17 A.D.), at the ripe age of seventy-six. When we have added that he had at least one son (Quintil., x. 1), who was possibly also an author (Pliny, *Nat. Hist.*, i. 5, 6), and a daughter married to a certain L. Magnus, a rhetorician of no great merit (Seneca, *Controu.*, x. 29, 2), we have reached the end of all that is known with certainty of Livy's personal history; and the apocryphal nature of the details which have been added by later admirers has been too often exposed to make it necessary to deal with them here.¹

But for us, as for Livy himself, the interest of his life centres in the work to which the greater part of it was devoted. For we must decline to believe with Niebuhr that his history was all written in his later years. On the contrary, various indications point to the period from 27 to 30 B.C., at that during which the first decade was written. In the first book (i. 19) the emperor is called Augustus, a title which he assumed early in 27 B.C., and in ix. 18 the omission of all reference to the restoration, in 20 B.C., of the standards taken at Carrus seems to justify the inference that the passage was written before that date. In the third decade, the allusion in xxviii. 12 to victories in Spain may, as Weissenborn thinks, refer to Agrippa's campaigns in 19 B.C., but the words "*ductus auspicioque Augusti Cæsarum*" point more naturally to those of Augustus

¹ For Livy's life see the introduction to Weissenborn's edition, Berlin, 1871, and the article in Smith's *Dictionary of Biography*.

himself, 37-35 B.C. In the epitome of book lix, there is a reference to a law of Augustus which was passed in 18 B.C. The books dealing with the civil wars must have been written during Augustus's lifetime, as they were read by him (*Tac. Ann.* iv. 34), while there is some evidence that the last part of the work, from book cxxi. onwards, was published after his death (14 A.D.).

Livy's history begins with the landing of Æneas in Italy, and closes with the death of Drusus, 9 A.D., though it is possible that he intended to continue it as far as the death of Augustus. The original title of the work is unknown, but of its general plan it is possible to speak with more certainty. The division into decades is certainly not due to the author himself, and is first heard of at the end of the 5th century; on the other hand, the division into "libri" or "volumina" seems to be original. It is referred to by Livy himself (x. 31, "per quantum jam volumen"; cxxi. 1, "multa volumina"), as well as by Pliny (*N. H.*, *pref.*) and by later writers. That the books were grouped and possibly published in sets is rendered probable both by the prefaces which introduce new divisions of the work (vi. 1, xxi. 1, xxxi. 1) and by the description in one MS of books cix.-cxvi. as "bellosum civilium libri octo." Such arrangement and publication in parts were moreover common with ancient authors, and in the case of a lengthy work almost a necessity.

Of the 142 "libri" composing the history, the first 15 carry us down to the eve of the great struggle with Carthage, a period, as Livy reckons it, of 488 years (xxi. 1); 16 more (xvi.-xxx) cover the 63 years of the two great Punic wars. With the close of book xlv we reach the conquest of Macedonia in 167 B.C. Book lvi. described the tribunate of Tiberius Gracchus, 133 B.C. In book lxxxix. we have the dictatorship of Sulla (81 B.C.), in ciii. Cæsar's first consulship (69 B.C.), in cix.-cxvi. the civil wars to the death of Cæsar (44 B.C.), in ccxv. the defeat of Brutus and Cassius at Philippi, in ccxxiii. and ccxxv. the battle of Actium and the accession of Augustus. The remaining eight books give the history of the first twenty years of Augustus's reign.

Such an outline was the vast work of which Martial (xiv. 190) complains that his whole library could not contain it. But a small portion of it, however, has come down to modern times, only thirty-five books are now extant (i.-x., xx.-xlv.), and of these xli. and xlii. are incomplete. The lost books seem to have disappeared between the 7th century and the revival of letters in the 15th,—a fact sufficiently accounted for by the difficulty of transmitting so voluminous a work in times when printing was unknown, for the story that Pope Gregory I. burnt all the copies of Livy he could lay his hands on rests on no good evidence. Only one important fragment has since been recovered,—the portion of book xx. discovered in the Vatican in 1773, and edited by Niebuhr in 1820. Very much no doubt of the substance of the lost books has been preserved both by such writers as Plutarch and Dion Cassius, and by epitomizers like Florus and Eutropius. But our knowledge of their contents is chiefly derived from the so-called "periœchæ" or epitomes, of which we have fortunately a nearly complete series, the epitomes of books cxxvii. and cxxviii. being the only ones missing. These epitomes have been ascribed without sufficient reason to Florus (2d century); but, though they are probably of even later date, and are disappointingly meagre, they may be taken as giving, so far as they go, a fairly authentic description of the original. They have been expanded with great ingenuity and learning by Freinsheim in Drakenborch's edition of Livy.¹

The reserved text of the extant thirty-five books of Livy is taken from different sources, and no one of our MSS contains them all. The MSS of the first decade, some thirty in number, are with one exception derived, more or less directly, from a single archetype, viz. the recension made in the 4th century by the two Nicomachi, Flavianus and Dexter (not by one only, as Niebuhr thought), and by Victorinus. This is proved in the case of the older MSS by written subscriptions to that effect, and in the case of the rest by internal evidence. Of all these descendants of the Nicomachean recension, the oldest is the Codex Parisinus of the 10th century, and the best the Codex Mediceus or Florentinus of the 11th. An independent value attaches to the ancient palimpsest of Verona, of which the first complete account was given by Aicimicus as recently as 1858 (*Biblioth. Mondadori*, January). It contains the third, fourth, fifth, and fragments of the sixth book, and, according to Mommsen, whose conclusions are accepted by Madvig (*Ætius Læmæus*, 2d ed. 1877, p. 37), it is derived, not from the Nicomachean recension, but from an older archetype common to both.

For the third decade our chief authority is the Codex Puteanus, an uncial MS of the 8th century, now at Paris. For the fourth we have two leading MSS,—Codex Bambergenus, 11th century, and the slightly older Codex Moguntinus, which is only known through the Mainz edition of 1618-19. What remains of the fifth decade depends on the Lausannensis or Vindobonensis from the monastery of Lorsch, dated at Basel in 1581. It belongs to the 6th century.

If we are to form a correct judgment on the merits of Livy's history, we must, above all things, bear in mind what his aim was in writing it, and this he has told us himself in the celebrated preface which Niebuhr rather unaccountably denounces as "the worst part of his work" (*Introd. Lect.*, p. 60). He set himself the task of recording the history of the Roman people, "the first in the world," from the beginning. The task was a great one, and the fame to be won by it uncertain, yet it would be something to have made the attempt, and the labour itself would bring a welcome relief from the contemplation of present evils; for his readers too this record will, he says, be full of instruction: they are invited to note especially the moral lessons taught by the story of Rome, to observe how Rome rose to greatness by the simple virtues and unselfish devotion of her citizens, and how on the decay of these qualities followed degeneracy and decline.

He does not therefore write, as Polybius wrote, for students of history. With Polybius the greatness of Rome is a phenomenon to be critically studied and scientifically explained; the rise of Rome forms an important chapter in universal history, and must be dealt with, not as an isolated fact, but in connexion with the general march of events in the civilized world. Still less has Livy anything in common with the naive anxiety of Dionysius to make it clear to his fellow Greeks that the irresistible people who had mastered them was in origin, in race, and in language Hellenic like themselves.

Livy writes as a Roman, to raise a monument worthy of the greatness of Rome, and to keep alive, for the guidance and the warning of Romans, the recollection alike of the virtues which had made Rome great and of the vices which had threatened her with destruction. In so writing he was in close agreement with the traditions of Roman literature, as well as with the conception of the nature and objects of history current in his time. To a large extent Roman literature grew out of pride in Rome, for, though her earliest authors took the form and often the language of their writings from Greece, it was the greatness of Rome that inspired the best of them, and it was from the annals of Rome that their themes were taken. And this is naturally true in an especial sense of the Roman historians, the long list of annalists begins at the moment when the great struggle with Carthage had for the first time brought Rome into direct connexion with the historic peoples of the ancient world, and when Romans themselves awoke to the importance of the part reserved for Rome to play in universal history. To write the annals of Rome became at once a task worthy of the best of her citizens. Though

¹ The various recensions since current of complete copies of Livy in Constantinople, China, and elsewhere are noticed by Niebuhr, *Introd. Lect.*, p. 87, Eng. transl. See also Pauly, *Real-Encyclopædie*, s. v.

other forms of literature might be thought unbecoming to the dignity of a free-born citizen, this was never so with history. On the contrary, men of high rank and tried statesmanship were on that very account thought all the fitter to write the chronicles of the state they had served. And history in Rome never lost either its social prestige or its intimate and exclusive connexion with the fortunes of the Roman people. It was well enough for Greeks to busy themselves with the manners, institutions, and deeds of the "peoples outside." The Roman historians, from Fabius Pictor to Tacitus, cared for none of these things. This exclusive interest in Rome was doubtless encouraged by the peculiar characteristics of the history of the state. The Roman annalist had not, like the Greek, to deal with the varying fortunes and separate doings of a number of petty communities, but with the continuous life of a single city. Nor was his attention drawn from the main lines of political history by the claims of art, literature, and philosophy, for just as the law which bound Romans together was that of citizenship, not of race or culture, so the history of Rome is that of the state, of its political constitution, its wars and conquests, its military and administrative system.

Livy's own circumstances were all such as to render these views natural to him. He began to write at a time when, after a century of disturbance, the mass of men had been contented to purchase peace at the price of liberty. The present was at least inglorious, the future doubtful, and many turned gladly to the past for consolation. This retrospective tendency was favourably regarded by the Government. It was the policy of Augustus to obliterate all traces of recent revolution, and to connect the new imperial regime as closely as possible with the ancient traditions and institutions of Rome and Italy. The *Æneid* of Virgil, the *Fasts* of Ovid, suited well with his own restoration of the ancient temples, his revival of such ancient ceremonies as the *Ludi Sæculares*, his efforts to check the un-Roman luxury of the day, and his jealous regard for the purity of the Roman stock. And, though we are nowhere told that Livy undertook his history at the emperor's suggestion, it is certain that Augustus read parts of it with pleasure, and even honoured the writer with his assistance and friendship.

Livy was deeply penetrated with a sense of the greatness of Rome. From first to last its majesty and high destiny are present to his mind. Æneas is led to Italy by the fates that he may be the founder of Rome (l. i; comp. i. 4, "debeatur fati tante origo urbis"). Romulus after his ascension declares it to be the will of heaven that Rome should be mistress of the world; and Hannibal marches into Italy, that he may "set free the world" from Roman rule. But, if this ever-present consciousness often gives dignity and elevation to his narrative, it is also responsible for some of its defects. It leads him occasionally into exaggerated language (e.g., xiii. 33, "nullus unquam terrarum rei cum Romanos effugiebat"), or into such misstatements as that in xxi. 99, where he explains the course taken by the Romans in renewing war with Carthage by saying that "it seemed more suitable to the dignity of the Roman people." Often his jealousy for the honour of Rome makes him unfair and one-sided. In all her wars not only success but justice is with Rome (e.g., the war with Persius of Macedonia; see Cobet in *Mnemosyne* for 1881). When Hieronymus of Syracuse deserts Rome for Hannibal, Livy says nothing of the complaints against Rome, by which, according to Polybius, he justified his change of policy. To the same general attitude is also due the omission by Livy of all that has no direct bearing on the fortunes of the Roman people. "I have resolved," he says (xxix. 48), "only to touch on foreign affairs so far as they are bound up with those of Rome." The operations of the Rhodians in Asia Minor (197 B.C., xxxiii. 20)

he curtly dismisses in a sentence, that he may pass "ad æque propria Romani belli sunt," and so again (xli. 25) "it is not worth my while to recount in detail the wars of foreigners with each other; it is as much and more than I can do to record the doings of the Roman people." As the result, we get from Livy very defective accounts even of the Italic peoples most closely connected with Rome. Of the past history and the internal condition of the more distant nations he encountered he tells us little or nothing, even when he found such details carefully given by Polybius.

Scarcely less strong than his interest in Rome is his interest in the moral lessons which his history seemed to him so well qualified to teach. This didactic view of history was a prevalent one in antiquity, and it was confirmed no doubt by those rhetorical studies which in Rome as in Greece formed the chief part of education, and which taught men to look on history as little more than a storehouse of illustrations and themes for declamation. But it suited also the practical bent of the Roman mind, with its comparative indifference to abstract speculation or purely scientific research. It is in the highest degree natural that Livy should have sought for the secret of the rise of Rome, not in any large historical causes, but in the moral qualities of the people themselves, and that he should have looked upon the contemplation of these as the best remedy for the vices of his own degenerate days. It is possible too that the simplicity and even austerity of manners for which Padua was afterwards celebrated may have characterized its citizens in Livy's time, and that he was thus especially fitted to appreciate the purity, reverence, and loyalty of early Rome. But, whatever the cause, there is no doubt of the fact. He is never tired of insisting on the virtues of past days, or of contrasting them with the vices of the present. He dwells with delight on the unselfish patriotism of the old heroes of the republic. In those times children obeyed their parents, the gods were still sincerely worshipped, poverty was no disgrace, sceptical philosophies and foreign fashions in religion and in daily life were unknown. But this ethical interest is closely bound up with his Roman sympathies. His moral ideal is no abstract one, and the virtues he prizes are those which in his view made up the truly Roman type of character. "Munus Romani ingenii homo" is the sentence of condemnation he passes (xxii. 58) on a Roman soldier who broke faith with Hannibal. Camillus is praised as "vir ac vere Romanus" (xxii. 14); "to do and to suffer bravely" is Roman (li. 12). The prominence thus given to the moral aspects of the history tends to obscure in some degree the true relations and real importance of the events narrated, but it does so in Livy to a far less extent than in some other writers. He is much too skilful an artist either to resolve his history into a mere bundle of examples, or to overload it, as Tacitus is sometimes inclined to do, with reflexions and axioms. The moral he wishes to enforce is usually either conveyed by the story itself, with the aid perhaps of a single sentence of comment, or put as a speech into the mouth of one of his characters (e.g., xxiii. 49; the devotion of Decius, viii. 10, comp. vii. 40; and the speech of Camillus, v. 54); and what little his narrative thus loses in accuracy it gains in dignity and warmth of feeling. In his portraits of the typical Romans of the old style, such as Q. Fabius Maximus, in his descriptions of the unshaken firmness and calm courage shown by the fathers of the state in the hour of trial, Livy is at his best; and he is so largely in virtue of his genuine appreciation of character as a powerful force in the affairs of men.

This enthusiasm for Rome and for Roman virtues is, moreover, saved from degenerating into gross partiality by the genuine candour of Livy's mind and by his wide sympathies with every thing great and good. Seneca has

described him as "candidissimus omnium magnorum ingenium aestimator" (*Suetonius*, vi. 21). Quintilian (x. 1, 101) places him on a level with Herodotus as a writer "clarissimi candoris," and this candid admiration is not reserved exclusively for Romans. *Hasdrubal's* devotion and valour at the battle on the Metaurus are described in terms of eloquent praise (xxvii. 49, "there, as became the son of Hamilcar and the brother of Hannibal, he fell fighting"); and even in Hannibal, the lifelong enemy of Rome, he frankly recognizes the great qualities that balanced his faults. Nor though his sympathies are unmistakably with the aristocratic party, does he scruple to censure the pride, cruelty, and selfishness which too often marked their conduct (ii. 54; the speech of *Cenuleus*, iv. 3; of *Sextus* and *Licinus*, vi. 36), and, though he feels acutely that the times are out of joint, and has apparently little hope of the future, he still believes in justice and goodness. He is often righteously indignant, but never satirical, and such a pessimism as that of *Tacitus* and *Juvenal* is wholly foreign to his nature.

Though he studied and even wrote on philosophy (*Seneca*, *Epist.* 100), *Livy* is by no means a philosophic historian. We learn indeed from incidental notices that he inclined to Stoicism and disliked the Epicurean system. With the scepticism that despised the gods (x. 40) and denied that they meddled with the affairs of men (xlii. 13) he has no sympathy. The immortal gods are everywhere the same (xlii. 3); they govern the world (xxvii. 46) and reveal the future to men by signs and wonders (xlii. 13), but only a debased superstition will look for their hand in every petty incident (xxvii. 23, "minimis etiam rebus prava religio inserit deos"), or abandon itself to an indiscriminate belief in the portents and miracles in which popular credulity delights (xxviii. 11, xxi. 63, "multa ex hieme prodigia . . . aut quod evenire solat, motis semel in religionem animis, multa nunciata et temere credita"). The ancient state religion of Rome, with its temples, priests, and auguries, he not only reverences as an integral part of the Roman constitution, with a sympathy which grows as he studies it (xlii. 13, "et mihi vetustas res scribenda, nescio quo pacto antiquus sit animus"), but, like *Varro*, and in true Stoic fashion, he regards it as a valuable instrument of government (i. 19, 21), indispensable in a well-ordered community. As distinctly Stoical is the doctrine of a fate to which even the gods must yield (ix. 4), which disposes the plans of men (i. 42) and blinds their minds (v. 37), yet leaves their will free (xxxvii. 46).

But we find no trace in *Livy* of any systematic application of philosophy to the facts of history. He is as innocent of the leading ideas which shaped the work of *Polybius* as he is of the cheap theorizing which worries us in the pages of *Dionysius*. The events are graphically, if not always accurately, described; but of the larger causes at work in producing them, of their subtle action and reaction upon each other, and of the general conditions amid which the history worked itself out, he takes no thought at all. Nor has *Livy* much acquaintance with either the theory or the practice of politics. He exhibits, it is true, political sympathies and antipathies. He is on the whole for the nobles and against the commons; and, though the unfavourable colours in which he paints the leaders of the latter are possibly reflected from the authorities he followed, it is evident that he despised and disliked the multitude (xxiv. 35, "aut servit humiliter aut superbe dominatur"). Of monarchy he speaks with a genuine Roman hatred, and we know that in the last days of the republic his sympathies were wholly with those who strove in vain to save it. He betrays too an insight into the evils which were destined finally to undermine the imposing fabric of Roman empire. The

decline of the free population, the spread of slavery (vi. 12, vii. 25), the universal craving for wealth (iii. 26), the employment of foreign mercenaries (xxv. 33), the corruption of Roman race and Roman manners by mixture with aliens (xxxix. 3), are all noted in tones of solemn warning. But his retired life had given him no wide experience of men and things. It is not surprising, therefore, to find that he fails altogether to present a clear and coherent picture of the history and working of the Roman constitution, or that his handling of intricate questions of policy is weak and inadequate.

If from the general aim and spirit of *Livy's* history we pass to consider his method of workmanship, we are struck at once by the very different measure of success attained by him in the two great departments of an historian's labour. He is a consummate artist, but an unskilled and often careless investigator and critic. The materials which lay ready to his hand may be roughly classed under two heads:—(1) the original evidence of monuments, inscriptions, &c., (2) the written tradition as found in the works of previous authors. It is on the second of these two kinds of evidence that *Livy* almost exclusively relies. Yet that even for the very early times a certain amount of original evidence still existed is proved by the use which was made of it by *Dionysius*, who mentions at least three important inscriptions, two dating from the regal period and one from the first years of the republic (iv. 26, iv. 68, x. 32). We know from *Livy* himself that the breastplate dedicated by *Cossus* (428 a.d.) was to be seen in his own day in the temple of *Jupiter Feretrius*, nor is there any reason to suppose that the "libri lintei," quoted by *Licinius Macer*, were not extant when *Livy* wrote. For more recent times the materials were plentiful, and a rich field of research lay open to the student in the long series of laws, decrees of the senate, and official registers, reaching back, as it probably did, at least to the commencement of the 3d century a.d. Nevertheless it seems certain that *Livy* never realized the duty of consulting these relics of the past, even in order to verify the statements of his authorities. Many of them he never mentions; the others (*e.g.*, the libri lintei) he evidently describes at second hand. Antiquarian studies were popular in his day, but the instances are very few in which he has turned their results to account. There is no sign that he had ever read *Varro*; and he never alludes to *Verrius Flaccus*. The haziness and inaccuracy of his topography make it clear that he did not attempt to familiarize himself with the actual scenes of events even that took place in Italy. Not only does he confuse *Thermopylae*, the capital of *Attolia*, with *Thermopylae* (xxxiii. 35), but his accounts of the Roman campaigns against *Volsci*, *Aequi*, and *Sammites* swarm with confusions and difficulties; nor are even his descriptions of *Hannibal's* movements free from an occasional vagueness which betrays the absence of an exact knowledge of localities.

The consequence of this indifference to original research and patient verification might have been less serious had the written tradition on which *Livy* preferred to rely been more trustworthy. But neither the materials out of which it was composed, nor the manner in which it had been put together, were such as to make it a safe guide. It was indeed represented by a long line of respectable names. The majority of the Roman annalists were men of high birth and education, with a long experience of affairs, and their defects did not arise from seclusion of life or ignorance of letters. It is rather in the conditions under which they wrote and in the rules and traditions of their craft that the causes of their shortcomings must be sought.

It was not until the 6th century from the foundation of the city that historical writing began in Rome. The father of Roman history, *Q. Fabius Pictor*, a patrician and a senator, can scarcely have published his annals before the close of the Second Punic War, but these annals covered the whole period from the arrival of *Evander* in Italy down at least to the battle by *Lake Trasimene* (217 a.d.). Out of what materials, then, did he put together his account of

the earlier history? Recent criticism has succeeded in answering this question with some degree of certainty. A careful examination of the fragments of Fabius (see H. Peter, *Historicum Romanorum Reliquiae*, Leipzig, 1870, and Nitzsch, *Röm. Annalistik*, Berlin, 1878) reveals in the first place a marked difference between the hasty period, and that which followed the establishment of the republic. The history of the former stretches back into the regions of pure mythology. It is little more than a collection of fables told with scarcely any attempt at criticism, and with no more regard to chronological sequence than was necessary to make the tale run smoothly or to fill up such gaps as that between the flight of Aeneas from Troy and the supposed year of the foundation of Rome. But from its very commencement the history of the republic was a different aspect. The mass of floating tradition, which had come down from early days, with its tales of border raids and forays, of valiant chiefs, and deeds of patriotism, is now rudely fitted into a framework of a wholly different kind. This framework consists of slight notices of important events, wars, prodigies, consecration of temples, &c., all recorded with extreme brevity, precisely dated, and couched in a somewhat archaic style. They were taken probably from one or more of the stetes regentes, such as the annals of the pontiffs, or those kept by the aediles in the temple of Ceres. These have official outline of the past history of his city was by Fabius filled in from the rich store of tradition that lay ready to his hand. The manner and spirit in which he effected this combination were no doubt wholly marvellous. Usually he seems to have transferred both annalistic notices and popular traditions to his pages much in the shape in which he found them. But he unquestionably gave undue prominence to the tales of the prowess and glory of the Fabii, and probably also allowed his own strong antioptic sympathies to colour his version of the early political controversies. These faults of partiality were, according to Polybius, a conspicuous blot in Fabius's account of his own times, which was, we are told, full and in the main accurate, and, like the earlier portions, consisted of official annalistic notices, supplemented, however, not from tradition, but from his own experience and from contemporary sources. But even here Polybius charges him with favouring Rome at the expense of Carthage, and with the undue exaltation of the great head of his house, Q. Fabius Cunctator.

Nevertheless the comparative fidelity with which Fabius seems to have reproduced his materials might have made his annals the starting point of a critical history. But unfortunately intelligent criticism was exactly what they never received. It is true that in some respects a decided advance upon Fabius was made by subsequent annalists. M. Porcius Cato (234-183 b.c.) widened the scope of Roman history to include that of the chief Italian cities, and made the first serious attempt to settle the chronology. In his history of the Punic was Caelius Antipater (c. 180 b.c.) added fresh material, drawn probably from the works of the Sicilian Greek Silenus, while Licinius Macer (70 b.c.) distinguished himself by the use he made of the most "litterate books." No doubt, too, the later annalists, at any rate from Caelius Antipater onwards, improved upon Fabius in treatment and style. But in more essential points we can discern no progress. One annalist after another quietly adopted the established tradition, as it had been left by his predecessors, without any serious alterations of its main outline. Of independent research and critical analysis we find no trace, and the general agreement upon main facts is to be attributed simply to the regularity with which each writer copied the one before him. But, had the later annalists contented themselves with merely reproducing the earlier ones, we should at least have had the old traditions before us in a simple and tolerably genuine form. As it was, while they slavishly cling to its substance, they succeeded as a rule in destroying all traces of its original form and colouring. L. Calpurnius Piso, tribune in 149 b.c. and consul in 138 b.c., prided himself on reducing the old legends to the level of common sense, and importing into them the valuable moral lessons for his own generation. By Caelius Antipater the methods of rhetoric were first applied to history, a disastrous precedent enough. His inserted speeches, enlivened his pages with chance tales, and aimed, as Cicero tells us, at not merely making his tale more attractive, but to instruct his readers. His successors carried still further the practice of dressing up the rather bald chronicles of earlier writers with all the ornaments of rhetoric. The old traditions were altered, almost beyond the possibility of recognition, by exaggerations, interpolations, and additions. Fresh incidents were introduced, new motives suggested, and speeches composed in order to infuse the required life and freshness into these dry bones of history. At the same time the political bias of the writers, and the political ideas of their day were allowed, in some cases perhaps half unconsciously, to affect their representations of past events. Annals of the Gracchi age imported into the story of patriotism and pietism the elements of the economic controversies of their own day, and painted the first tribunes in the colours of the two Gracchi or of Saturninus. In the next generation they dexterously forced the venerable records of the early republic to pronounce in favour of the ascendancy of the

senate, as established by Sulla. To political bias was added family pride, for the gratification of which the archives of the great houses, the funeral pyres, or the imagination of the writer himself supplied an ample store of doubtful material. Pedigrees were invented, imaginary consuls and fictitious triumphs inserted, and family traditions and family honours were formally incorporated with the history of the state.

Things were not much better even where the annalists were dealing with recent or contemporary events. Here indeed their materials were naturally fuller and more trustworthy, and less room was left for fanciful decoration and capricious alteration of the facts. But their methods are in the main unchanged. Yet they found written they copied, the gaps they supplied, where personal experience failed, by imagination. No better proof of this can be given than a comparison of the annalist's version of history with that of Polybius. In the fourth and fifth decades of Livy the two appear side by side, and the contrast between them is striking. Polybius, for instance, gives the number of the army at Cynoscephalae as 8000, the annalists raise it as high as 40,000 (Liv. xxiii. 10). In another case (xxiii. 6) Valerius Antias, the chief of sinners in this respect, inserts a decisive Roman victory over the Macedonians, in which 12,000 of the latter were slain and 100 taken prisoners, an achievement recorded by no other authority. In some parts of those two decades, however, Livy gives us only the annalist's story. Of the campaigns in Cisalpine Gaul, Liguria, and Spain, as described by him on their authority, Nissen will remark (*Gr. und Röm. Gesch.* 94), "One would think that the Gauls, Ligurians, and Spaniards were there for the sole purpose of being slaughtered in thousands by the Romans. Year after year they rise in revolt against Rome, lose some 40,000 men in the struggle, and finally submit, only to begin the same game afresh the next year."

Such was the written tradition on which Livy mainly relied. We have next to examine the manner in which he used it, and here we are met at the outset by the difficulty of determining with exactness what authorities he is following at any one time, for of the importance of full and accurate references to the sources of the chapters together he gives us no clue at all. More often still he contents himself with such vague phrases as "they say," "the story goes," "some think," or speaks in general terms of "ancient writers" or "my authorities." Even where he mentions a writer by name, it is frequently clear that the name is merely a name, the whose lead he is following at the moment, but that he is not actually as differing from Livy's guide for the time being on some point of detail (compare the references to Piso in the first decade, l. 55, n. 52, &c.). It is very rarely that Livy explicitly tells us whom he selects as his source (e.g. Fabius, xx. 7; Polybius, xxiii. 10). By a careful analysis, however, of those portions of his work which admit of a comparison with the text of his acknowledged authorities (e.g. fourth and fifth decades, see Nissen, *Untersuchungen*, Berlin, 1858), and elsewhere by comparing his version with the known fragments of the various annalists, and with what we are told of their style and method of treatment, we are able to form a general idea of his plan of procedure. As to the first decade, it is generally agreed that in the first and second books at any rate he follows much older and simpler writers as Fabius Pictor and Calpurnius Piso (the only one whom he there refers to by name), to whom, so far as the first book is concerned, Niebuhr (*Introd. Lect.* p. 23) would add the poet Ennius. With the close of the second book or the opening of the third we come upon the first traces of the use of later authors. Valerius Antias is first quoted in ii. 6, and many of his landmarks are visible here and there throughout the rest of the decade (viii. 38, ix. 27, x. 8-6). In the fourth book the principal authority is apparently Licinius Macer, and for the period following the sack of Rome by the Gauls Q. Claudius Quadrigarius, whose annals began at this point in the first century. We have besides a single instance of the use of the quarian Censorius, and two (iv. 28, x. 9) of Q. Julius Tubero, one of the last in the list of annalists. Passing to the third decade, we find ourselves at once confronted by a question which has been long and fully discussed—the relation between Livy and Polybius. Did Livy use Polybius at all, and, if so, to what extent? (See for details Haller, *Gründriss zur Vorlesung üb. d. Röm. Literaturgeschichte*, p. 195.)

It is conceded on all hands that Livy in this decade makes considerable use of other authorities than Polybius (e.g. Fabius, xxiii. 1; Caelius Antipater, xxiii. 38, 46, 47, xxiii. 41, &c.), but he only once mentions Polybius (xxv. 45, "Polybius huiusmodi sperandus auctor"), and that, if he used him, he did so to a much less extent than in the fourth and fifth decades, and in a very different manner. It is also agreed that we can detect in Livy's account of the Hannibalic war two distinct documents, derived originally, the one from a Roman, the other from a non-Roman source. But from these generally accepted premises two opposite conclusions have been drawn. On the one hand, it is maintained (e.g., by Leachmann, Q. Peter, H. Peter, *Hist. Rom. Reliq.*) that those parts of Livy's narrative which point to a non-Roman authority (e.g. Hannibal's

movements (prior to his invasion of Italy) are taken by Livy directly from Polybius, with occasional reference of course to other writers, and with the omission (as in the later decades) of all matters uninteresting to Livy or his Roman readers, and the addition of rhetorical touches and occasional comments. It is urged that Livy, who in the fourth and fifth decades shows himself so sensible of the great merits of Polybius, is not likely to have ignored him in the third, and that his more limited use of him in the latter case is fully accounted for by the closer connexion of the history with Rome and Roman affairs, and the comparative excellence of the available Roman authorities, and, lastly, that the points of agreement with Polybius, not only in matter but in expression, can only be explained on the theory that Livy is directly following the great Greek historian. On the other hand, it is maintained (especially by Schweigler, Nitzsch, and K. Bötcher) that the extent and nature of Livy's agreement with Polybius in this part of his work point rather to the use by both of a common original authority. It is argued that Livy's mode of using his authorities is tolerably uniform, and that his mode of using Polybius in particular is known with certainty from the later decades. Consequently the theory that he used Polybius in the third decade requires us to assume that in this one instance he departed widely, and without sufficient reason, from his usual course of procedure. Moreover, in the passages where the agreement with Polybius is most apparent, there are so many discrepancies and divergences in detail, and so many unaccountable omissions and additions, as to render it inconceivable that he had the text of Polybius before him. But all these are made intelligible if we suppose Livy to have been here following directly or indirectly the same original sources that were used by Polybius. The earliest of these original sources was probably Silenus, with whom may possibly be placed, for books xxi, xxii, Fabius Pictor. The latter Livy certainly used directly for some parts of the decade. The former he almost certainly knew only at second hand, the intermediaries almost certainly being Calpurnius Antipater. This writer, who confined himself to a history of the Second Punic War, in seven books, is expressly referred to by Livy eleven times in the third decade; and in other passages where his name is not mentioned Livy can be shown to have followed him. Livy, x. 48, 50, 51; xxv. 9. In the latter books of the decade his chief authority is possibly Valerius Antias.

In the fourth and fifth decades the question of Livy's authorities presents no great difficulties, and the conclusions arrived at by Nissen in his masterly *Historia des Quellen der Abfassung des Livy'schen Geschichtswerkes* have been almost generally accepted. These may be shortly stated as follows. In the portions of the history which deal with Greece and the East, Livy follows Polybius, and these portions are easily distinguishable from the rest by their superior clearness, accuracy, and fulness. On the other hand, for the history of Italy and western Europe, Livy falls back on Roman annalists, especially, it seems, on Claudius Quadrigarius and Valerius Antias,—a most unfortunate choice,—and from them too he takes the annalistic mould into which his matter is cast.

Livy's general method of using these authorities was certainly not such as would be deemed satisfactory in a modern historian. He is indeed free from the grosser faults of deliberate injustice and falsification, and he resists that temptation to invent to which "the minds of authors are only too much inclined" (xxii. 7). Nor is he unconscious of the necessity for some kind of criticism. He distinguishes between rumour and the precise statements of recognised authorities (cf. xvi. 46, v. 21, vi. 8). The latter he reproduces in the main faithfully, but with a certain exercise of discretion. Where they disagreed, he calls attention to the fact, occasionally pronouncing in favour of one version rather than another (ii. 41, xxi. 48), though he sometimes decides groundlessly, or attempting to reconcile and explain discrepancies (vi. 13, 38). Where he detects or suspects the insertion of fabulous matter he has no scruple in saying so (e.g., i. 7, v. 21, "insertum hinc loco fabula"). Gross exaggerations, such as those in which Valerius Antias indulged, he roundly denounces (xxvii. 38, "exaggeratio numero non alius intemperanter?"), and with equal plainness of speech he condemns the family vanity which had so conspicuously corrupted and distorted the truth. "I suppose," he says (viii. 40), "that the record and memorial of these matters hath been depraved and corrupted by these funeral orations of praeses. . . . while every house and family dwelteth in Italy, and such like records, I mean neither to aver nor disprove" (xxvii. 37), and of the whole history he pronounces to the seek of Rome by the Gauls (390 s.c.) he writes that it was obscure "both in regard of exceeding antiquity, and also for that in those days there were very few writings and monuments, the only faithful safeguard and true remembrance of deeds past, and besides, whatsoever was registered in the commentaries of the

praetors and in other public or private records, the same for the most part, when the city was burned, perished withal." Further than this, however, Livy's criticism does not go. Where his written authorities are not palpably inconsistent with each other or with probability he accepts and transcribes their record without any second inquiry, nor does he ever attempt to get behind this record in order to discover the original evidence on which it rested. His acceptance in any particular case of the version given by an annalist by no means implies that he has by careful inquiry satisfied himself of its truth. At the most it only implies a comparison with other reasons, equally second-hand, but either less generally accepted or less in harmony with his own views of the situation; and in many cases the reasons he gives for his preference of one account over another are amply unscientific (e.g., xxvi. 49, "media similitudo visit"). Livy's history, then, rests on no foundation of original research or even of careful verification. It is a compilation, and even as such it leaves much to be desired. For we cannot credit Livy with having made such a preliminary survey of his authorities as would enable him to determine their relations to each other, and fuse their various narratives into a consistent whole. It is clear, on the contrary, that his endeavours in this direction were of a comparatively small one, that of these he selected one, and transcribed him with the necessary embellishments and other slight modifications until impelled by various reasons to drop him. He then, without warning, takes up another, whom he follows in the same way. The result is a curious mosaic, in which pieces of all colours and states of preservation are put together, and in which even the great artistic skill displayed throughout fails to conceal the lack of internal unity. Thus many of Livy's inconsistencies are due to his having placed together two versions, each of which gave a differently coloured account of the same event. Mommsen has clearly shown that this is what has happened in his relation of the legal proceedings against the elder Africanus in book xxviii. (*Röm. Forschungen*, i.), and in the story of the first secession, as he tells it, the older version which represented it as due to political and the later which explained it by economical grievances are found side by side. Similarly a change from one authority to another leads him not infrequently to copy from the one a statement inconsistent with those he took from the former, to forget what he has previously said, or to treat as known a fact which has not been mentioned before (cf. i. 1, xxiv. 6, and *Wissenstein's Introduction*, p. 57). In other cases where the same event has been placed by different annalists at different years, or where the versions of it varied, it is evident from Livy's treatment. Thus the four campaigns against the Volsci (ii. 17-20) as, as Schweigler (*R. G.*, i. 13) rightly says, simply variations of one single expedition. Other instances of such "doublets" are the two single combats described in xxiii. 46 and xxv. 18, and the two battles of Cannae in Spain (xxvii. 10 and 11). It is hardly possible to doubt too much of the chronological confusion above alluded to. Livy is due to the fact that he follows now one now another authority, heedless of their differences on this head. Thus he vacillates between the Catonian and Varroian reckoning of the years of the city, and between the chronologies of Polybius and the Roman annalists.

To these defects in his method must be added the fact that he does not always succeed even in accurately reproducing the authority he is for the time following. In the case of Polybius, for instance, he allows himself great freedom in omitting what strikes him as irrelevant, or tedious, or unnecessary to his Roman readers, a process in which much valuable matter disappears. In other cases his desire to give a vividness and point to what he doubtless considered the matter held and dry style of Polybius leads him into abridgements and inaccuracies. Thus by the treaty with Antiochus (188 s.c.) it was provided that the Greek communities of Asia Minor "shall settle their mutual differences" (xxvii. 37), and so forth. Livy correctly transcribes Polybius, but he adds with a rhetorical flourish, "or, if both parties prefer it, by war" (xxvii. 38). Elsewhere his blunders are apparently due to haste, ignorance, or sheer carelessness, thus, for instance, when Polybius speaks of the Etolians as settling at their capital Thermopylae, Livy (xxvii. 38) not only substitutes Thessaly, but gratuitously informs his readers that here the Pylians assembled were held Thians partly to carelessness, partly to misanthropia; he makes and unmakes (xxv. 6 s.c.) of Polybius's account of the battle of Gynocephalia, while in xxviii. 7 he mistakes *epopeis* ("silestis") for *epopae* ("dooms"), and makes nonsense of the passage accordingly. Finally, Livy cannot be altogether acquitted on the charge of having here and there modified Polybius in the interests of Rome, as when he gives an air of magnanimous moderation to the spoliation of Ambracia (189 s.c.), by adding, after describing the carrying away of all statues, houses, and pictures, "nulla preterea factum violantura" (xxviii. 9, comp. xlii. 19; and *Nissen's History*, i. 31).

Serious as these defects in Livy's method appear if viewed in the light of modern criticism, it is probable that they were easily pardoned, if indeed they were ever

discovered, by his contemporaries. For it was on the artistic rather than on the critical side of history that stress was almost universally laid in antiquity, and the thing that above all others was expected from the historian was not so much a scientific investigation and accurate exposition of the truth, as its skilful presentation in such a form as would charm and interest the reader. In this sense Cicero, *De Legg.* i, 2, speaks of history as an "opus oratorum," and Quintilian, x, 1, as "a prose poem" (*carmen solum*); and so we find that in the judgment of ancient critics it is by their artistic merits that historians stand or fall. Tried by this standard, Livy deservedly won and held a place in the very first rank. Asinius Pollio entered at his Patavinity, and the emperor Caligula denounced him as verbose, but with these exceptions the opinion of antiquity was unanimous in pronouncing him a consummate literary workman. The classical purity of his style, the eloquence of his speeches, the skill with which he depicted the play of emotion, and his masterly portraiture of great men, are all in turn warmly commended, and in our own day we question if any ancient historian is either more readable or more widely read. It is true that for us his artistic treatment of history is not without its drawbacks. The more trained historical sense of modern times is continually shocked by the obvious untruth of his colouring, especially in the earlier parts of his history, by the palpable unreality of many of the speeches, and by the narrative with which he omits everything, however important, which he thinks will weary his readers. But in spite of all this we are forced to acknowledge that, as a master of what we may perhaps call "narrative history," he has no superior in antiquity, for, inferior as he is to Thucydides, to Polybius, and even to Tacitus in philosophic power and breadth of view, he is at least their equal in the skill with which he tells his story. He is indeed the prince of chroniclers, and in this respect not unworthy to be classed even with Herodotus (*Quint.* x, 1). Nor is anything more remarkable than the way in which Livy's fine taste and sense of proportion, his true poetic feeling and genuine enthusiasm, saved him from the besetting faults of the mode of treatment which he adopted. The most superficial comparison of his account of the earliest days of Rome with that given by Dionysius shows from what depth of tediousness he was preserved by these qualities. Instead of the wearisome prolixity and the misplaced pedantry which make the latter almost unreadable, we find the old tales briefly and simply told. Their primitive beauty is not marred by any attempt to force them into an historical mould, or disguised beneath an accumulation of the insipid inventions of later times. At the same time they are not treated as mere tales for children, for Livy never forgets the dignity that belongs to them as the prelude to the great epic of Rome, and as consecrated by the faith of generations. Perhaps an even stronger proof of the skill which enabled Livy to avoid dangers which were fatal to weaker men is to be found in his speeches. We cannot indeed regard them, with the ancients, as the best part of his history, for the majority of them are obviously unhistorical, and nearly all savour somewhat too much of the rhetorical schools to be perfectly agreeable to modern taste. To appreciate them we must take them for what they are, pieces of declamation, intended either to enliven the course of the narrative, to place vividly before the reader the feelings and aims of the chief actors, or more frequently still to enforce some lesson which the author himself has at heart. The substance no doubt of many of them Livy took from his authorities, but their form is his own, and, in throwing into them all his own eloquence and enthusiasm, he not only acted in conformity with the established traditions of his art, but found a welcome outlet for feelings and ideas

which the fall of the republic had deprived of all other means of expression. To us, therefore, they are valuable not only for their eloquence, but still more as giving us our clearest insight into Livy's own sentiments, his lofty sense of the greatness of Rome, his appreciation of Roman courage and firmness, and his reverence for the simple virtues of older times. But, freely as Livy uses this privilege of speechmaking, his correct taste keeps his rhetoric within reasonable limits. With a very few exceptions the speeches are dignified in tone, full of life, and have at least a dramatic propriety, while of such incongruous and laboured absurdities as the speech which Dionysius puts into the mouth of Romulus, after the rape of the Sabine women, there are no instances in Livy.

But, if our estimate of the merits of his speeches is moderated by doubts as to his right to introduce them at all, no such scruples interfere with our admiration for the skill with which he has drawn the portraits of the great men who figure in his pages. We may indeed doubt whether in all cases they are drawn with perfect accuracy and impartiality, but of their life-like vigour and clearness there can be no question. With Livy this portrait-painting was a labour of love. "To all great men," says Seneca, "he gave their due ungrudgingly," but he is at his best in dealing with those who, like Q. Fabius Maximus, "the Delayer," were in his eyes the most perfect types of the true Roman. Over their pictures he lingers with loving care. Each act of their lives, and every speech that is put into their mouths, adds something to the completeness of the sketch, or brings into stronger relief its characteristic features, and thus the desired impression is produced more indelibly than by pages of critical analysis or panegyric.

The general effect of Livy's narrative is no doubt a little spoiled by the awkward arrangement, adopted from his authorities, which obliges him to group the events by years, and thus to disturb their natural relations and continuity. As the result his history has the appearance of being rather a series of brilliant pictures loosely strung together than a coherent narrative. But it is impossible not to admire the copious variety of thought and language, and the evenly flowing style which carried him safely through the dreariest periods of his history; and still more remarkable is the dramatic power he displays when some great crisis or thrilling episode stirs his blood. The sentences with which he begins his account of the sack of Rome by the Gauls are impressive in their solemn simplicity:—"In the same year one M. Cæcilius, a plebeian, gave notice to the tribunes that in the new road where now there standeth a chapel, above the temple of Vesta, there was in the still time of the night a voice heard, louder than any man's, commanding that the magistrates should be told that the Gauls were coming" (vi. 32). With genuine tragic irony he describes how, as the hour of their fate drew nigh, the minds of the Romans were blinded (vi. 37), and how they forgot their ancient cunning in counsel and their courage in the fight, till "full unhappily and in an ill hour" they were scattered by the winds by their foes. Equally vivid is his picture of the self-devotion of the senators who refused to save themselves by flight—"then the elders that had triumphed aforetime, and been consuls, openly gave out and said that they would live and die together with them." . . . But we have not space to follow the story to its triumphant close, when the banished Camillus arrived to save the country which had driven him into exile. Nor can we do more than refer to the description of the forced march of the consul Claudius in the Second Punic War, of the battle by the river Metaurus, and the death of Hannibal.

Livy, however, is not always at his best. For the full exercise of his powers he seems to require either the

stimulus supplied by the absorbing interest of the particular events he is describing, or the absence of any authority so full and so little to be disregarded as to fetter his freedom. Certain it is that in his accounts of the kingly period, and of the Hannibale war, he is seen to much better advantage than in the fourth and fifth decades. We may naturally suppose too that his energies flagged as the work progressed; and in the extant fragments of the unsteady first book other critics besides Niebuhr have detected the signs of failing strength.

In style and language Livy represents the best period of Latin prose writing. He has passed far beyond the bald and meagre diction of the early chroniclers. In his hands Latin acquired a flexibility and a richness of vocabulary unknown to it before. If he writes with less finish and a less perfect rhythm than his favourite model Cicero, he excels him in the varied structure of his periods, and their adaptation to the subject-matter. It is true that here and there the "creamy richness" of his style becomes verbosity, and that he occasionally draws too freely on his inexhaustible store of epithets, metaphors, and turns of speech, but these faults, which did not escape the censure even of friendly critics like Quintilian, are comparatively rare in the extant parts of his work. From the tendency to use a poetic diction in prose, which was so conspicuous a fault in the writers of the silver age, Livy is not wholly free. In his earlier books especially there are numerous phrases and sentences which have an unmistakably poetic ring, recalling sometimes Ennius and more often his contemporary Virgil (see for instance Teuffel, p. 482, n. 14). But in Livy this poetic element is kept within bounds, and serves only to give warmth and vividness to the narrative. Similarly, though the influence of rhetoric upon his language, as well as upon his general treatment, is clearly perceptible, he has not the perverted love of antithesis, paradox, and laboured word-painting which offends us in Tacitus, and, in spite of the Venetian richness of his colouring, and the opious flow of his words, he is on the whole wonderfully natural and simple.

These merits, not less than the high tone and easy grace of his narrative and the eloquence of his speeches, gave Livy a hold on Roman readers such as only Cicero and Virgil besides him ever obtained. His history formed the groundwork of nearly all that was afterwards written on the subject. Plutarch, writers on rhetoric like the elder Seneca, moralists like Valerius Maximus, went to Livy for their stock examples. Florus and Eutropius abridged him; Orosius extracted from him his proofs of the sinful blindness of the pagan world; and in every school Livy was firmly established as a text-book for the Roman youth.

By far the most complete account of the various editions of Livy, and of all that has been written upon him, will be found in Emil Hübner's *Grandes ou Fortissimes über die Römische Literaturgeschichte*, 4th ed., Berlin, 1878. The most successful translation of his history is that by Philemon Holland, London, 1600 (H. F. P.).

LIZARD. The name Lizard (Lat., *lacerta*) originally referred only to the small European species of four-legged reptiles, but is now applied to a whole order (*Lacertina*) which is represented by extremely numerous species in all temperate and tropical parts of the globe. Lizards may be described as reptiles with a more or less elongate body terminating in a tail, and with the skin either folded into scales (as in snakes) or granular or tubercular; legs are generally present—usually four, rarely two in number—but sometimes they are reduced to rudiments or entirely hidden below the skin; the jaws are toothed, and the two mandibles firmly united in front by an osseous suture. Eyelids are generally present. The vent is a transverse slit, and not longitudinal as in Crocodilina. Other structural characteristics, especially of the skeleton, separate lizards from the other orders of reptiles; but will be better

understood if described in relation to the other members of that class. See REPTILES.

At a low estimate the number of described species of lizards may be given as about one thousand seven hundred.¹ They are extremely scarce north of 60° N. lat.; and in the southern hemisphere the southern point of Patagonia forms the furthest limit of their range. As we approach the tropics, the variety of forms and the number of individuals increase steadily, the most specialized and the most developed forms (the monitors and leguans) being restricted to the tropical regions where lizards abound. They have adapted themselves to almost every physical condition, except the extreme cold of high latitudes or altitudes. Those inhabiting temperate latitudes hibernate. The majority live on broken ground, rocks with or without vegetation; others are arboreal; to a few (certain monitors) the neighbourhood of water is a necessity, whilst others are true desert animals, in colour scarcely distinguishable from their surroundings. Some, like many geckos, live near or in houses, being enabled by a peculiar apparatus of their toes to run along perpendicular and even overhanging surfaces. No lizard enters the sea, with the exception of one species, the leguan of the Galapagos (*Amphibolophis*), which feeds on sea-weed. Some, like the majority of the geckos, are nocturnal.

The motions of most lizards are executed with great but not enduring rapidity. With the exception of the chameleon, all drag their body over the ground, the limbs being wide apart, turned outwards, and relatively to the bulk of the body generally weak. But the limbs show with regard to development great variation, and an uninterrupted transition from the most perfect condition of two pairs with five separate clawed toes to their total disappearance; yet even limbless lizards retain rudiments of the osseous framework below the skin. The motions of these limbless lizards are very similar to those of snakes, which they resemble in their elongate body passing into a long cylindrical and tapering tail.

In a great many lizards (*Lacertina*, skinks, geckoes) the muscles of the several vertebral segments of the tail are so loosely connected, and the axis of the vertebrae is so weak, that the tail breaks off with the greatest facility. The part severed retains its muscular irritability for a short time, wriggling as if it were a living creature. A lizard thus mutilated does not seem to be much affected by its loss, and in a short time the part is reproduced; but, whilst the muscles and also the integuments may be perfectly regenerated, the osseous part always remains replaced by a cartilaginous rod, without vertebral segmentation. This faculty is of great advantage to the lizards endowed with it; they are either species in which the tail has no special function, such as to assist in a particular kind of locomotion or to serve as a weapon of defence, or they are small species which lack other means of escape from their numerous enemies. The geckoes are even able to throw off their tail spontaneously, and are said to do this frequently when pursued by some other animal, which is satisfied with capturing the wriggling member, whilst the owner saves its life by a rapid flight.

The majority of lizards are carnivorous, the larger feeding on small mammals, birds, fishes, and eggs, the smaller on insects, worms, and other invertebrates. Not a few, however, are herbivorous, as the larger leguans, and many agamas. This difference in diet is quite independent of modifications of dentition. Generally the teeth are simply

¹ The two latest general works on lizards are those by Duméril and Bibron (*Érpetologie générale*, with atlas, tom. i.-ix., Paris, 1844-54, 8vo), and by J. E. Gray (*Catalogue of Lizards in the Collection of the British Museum*, London, 1846, 8vo). Both are now antiquated, and a new edition of either is much required.

it is green, with minute blackish spots. In Germany and France one other species only (*Lacerta muralis*) appears, but in the south of Europe the species of *Lacerta* are much more numerous, the largest and finest being *L. ocellata*, which grows to a length of 18 or 20 inches, and is brilliantly green, ornamented with blue eye-like spots on the sides. Even the small island-rocks of the Mediterranean, sometimes only a few hundred yards in diameter, are occupied by peculiar races of lizards, which of late years have attracted much attention from the fact that they, like other reptiles, have assumed under such isolated conditions a more or less dark, almost black, coloration.

Moloderna horridum is a Mexican lizard, which in its native country has the reputation of being a most poisonous reptile. Its anterior teeth are, indeed, provided with a deep groove, as in many poisonous snakes, and the submaxillary gland is enormously developed. Sumichrast has recently proved by actual experiment on mammals the fatal effects of the bite of this lizard, and J. Stein, a traveller in Mexico, who was bitten in the finger, suffered from symptoms similar to those resulting from the bite of a poisonous snake. It thus appears that the fear in which it is held by the natives is not due merely to its hideous appearance, as was formerly believed. Tubercles of a dirty brown and yellow colour, with which its body is covered, give it the appearance of a leopards skin. It is about 20 inches long, and is known by the name of "Escorpion."

The Glass-Snake (*Pseudopus pallasi*) or *Sheltopussil* (Russ.) is common in Dalmatia, Hungary, southern Russia, and the western parts of Central Asia. Externally it resembles a snake, the fore limbs being entirely absent, and the hind limbs reduced to small rudiments. It attains to a length of 2 or 3 feet, and feeds on insects, worms, mice, and small birds. In captivity it becomes perfectly tame. North America is inhabited by a very similar glass-snake (*Ophisaurus*), and North Africa by a third (*Hyalosaurus*). Limbless lizards are especially common in Australia, but their scutellation is so different from that of the glass-snakes of the northern hemisphere that they are placed in distinct families, which have been noticed in the systematic list (*Pygopodidae*, *Aprasiidae*, *Uroliidae*).

The family of skinks also includes many genera with rudimentary limbs or without any, the Slow-Worm or Blind-Worm (*Anguis fragilis*) being the one most generally known. It is distributed over the greater part of Europe, and rarely exceeds a length of 15 inches. Its eyes, although small, are perfectly developed and provided with eyelids. It is oviparous, the young, in the first year of their life, differ considerably from the old in their coloration, the back being of a milk-white colour, with a black line down the middle. In the south of Europe it gradually disappears, and its place is taken by the similarly shaped *Seps*, a genus distinguished from *Anguis* by the presence of four very small rudiments of limbs, which have no function.

The Skink, which has given the name to the whole family, is a small lizard (*Scincus officinalis*) of 6 or 8 inches in length, common in arid districts of North Africa and Syria. A peculiarly wedge-shaped snout, and toes provided with strong fringes, enable this animal to burrow rapidly in and under the sand of the desert. In former times large quantities of it were imported in a dry state into Europe for official purposes, the drug having the reputation of being efficacious in diseases of the skin and lungs; and even now it may be found in apothecaries' shops in the south of Europe, country people regarding it as a powerful aphrodisiac for cattle.

Of the family *Iguanidae* we refer to three genera only—*Iguana*, *Anolis*, and *Phrynosoma*. Herpetologists distinguish several species of *Iguana* or *Leguans*, which, however, do not appear to differ in their habits. They are found in the forest regions of tropical America only, in the neighbourhood of water, into which when frightened they jump from the overhanging branches of trees, to escape capture by swimming and diving. Feeding ex-

FIG. 3.—Head of Leguana (*Iguana rhinolepoides*).

clusively on leaves or fruits, they are themselves highly esteemed as food, and their eggs also are eagerly searched for by the natives. Iguanas grow to a length of from 2 to 5 feet, and are readily recognized by a row of long compressed and pointed scales which form a more or less high crest along the middle of the back and tail, and by a compressed and pendant dewlap at the throat. These large lizards are strictly arboreal, and of a brilliant coloration, in which green prevails.

The smallest lizards of this family belong to the genus *Anolis*, extremely numerous as regards species and individuals on bushes and trees of tropical America, and especially of the West Indies. They offer many points of analogy to the humming birds in their distribution, colours, and even disposition. Gesse (*A Naturalist's Sojourn in Jamaica*, pp. 75 *sq.*) has given a vivid and faithful description of their manners. Hundreds may be seen on a bright day, sporting themselves on the trees and fences, leaping from branch to branch, fearlessly entering houses, chasing each other, or engaging in combat with some rival. Like the iguanas, they (at least the males) are provided with a large, expandable dewlap at the throat, which is brilliantly coloured, and which they display on the slightest provocation. This appendage is merely a fold of the skin, ornamental and sexual, like the wattles of the throat of a gallinaceous bird, it has no cavity in its interior, and has no communication with the mouth or with the respiratory organs; it is supported by the posterior horns of the hyoid bone, and can be erected and spread at the will of the animal. The presence of such dewlaps in lizards is always a sign of an excitable temper. The

anolis possess the power of changing their colours in a most extraordinary degree, the brilliant iridescent hues of their body passing almost in an instant into a dull sooty brown in an irritated or alarmed animal. They are much fed upon by birds and snakes, and have, like all small much-persecuted lizards, a fragile tail, easily reproduced. They bring forth only one large egg at a time, but probably breed several times during the season.

The third iguanoid, *Phrynosoma*, is a testaceous form. Several species are known, inhabiting the plains of southwestern America and Mexico. Since the opening of the Pacific Railway, living specimens are frequently sent to Europe, and sold under the name of "California toads." Although they belong to the same family, a greater contrast than that between the nimble, slender, and long-tailed *Anolis* and the toad-like *Phrynosoma* can hardly be imagined. The body is short, broad, and depressed, ending in a short tail, covered with rough tubercles or spines, the short head is armed behind with long bony spikes, the colours are a motley of brown, black, and yellow. Their defence against birds lies chiefly in their outward appearance, as, whilst they rest quiet, they are difficult to distinguish from a stone overgrown with lichen, nor have we ever found their remains in the stomach of snakes, their spines proving a sufficient protection against these equally formidable enemies. They are said to move with rapidity in a wild state, but in confinement, especially when the animal believes itself observed, their movements are extremely sluggish and their manners uninteresting. It seems to be a common belief in California that they have the power of squirting a blood-red fluid from the corner of the eye to some distance; but nothing has been found, on anatomical examination, to establish the correctness of this assertion. They attain a length of from 6 to 8 inches.

Of the *Iguanids*, which represent the iguanas in the Old World, and which have been differentiated into a still greater number of distinct generic forms, several genera deserve more than a merely nominal notice. The perhaps most highly specialized form are the Dragons (*Draco*), a genus of small lizards from the East Indies, more common in the archipelago than on the continent, but absent in Ceylon. The character by which they are at once recognized is the peculiar additional apparatus for locomotion, formed by the much-prolonged five or six hind ribs, which are connected by a broad expansible fold of the skin, the whole forming a subsemicircular wing on each side of the body. The snakes are the only order of vertebrates in which the ribs serve as organs of locomotion, but, whilst in that order all the ribs are charged with a function for which no other special organ exists, in the dragons only a part of the ribs are modified for the purpose of assisting four well-developed limbs. The dragons are tree-lizards, they take long flying leaps from branch to branch, supported in the air by their expanded parachutes, which are laid backwards at the side of the animal while it is sitting or merely running. If the hind or fore limbs of a dragon were cut off, it would be helpless, and deprived of locomotion, but it could continue to move with velocity after the loss of its wings. Like the anolis, whose analogues they are in the Old World, they are provided with long highly ornamented dewlaps. These appendages are found in both sexes, one in the middle and one on each side of the throat, but they are much more developed in the mature male. The tail is very long and slender, not fragile, we have never seen a dragon in which this member was mutilated, it seems to be necessary for their peculiar locomotion, and probably its loss soon proves fatal to the animal. Cantor says that the transcendent beauty of their colours baffles description.

As the lizard lies in the shade along the trunk of a tree, its colours at a distance appear as a mixture of brown and grey, and render it scarcely distinguishable from the bark. Thus it remains with no signs of life except the restless

FIG. 4.—Dragon (*Draco temminckii*).

eyes watching passing insects, which, suddenly expanding its wings, it seizes with a sometimes considerable unerring leap. All the species attain a length of 7 or 8 inches, of which the tail takes at least one half. They deposit three or four eggs at a time.

Calotes is another genus of agamoids peculiar to the East Indies; it comprises numerous species well known in India by the name of "blood-suckers," a designation the origin of which cannot satisfactorily be traced. They are tree-lizards, extremely variable in their colours, which change, not only with the season, but also at the will of the animal. The males, and in some species also the females, possess a crest of compressed scales along the back.

Of the Australian agamas no other genus is so numerously represented and widely distributed as *Grammatophora*, the species of which grow to a length of from 8 to 18 inches. Their scales are generally rough and spinous, but otherwise they possess no strikingly distinguishing peculiarity, unless the loose skin of their throat, which is transversely folded and capable of inflation, be regarded as such. On the other hand, two other Australian agamoids have attained some celebrity by their grotesque appearance, due to the extraordinary development of their integuments. One (fig. 5) is the Frilled Lizard (*Chlamydosaurus*), which is restricted to Queensland and the north coast, and grows to a length of 2 feet, including the long tapering tail. It is provided with a frill-like fold of the skin round the neck, which, when erected, resembles a broad collar, not unlike the gigantic lace-collars of Queen

Elizabeth's time. The late Mr Krefft has made the observation that this lizard when startled, rises with the forelegs off the ground, and squats and jumps in kangaroo-fashion, thus reminding us of the peculiar locomotion ascribed to certain gigantic extinct reptiles. The other lizard is one which most appropriately has been called

FIG 5.—Filled Lizard (*Chlamydosaurus kingi*)

Moloch horridus. It is covered with large and small spine-bearing tubercles; the head is small, and the tail short. It is sluggish in its movements, and so harmless that its armature and (to a casual observer) repulsive appearance are its sole means of defence. It grows only to a length of 10 inches, and is not uncommon in the flats of South and West Australia.

The majority of the ground-agamas, and the most common species of the plains, deserts, or rocky districts of Africa and Asia, belong to the genera *Stellio* and *Agama*. They resemble much the *Grammatophora* of the Australian region, their scales being mixed with larger prominent spines, which in some species are particularly developed on the tail, and disposed in whorls. Nearly all travellers in the north of Africa mention the *Hardibia* of the Atabs (*Stellio cordylus*), which is extremely common, and has drawn upon itself the hatred of the Mohammedans by its habit of nodding its head, which they interpret as a mockery of their own movements whilst engaged in prayer. *Uromastix* is one of the largest and most developed genera of ground-agamas, and likewise found in Africa and Asia. The body is uniformly covered with granular scales, whilst the short, strong tail is armed with powerful spines disposed in whorls. The Indian species (*U. hardwickii*) feeds on herbs only; the African species probably take mixed food.

The Chameleons are almost peculiar to the African region, and most numerous in Madagascar, where out of the thirty-six species known not less than seventeen occur. Only one species (*C. virgatus*) extends into India and Ceylon. No other member of the order of lizards shows such a degree of specialization as the chameleons. The tongue, eyes, limbs, tail, skin, lungs are modified in a most extraordinary manner to serve special functions in the peculiar economy of these animals. They lead an exclusively arboreal life, each of their feet is converted into a grasping

hand, by means of which, assisted by a long prehensile tail, they hold so fast to a branch on which they are sitting that they can only with difficulty be dislodged. Their movements are slow on the ground, and still more so in the water, where they are nearly helpless. As in ant-eaters, woodpeckers, or frogs, their tongue is the organ with which they catch their prey, it is exceedingly long, worm-like, with a club-shaped viscid end, they shoot it out of the mouth with incredible rapidity towards insects, which remain attached to it, and are thus caught. The globular eyes are

FIG 6.—Front foot of *Chamaeleon chamaeleon*

covered with a circular lid pierced by a small central hole, and are so prominent that more than one-half of the ball stands out of the head. Not only can they be moved in any direction, but each has an action independent of the other, one eye may be looking forwards, whilst an object behind the animal is examined with the other. The lungs of the chameleons are very capacious, and are inflated when the animal is angry or frightened. The faculty of changing colour, which they have in common with many other lizards, is partly dependent on the degree in which the lungs are filled with air, and different layers of chromatophores are pressed towards the outer surface of the skin. Some species are only a few inches long, whilst others attain to a length of 18 and 20 inches. The majority are oviparous, a few ovoviviparous.

Almost all the lizards belonging to the family of *Gekkos* may be recognised at first sight, the head is broad and depressed, the eyes large, the body depressed; the tail is thick at the base, tapering, generally somewhat deformed, as a specimen is rarely met with in which this member is not reproduced. The limbs are stout, rather short, with at least four of the toes well developed. *Gekkos* are found in almost every part of the globe between and near the tropics, frequenting houses, rocks, and trees; and some of the species are so numerous around and within human dwellings as to be most familiar objects to the inhabitants. Many are able

to run up and along the largest vertical surface of a wall or of any other perpendicular object, for this purpose the lower surface of their toes is provided with a series of movable plates or disks,¹ by the aid of which they adhere to the surface over which they pass. In forest-species this apparatus is generally less developed, or entirely absent, claws being of greater use for walking up the rough bark of a tree. *Gekkos*, with few exceptions, are nocturnal and, consequently, large-eyed animals, the pupil being generally contracted in a vertical direction, shaped like two rhombi placed with the angles towards each other. They are of small size, the largest species not exceeding 10 or 14 inches in length. They are carnivorous, destroying moths and all kinds of insects, and even the younger and weaker members of their own species. They have been seen devouring the skin which they cast off, and

¹ The mechanism resembles in some the adhesive organ of *Echinos* or sucking-fish, in others that of the legs of a fly.

their own wriggling tail. They are of a fierce disposition, frequently fighting among themselves, but house-geckos readily become habituated to the presence of man, occasionally to be fed at a certain time with rice, these little lizards will punctually make their appearance, and fearlessly take the proffered food. Another peculiarity of geckos is that they, or at least some genera, are endowed with a voice. The large *Gekko guttatus* and *G. monachus* of the East Indies utter a shrill cry, sounding like "toke" or "tok." The common species found in houses in the south of Europe are a species of *Hemidactylus* (*H. variegatus*) and *Tarentola*, the *terrentola* of the Italians. All geckos seem to be oviparous. (A C G)

LLAMA, sometimes spelt *Lama*, a word by which the Peruvians designated one of a small group of closely allied animals, which, before the Spanish conquest of America, were the only domesticated hoofed mammals of the country, being kept, not only for their value as beasts of burden, but also for their flesh, hides, and wool,—in fact, supplying in the domestic economy of the people the place of the horse, the ox, the goat, and the sheep of the Old World. The word is now sometimes restricted to one particular species or variety of the group, and sometimes used in a generic sense to cover the whole. Although they were often compared by early writers to sheep, and spoken of as such, their affinity to the camel was very soon perceived, and they were included in the genus *Camelus* in the *Systema Naturæ* of Linnaeus. They were, however, separated by Cuvier in 1800 under the name of *Lama*, changed by Illiger in 1811 to *Acridonta* (in allusion to the great length of neck, *ακρίς*), a term afterwards adopted by Cuvier, and almost universally accepted by systematic zoologists, although there has been of late a disposition to revive the earlier name.

The animals of the genus *Auchenia* or *Lama* are, with the two species of true camels (to which the generic term *Camelus* is now restricted), the sole existing representatives of a very distinct section of the "artiodactyle" or even-

FIG. 1.—Llama (from an animal living in the Gardens of the Zoological Society of London)

toed ungulates, called *Tylopoda*, or "boss-footed," from the peculiar bosses or cushions placed on the under surface of their feet, and on which they tread. This section thus consists of a single family, the *Camelidae*, the other sections of the same great division being the *Stomax* or pigs,

the *Tragulina* or chevrotains, and the *Pecora* or true ruminants, to each of which the *Tylopoda* have more or less affinity, standing in some respects in a central position between them, borrowing as it were some characters from each, but in others showing great special modifications not found in any of the other sections.

Until within the last few years the existence of two genera having so very much in common as the camels and the llamas, and yet so completely isolated geographically, had not received any satisfactory explanation, for the old idea that they in some way "represented" each other in the two hemispheres of the world was a mere fancy without philosophical basis. The discoveries made mostly within the past ten years of a vast and previously unsuspected extinct fauna of the American continent of the Tertiary period, as interpreted by the able paleontologists Leidy, Cope, and Marsh, has thrown a flood of light upon the early history of this family, and upon its relations to other mammals. It is now known that llamas at one time were not confined to the part of the continent south of the Isthmus of Panama, as at the present day, for their remains have been abundantly found in the Pleistocene deposits of the region of the Rocky Mountains, and in Central America, some attaining a much larger size than those now existing. There have also been found in the same regions many camel-like animals exhibiting different generic modifications, and, what is more interesting, a gradual series of changes, coinciding with the antiquity of the deposits in which they are found, have been traced from the thoroughly differentiated species of the modern epoch down through the Pliocene to the early Miocene beds, where, their characters having become by degrees more generalized, they have lost all that especially distinguishes them as *Camelidae*, and are merged into forms common to the ancestral type of all the other sections of the Artiodactyles. Hitherto none of these ancestral forms have been found in any of the fossiliferous strata of the Old World, it may therefore be fairly surmised (according to the evidence at present before us) that America was the original home of the *Tylopoda*, and that the true camels have passed over into the Old World, probably by way of the north of Asia, where we have every reason to believe there was formerly a free communication between the continents, and then, gradually driven southward, perhaps by changes of climate, having become isolated, have undergone some further special modifications; while those members of the family that remained in their original birthplace have become, through causes not clearly understood, restricted solely to the southern or most distant part of the continent. There are few groups of mammals of which the paleontological history has been so satisfactorily demonstrated as the one of which we are treating.¹

The special characters which the llamas and camels have in common, and the combination of which distinguishes them from the rest of the Artiodactyles, are as follows. The premaxillæ have the full number of incisor teeth in the young state, and the outermost is permanent through life, an isolated lunulariform tooth. The canines are present in both jaws, and those of the mandible are differentiated from the long, procumbent, and spatulate incisors, being suberect and pointed. The crowns of the true molars belong to the "selenodont" type, and are very long or "hypselodont"; but one or more of the anterior premolars is usually detached from the series, and of simple pointed form. The hinder part of the body is much contracted, and the femur long and vertically placed, so that the knee-joint is lower in position, and the thigh altogether more detached from the abdomen than in most quadrupedal mammals. The limbs are long, but with only two digits (the third and fourth) developed on each, no traces of any of the others being present. The trapezoid and magnum of the carpus, and the cuboid and navicular of the tarsus are distinct. The two metatarsal bones of each limb are confluent for the greater part of their length, though

¹ See especially E. D. Cope, in Wheeler's *Report of the Survey West of the 100th Meridian*, iv. pt. 2, pp. 325-46, 1877.

separated for a considerable distance at the lower end. Then distal articular surfaces, instead of being pulley-like, with deep ridges and grooves, as in other Artiodactyls, are simple, rounded, and smooth. The proximal phalanges are expanded at their distal ends, and the wide, depressed middle phalanges are embedded in a broad cutaneous pad, forming the sole of the foot, on which the animal rests in walking instead of on the hoofs. The ungual phalanges are very small and nodular, not flattened on their inner or opposed surfaces, and not completely encased in hoofs, but bearing nails on their upper surface only. The cervical region is long and fleshy, and the vertebrae of which it is composed are remarkable for the position of the canal for the transmission of the vertebral artery, which does not perforate the transverse process, but passes obliquely through the anterior part of the pedicle of the arch (a condition only found in two other genera of mammals, *Macrauchenius* and *Myrdocophaga*). There are no horns or antlers. Though these animals ruminate, the stomach differs considerably in the details of its construction from that of the *Pecora*. The interior of the rumen or paunch has no villi on its surface, and there is no distinct pyloricum or rumen. Both first and second compartments are remarkable for the presence of a number of pouches or cells in their walls, with muscular septa, and a sphincter-like arrangement of their orifices, by which they can be shut off from the rest of the organ, and into which the fluid portion only of the contents of the stomach is allowed to enter. The placenta is diffuse as in the *Simia* and *Tragulina*, not cotyledonary as in the *Pecora*. Finally, they differ not only from other ungulates, but from all other mammals, in the fact that the red corpuscles of the blood, instead of being circular in outline, are oval as in the inferior vertebrate classes.

The following characters apply especially to the llamas. Dentition of adults—maxillars 2, canines 3, premolars 3, molars 3, total 82. In the upper jaw there is a compressed, sharp, pointed laminiiform incisor near the hinder edge of the premaxilla, followed in the male sex by a minute, sharp, pointed, curved two-cuspid in the anterior part of the maxilla. The isolated canine-like molar which follows in the canine is not present. The teeth of the molar series which are in contact with each other consist of two very small premolars (the first almost rudimentary) and three broad molars, constructed generally like those of the lower jaw, the third molar being the most and longest, spatulate, and procumbent; the outer ones are the smallest. Next to these is a curved, suberect canine, followed after an interval by an isolated minute and often deciduous simple conical premolar, then a contiguous series of one premolar and three molars, which differ from those of *Camelus* in having a small accessory column at the anterior outer edge. The skull generally resembles that of *Camelus*, the relatively larger brain-cavity and orbits and less developed cranial ridges being due to its smaller size. The nasal bones are shorter and broader, and are joined by the premaxilla. Vertebrae cervical 7, dorsal 12, lumbar 7, sacral 4, caudal 15 to 20. Ears rather long and pointed. No dorsal hump. Feet narrow, the toes being more separated than in the camels, each having a distinct plantar pad. Tail short. Hairy covering long and woolly. Size smaller and general form lighter than in the camels. At present and within historic times they are entirely confined to the western side and southernmost parts of South America, though fossil remains have been found in the caves of Brazil, in the pampas of the Argentine republic, and, as before mentioned, in Central and North America.

In essential structural characters, as well as in general appearance and habits, all the animals of this genus very closely resemble each other, so that the question as to whether they should be considered as belonging to one, two, or more species has been one which has led to a large amount of controversy among naturalists. The question has been much complicated by the circumstance of the great majority of individuals which have come under observation being either in a completely or partially domesticated state, and descended from ancestors which from time immemorial have been in like condition, one which always tends to produce a certain amount of variation from the original type. It has, however, lost much of its import-

ance since the doctrine of the distinct origin of species has been generally abandoned. The four forms commonly distinguished by the inhabitants of South America are recognized by some naturalists as distinct species, and have had specific designations attached to them, though usually with expressions of doubt, and with great difficulties in defining their distinctive characteristics. These are—(1) the llama, *Aschelus glama* (Linn.), or *Lama peruanus* (Niedemann); (2) the alpaca, *A. pacos* (Linn.), (3) the guanaco or huanoaco, *A. huanaco* (Molina), and (4) the vicugna, *A. vicugna* (Molina), or *A. vicugna*, (Cuv.) The first and second are only known in the domestic state, and are variable in size and colour, being often white, black, or piebald. The third and fourth are wild, and of a nearly uniform light-brown colour, passing into white below. They certainly differ from each other, the vicugna being

smaller, more slender, and having a shorter head than the guanaco. It may, therefore, according to the usual view of species, be considered distinct. It lives in herds on the bleak and elevated parts of the mountain range bordering the region of perpetual snow, amid steep rocks and precipices, occurring in various suitable localities throughout Peru, in the southern part of Ecuador, and as far south as the middle of Bolivia. Its manners very much resemble those of the chamois of the European Alps; and it is as vigilant, wild, and timid. The wool is extremely delicate and soft, and highly valued for the purposes of weaving, but the quantity which each animal produces is not great.

The guanaco has an extensive geographical range, from the high lands of the Andean region of Ecuador and Peru to the open plains of Patagonia, and even the wooded islands of Tierra del Fuego. It constitutes the principal food of the Patagonian Indians, and its skin is invaluable to them, as furnishing the material out of which their long robes are constructed. It is about the size of a European red deer, and is an elegant animal, being possessed of a long, slender, gracefully curved neck and fine legs. Dr Cunningham,* speaking from observation on wild animals, says—

* The stomach of the camel inhabiting the Arabian desert is commonly looked upon as a striking example of specialized structure, adapted or modified in direct accordance with a highly specialized mode of life, it is therefore very remarkable to find an organ exactly similar, except in some unessential details, in the llamas of the Peruvian Andes and the guanacos of the Pampas. No hypothesis except that of a common origin will satisfactorily account for this, and, granting that this view is correct, it becomes extremely interesting to find for how long a time two genera may be isolated and yet retain such close similarities in parts which in other groups appear readily subject to adaptive modifications.

* Natural History of the Strait of Magellan, 1871

"It is not easy to describe its general appearance, which combines some of the characters of a camel, a deer and a goat. The body, deep at the breast but very small at the loins, is covered with long, soft, very fine hair, which on the upper parts is of a kind of fawn-colour, and beneath varies from a very pale yellow to the most beautiful snow-white. The head is provided with large ears, in general carried well back, and is covered with short greyish hair, which is darkest on the forehead. Occasionally the face is awfully black. As a rule, it lives in flocks of from half a dozen to several hundreds, but solitary individuals are now and then to be met with. They are very difficult to approach sufficiently near to admit of an easy shot, as they are extremely wary, but, on being disturbed, cower off at a pace which soon puts a safe distance between them and the sportsman, even though he should be mounted. Despite their timidity, however, they are possessed of great curiosity, and will sometimes advance within a comparatively short distance of an unknown object, at which they will gaze fixedly till they take alarm, when they effect a speedy retreat. Their cry is very peculiar, being something between the belling of a deer and the neigh of a horse. It would be difficult to overestimate their numbers upon the Patagonian plains, for in whatever direction we walked we always came upon numbers of portions of their skeletons and detached bones."

Darwin, who has given a most interesting account of the habits of the guanaco in his *Naturalist's Voyage*, says that they readily take to the water, and were seen several times at Port Valdes swimming from island to island.

The llama is only known as a domestic animal, and is chiefly met with in the southern part of Peru. Burmeister, the latest and a very competent writer on the subject,¹ says that he is perfectly satisfied that it is the descendant of the wild guanaco, an opinion opposed to that of Tschudi. It generally attains a larger size than the guanaco, and is usually white or spotted with brown or black, and sometimes altogether black. The earliest and often quoted account of this animal by Augustin de Zarate, treasurer-general of Peru in 1544, will bear repeating as an excellent summary of the general character and uses to which it was put by the Peruvians at the time of the Spanish conquest. He speaks of the llama as a sheep, observing, however, that it is camel-like in shape, though destitute of a hump:—

"In places where there is no snow, the natives want water, and to supply this they fill the skins of sheep with water and make other living sheep carry them, for, it must be remarked, those sheep of Peru are large enough to serve as beasts of burden. They can carry about one hundred pounds or more, and the Spaniards used to ride them, and they would go four or five leagues a day. When they are weary they lie down upon the ground, and as there are no means of making them get up, either by beating or seating them, the lord must of necessity be taken off. When there is a man on one of them, if the beast is tired and urged to go on, he turns his head round, and discharges his saliva, which has an unpleasant odour, into the ruler's face. These animals are of great use and profit to their masters, for their wool is very good and fine, particularly that of the species called paca, which have very long fleeces, and the expense of their food is trifling, as a handful of maize suffices them, and they can go four or five days without water. Their flesh is as good as that of the fat sheep of Castile. There are now public shambles for the sale of their flesh in all parts of Peru, which was not the case when the Spaniards came first, for when an Indian had killed a sheep his neighbours came and took what they wanted, and then another Indian killed a sheep in his turn."

The disagreeable habit here noticed of spitting in the face of persons whose presence is obnoxious is common to all the group, as may be daily witnessed in specimens in confinement in the menageries of Europe. One of the principal labours to which the llamas were subjected at the time of the Spanish conquest was that of bringing down ore from the mines in the mountains. Gregory de Bolivar estimated that in his day as many as three hundred thousand were employed in the transport of the produce of the mines of Potosi alone, but since the introduction of horses, mules, and donkeys the importance of the llama as a beast of burden has greatly diminished.

The alpaca is believed by most naturalists to be a variety of the vicugna; others have, however, identified it with the guanaco, and some consider it as a distinct species. It is usually found in a domesticated or semi-domesticated state, being kept in large flocks which graze on the level heights of the Andes of southern Peru and northern Bolivia at an elevation of from 14,000 to 16,000 feet above the sea-level, throughout the year. It is not used as a beast of burden like the llama, but is valued only for its wool, of which the Indian blankets and ponchos are made. Its colour is usually dark brown or black. The characteristics of its wool, and the history of its introduction into British manufacturing industry, are described in the article ALPACA. (W. H. R.)

LLANDAFF, a city of Glamorgan, South Wales. See CARDIFF, within which parliamentary borough it is almost entirely included.

LLANDUDNO, a watering-place in Carnarvonshire, North Wales, situated on the Irish Sea, and at the mouth of the Conway, in a finely sheltered bay, 50 miles west of Chester by rail. It lies between Great Orme's Head and Little Orme's Head, two lofty promontories which rise precipitously from the sea to the height of several hundred feet. Round Great Orme's Head a public drive has been made, from which very picturesque views are obtained. The rock is greatly frequented by many varieties of sea birds, and is also the habitat of many rare plants. The old parish church of St Tudno, situated on a cliff overlooking the sea, has been replaced by a later structure (St George's), and the Church of Holy Trinity in the First Pointed style was erected in 1865. The chief attractions of the town are its picturesque and sheltered situation, and the fine facilities it affords for sea bathing. In the neighbouring coppice-mires various mineralogical specimens of interest have been found. On the summit of the head there are the remains of old circular buildings, some portions of an old fortress, and a rocking stone. The population of the urban sanitary district in 1871 was 2732, and in 1881 it was 4883, but these figures do not represent its summer population, which is nearly twice as great.

LLANELLY, a market-town, parliamentary borough, and seaport town of Carmarthenshire, South Wales, is situated on a creek of Carmarthen Bay, on the river Loughor, and on several railway lines, 11 miles west of Swansea, and 225 west-north-west of London. It is a prosperous manufacturing town. The church of St Elli or Llanelly is in the Early English style, with a square embattled tower. The other principal buildings are the town-hall and the Athenaeum. The town possesses extensive docks. It imports large quantities of copper ore, and carries on an export trade in its special manufactures. For the last five years the exports have averaged above £150,000 annually, and the imports £50,000. There are copper, silver, lead, and tin works, iron foundries, manufactures of pottery, chemical works, brick and tile works, flour-mills, and breweries; and in the vicinity there are extensive collieries. Llanelly is included in the Carmarthen district of parliamentary boroughs. The population of the urban sanitary district in 1871 was 14,973, which in 1881 had increased to 19,655.

LLANGOLLEN, a picturesque market-town of Denbighshire, North Wales, and a favourite summer resort, is beautifully situated in a fine vale surrounded by lofty mountains, on the right bank of the Dee, and on a branch line of the Great Western Railway, 9 miles south-west of Wrexham, and 22 south-west of Chester. The river is crossed by a peculiarly constructed bridge of five arches built in 1345. The church, dedicated to St Collen, is a plain but ancient structure, partly in the Early English style. Opposite the town, on the summit of a conical hill,

¹ *Description Physique de la République Argentine*, vol. iii p. 468, 1879.

are the remains of a very ancient fortress, the Castell Dinas Brán. The beautiful abbey of Valle Crucis, in a neighbouring dell, is one of the finest ecclesiastical ruins in Wales. Near it there is an ancient British monument, the "Pillar of Eliseg." The principal secular buildings of the town are the town-hall and the court-house. The industries include the manufacture of linen and wool, and in the vicinity there are collieries, lime-works, and iron-works. The population of the urban sanitary district in 1871 was 2798, and in 1881 it was 3124.

LORENTE, JUAN ANTONIO (1756-1823), the historian of the Spanish Inquisition, was born March 30, 1756, at Lunco de Soto, near Calahorra, Aragon, studied at Tarragona and Saragossa, received (by dispensation) priest's orders in 1779, and became vicar-general to the bishop of Calahorra in 1782. In 1785 he became commissary of the Holy Office at Logroño, and in 1789 its general secretary at Madrid. In 1805 he obtained a canonry at Toledo, and in 1805-8 his *Noticias Históricas sobre las tres Provincias Vascongadas* appeared. In the crisis of 1808 Llorente identified himself with the Bonapartists, and from 1809 onwards he was engaged in superintending the execution of the decree of suppression of the monastic orders, and in examining the archives of the Inquisition for his *History*, a work which appeared in 1817-18 at Paris, where its author had been residing since the return of Ferdinand VII. to Madrid in 1814, under the title *Histoire critique de l'Inquisition d'Espagne, depuis l'époque de son établissement par Ferdinand V. jusqu'au règne de Ferdinand VII., tirée des pièces originales du Conseil de la Suprême et de celles des tribunaux subalternes du Saint Office*. Translated within a few years into German, English, Dutch, Italian, and Spanish, it attracted much attention throughout Europe, and involved its author in considerable persecution and hardship, which, on the publication of his *Portraits politiques des Papes* in 1822, culminated in a peremptory order (December 1822) to quit France. His death, caused, or at least hastened, by the fatigues of the hasty journey to Spain, took place at Madrid on February 5, 1823. Both the personal character and the literary trustworthiness of Llorente have been very bitterly assailed; but, although he was very imperfectly equipped as an exact historian, there is no reason to doubt that he made an honest use of documents (now no longer extant) relating to the Inquisition, to which he had access at Madrid. An English (abridged) translation of the *History* appeared in 1826. A full list of the numerous writings of Llorente is given in the *Biographie Générale*.

LLOYDS, an association of merchants, shipowners, underwriters, and ship and insurance brokers, having its headquarters in a suite of rooms in the north-east corner of the Royal Exchange, London. Originally a mere gathering of merchants for business or gossip in a coffee-house kept by one Edward Lloyd in Tower Street, London, the earliest notice of which occurs in the *London Gazette* of 18th February 1688, this institution has gradually become one of the greatest and most perfect organizations in the world in connexion with commerce. The establishment existed in Tower Street up to 1692, in which year it was removed by the enterprising proprietor to Lombard Street, in the very centre of that portion of the old city of London most frequented by merchants of the highest class. Shortly after this event Mr Lloyd gave another proof of his enterprise and intelligence by the establishment of a weekly newspaper furnishing commercial and shipping news, in those days an undertaking of no small difficulty. This paper took the name of *Lloyd's News*, and, though its life was not a prolonged one, it was destined to be the precursor of the now ubiquitous *Lloyd's List*, the oldest existing paper, the *London Gazette* excepted, of the present

day. In Lombard Street the business transacted at Lloyd's coffee-houses steadily grew in extent and importance, but it does not appear that throughout the greater part of the 18th century the merchants and underwriters frequenting the rooms were bound together by any rules, or acted under any organization. By and by, however, the rapid increase of marine insurance business made a change of system and improved accommodation absolutely necessary, and accordingly, after finding a temporary resting-place in Pope's Head Alley, the underwriters and brokers finally settled down in the Royal Exchange in March 1774. One of the first improvements in the mode of effecting marine insurance springing out of this new state of things was the introduction of a printed form of policy. Hitherto various forms had been in use; and, to avoid the numerous disputes consequent on a practice so loose and unsatisfactory, the committee of Lloyd's proposed a general form, which was finally adopted by the members on the 12th of January 1779, and which remains in use, with only a few slight alterations, to this day. The two most important events in the history of Lloyd's during the present century are the reorganization of the association in 1811, and the passage of an Act in 1871 granting to Lloyd's all the rights and privileges of a corporation sanctioned by parliament. According to this Act of Incorporation, the three main objects for which the society exists are—first, the carrying out of the business of marine insurance, secondly, the protection of the interests of the members of the association; and thirdly, the collection, publication, and diffusion of intelligence and information with respect to shipping. In the promotion of the last-named object, obviously the foundation upon which the entire superstructure rests, an intelligence department has been gradually developed which for wideness of range and efficient working has no parallel among private enterprises in any country.

The rooms at Lloyd's are available only to subscribers and members. The former pay an annual subscription of five guineas without entrance fee, but have no voice in the management of the institution. The latter consist of non-underwriting members, who pay an entrance fee of twelve guineas, and of underwriting members, who pay a fee of one hundred pounds. Underwriting members are also required to deposit securities to the value of £5000 to £10,000, according to circumstances, as a guarantee for their engagements. The management of the establishment is delegated by the members to certain of their number selected as a "committee for managing the affairs of Lloyd's." With this body lies the appointment of all the officials and agents of the institution, the daily routine of duty being entrusted to a secretary and a large staff of clerks and other assistants. The mode employed in effecting an insurance at Lloyd's is very simple. The business is done entirely by brokers, who write upon a slip of paper the name of the ship and shipmaster, the nature of the voyage, the subject to be insured, and the amount at which it is valued. If the risk is accepted, each underwriter subscribes his name and the amount he agrees to take or underwrite, the insurance being effected as soon as the total value is made up. The sum paid by the insured to the underwriters is denominated the premium, a tax upon the profits of the merchant which the progress of science, of the art of shipbuilding, and of navigation has in these days reduced to a very moderate figure. (W. P. H.)

LOACH. The loaches (*Cobitidae*) are small fishes of the Carp family (*Cyprinidae*), with a generally cylindrical body, with very small or without any scales, with six or more barbels round the mouth, with a short dorsal and anal fin, and with the pharyngeal teeth in a single series. The air-bladder is double, as in other carps, the two divisions lying side by side, or one behind the other; but

it is always entirely or partially enclosed in a bony capsule formed by the anterior vertebra. The largest of the ninety species known grow to a length of 10 or 12 inches, but the majority are of much smaller dimensions. They are found in Europe and Asia only. The typical species are partial to fast-running streams with stony bottoms; they abound in the waters draining the central Alps of Asia, and extend far towards the north of the Euro-Asiatic region. The tropical forms from south of the Himalayas are not less common, and some of them have assumed a more compressed form of the body with a bright coloration. In Great Britain two species occur, viz., the common loach (*Nemachilus barbatulus*), and the more local *Cobitis taenia*, which is distinguished by a small spine below the eye. The former is esteemed as food in parts of the Continent where it occurs in sufficient abundance. See ICHTHYOLOGY.

LOANDA, or in full São Paulo de Loanda, the capital of the Portuguese settlements in western Africa, and the principal municipality of the Loanda district, one of the three into which Angola is divided, is situated on the mainland in 8° 48' S. lat. and 13° 7' E. long. The beautiful bay, protected from the surf by the long narrow island of pure sand from which the town takes its name, is backed by a line of low sandy cliff which at its southern end sweeps out with a sharp curve and terminates in the bold point crowned by Fort San Miguel. A good part of the town lies on the shore, but the more important buildings—the Government offices, the governor's residence, the palace of the bishop of Angola, and the admirable hospital—are situated on the higher grounds. Most of the European houses are large stone buildings of one story with red tile roofs. The streets, formerly full of loose fine sand, have in many cases been paved. The great defect of the situation is the want of water, which had to be brought for the most part in little boats from the Bengo and the Dande; but the Portuguese Government signed a contract in November 1877, by which a canal 4½ miles long was to be constructed, at a cost of 6,000,000 francs, from Tãdã-bondo (a point 37 miles from the mouth of the Bengo) to the city. Loanda is a busy place; the shops are well supplied with European goods, and large native markets are held in various parts of the town. While the slave trade to Brazil was still in full prosperity, the traffic of the port was of no small account; and after a period of great depression it is now developing in more legitimate directions. There is a regular service of steamers from Lisbon and Liverpool, and in 1877 746 vessels entered and 693 cleared. The population is from 10,000 to 12,000 (Lux gives 18,000 to 20,000), about a third being whites. From 1641 to 1648 Loanda was occupied by the Dutch.

See J. J. Monteiro, *Angola and the River Congo*, London, 1876; and Lux, *Von Loanda nach Kilmindani*, Vienna, 1880.

LOANGO, in the wider signification of the name, is a region on the west coast of southern Africa, which extends from the mouth of the Congo (Zaire) river in 6° S. lat. northwards through about two degrees, with no very definite limit in this direction, unless we adopt the Numbi river which falls into Chilunga Bay in 4° 9' S. lat., and was formerly considered the northern boundary of the Loango kingdom. In a narrower sense it is the country bounded on the S. by the Luemua, and on the N. by the Kuilu,—the district between the Luemua and the Chiloango being known as Chiloango or Little Loango, that between the Chiloango and the Congo as Kakongo and Angoy, and that to the north of the Kuilu as Chilunga. The whole country between 6° and 4° may be described as the lowland portion of the seaward versant of the Serra do Oyatal or Serra Complida, a range running almost parallel with the coast, from which its spurs and underfalls are distant only

30 or 40 miles. It has an irregularly undulating or hilly surface, slowly rising in somewhat indadute terraces, and is traversed from north-east to south-west by a number of considerable streams flowing in well-marked valleys. The coast-line in some stretches is low and swampy, while in others, as along Loango and Kabunda Bays, it presents a series of cliffs 40 to 50 feet high. Behind the region of alluvial deposits which prevails for some distance inland there is a broken belt of Tertiary rocks; but these soon give place to laterite, and beyond the laterite lie the mica-schists, talcs, and gneiss of which the mountains are composed. Of the Loango rivers the best explored is the Kuilu or Quilu. At its mouth, in 4° 29' S. lat., it is a noble stream 1100 feet wide, but the bar has hitherto proved an insuperable obstacle to the entrance of sea-going ships; near the Mayombe factory, which may be reached in fifteen hours from the coast, it begins to take the character of a mountain stream. Its principal affluent is the Nanga. Farther south are the Songolo and the Luemua. Of greater importance as a navigable route towards the interior is the Chiloango or Loango Luse (sometimes erroneously called the Kakongo), which disembores in 5° 12' S. lat. and 12° 6' E. long., and is formed about 15 miles inland by the junction of the Loango and the Lukulu, of which the one separates Loango proper from the Osobo country and the other the Osobo country from Kakongo.

Though a large proportion of the Loango coast region is occupied by primeval forest, with trees rising to a height of 150 and 200 feet, there is considerable variety of scenery—open lagoons, mangrove swamps, scattered clusters of trees, park-like regions, grassy well-watered underwood along the rivers, prairies of tall grass through which no pathway can be driven, and patches of cultivation. Among the more characteristic forms of vegetation are baobabs, silk-cotton trees, screw-pines, and palms—especially *Hyphene guineensis* (a fan-palm), *Raphia* (the wine-palm), and *Elms guineensis* (the oil-palm). Anomalous plants (only a few of which are the *palmdendrons*, an olive-myrtle-like tree, are common in the prairies, the papyrus shoots up to a height of 30 feet along the rivers (particularly the Luemua); the banks are fringed by the cottony *Hibiscus tiliaceus*, ipomoeas, and flagrant jasmains; and the thickets are bound together in one inextricable mass by a growth of many kinds. Among the fruit trees are the mango and the papaya, the orange has been successfully introduced at Vista and Kabunda, and the lemon continues to flourish well up the country. Negro-pepper (a variety of capsicum) and ginger grow wild, the natives, in addition to manioc (their staple sustenance) and bananas, cultivate groundnuts and tobacco; and the planters have European vegetables in their gardens.

The crocodile, the hippopotamus, and several kinds of apes—including the chimpanzee and the rare gorilla—are the most noteworthy larger animals, the birds are various and beautiful—gray parrots, shrikes, fly-catchers, rufous-colored birds, waver birds (seen in large colonies on the palm-trees), ice-birds, from the *Ceryle Sharpei* to the dwarfish *Alcedo cristata*, butterfly-finch, and helmet-birds (*Turdus pygmaeus*), not to mention doves, snipes, and other more familiar types. Snakes are extremely common—*Crotalus rhomboides*, *Atractaspis irregularis*, *Dendroaspis Jansoni*, *Dargyllia palmorum*, &c.; but they give comparatively little trouble. The curious climbing-fish, which frequents the mangroves, the *Pteroporus* or lung-fish, which lies in the mud in a state of lethargy during the dry season, the strange and poisonous *Tetrodon guttifer*, and the herring-like *Pellona africana*, often caught in great shoals—are the more remarkable of the fishes. Oysters are got in abundance from the lagoons, and the Portuguese catch the huge *Cardium arcticum* or heart-crab for table. Fleas and unfortunately also mosquitoes and sandflies are among the most familiar forms of insect life; the bird spider among the rarer. A kind of ant built very striking pent-house or umbrella-shaped nests rising on the tree trunks one above the other like the roofs of a Chinese pagoda.

Well-built and tall (average height of the men 5½ feet, of the women 5½), strongly dolichocephalous and very thick of skull, never black but of various shades of warm brown with the faintest suggestion of purple, the Balotes (as the natives of the Loango coast call themselves) are on the whole very favorable specimens of the Negro stock to which they belong. Their black curly hair never becomes white with age, and gray only in the case of very old people. Baldness is quite unknown, and many of the men wear beards. Physical deformity is extremely rare. Like the west-coast negroes in general the Balotes have a ghastly and grotesque belief in fetichism and witchcraft; and their gongs or priests employ the *casas* (*nkosses*)

ordel with such recklessness that for every grown-up person who dies a natural death three or four, it is estimated, perish by the judgment of the movable powers. A custom which readily catches the eye of the foreigner is that of setting their marriageable maidens forth to view in a little bower specially erected in front of the parents' dwelling—their skins stained red with a peculiar powder. Near Chunchos there is a curious tribe, the Masimari or Umasimari, known to Europeans as Black Jews on account of their strikingly Semitic features. The coast people proper or Bavilli look down on their more inland neighbours as less civilized, and these in their turn pay the same compliment to those beyond—the Bayombe and Bayaka, who occupy the most mountainous woodland on the borders of Loango, being reckoned as genuine savages.

The people are scattered throughout the country in small villages. Nkondo, probably the largest, contains only 360 to 400 huts, though it is the seat of one of the most influential "princes." There is no town or village of Loango,—the place of that name on Loango Bay being a more group of factories. Barr, Boan, or Boli, was the name of the former capital, Loangui or Loongale (visited in 1873 by Bastian) was the burial-place of the ancient kings; and Labu, which is still neutral in war, is that of the "princes." At one time included in the great Congo kingdom, Loango became independent about the close of the 16th century, and was still of considerable importance in the days of Abbé Prévost (1760), though Kakongo and other districts were practically independent. At present there is no central authority in the country, the petty local chiefs are local chiefs and nothing more; but the members of the blood royal are still honoured with special privileges, a large number of nominal titles remain in use, and a common tradition of greatness gives a sort of cohesion to the political conglomerate.

The slave trade was longer maintained in Loango than anywhere else on the West African seaboard; and since its extirpation palm oil and indiarubber have been the main objects of commerce. Perfect freedom of trade prevails, and there are Dutch, Portuguese, German, French, and English factories on the coast and up the rivers. The Portuguese have made considerable efforts to secure territorial supremacy; but they have hitherto failed, partly owing to direct French opposition, partly to the state of the country.

The following are the principal trading posts:—Bamama at the mouth of the Congo, the central post of the Rotterdam African Trading Company, whose comptoirs are scattered along a vast extent of the west coast, Muanda, with one of the best of the native villages; Vista; Kabinda, the natives of which are known as far south as Mossamedes for their enterprise and skill as hunters, sailors, &c.; Landane, the seat of Dutch, French, and Portuguese factories, and of a French mission from the Gaboon; and Chimocho or Tchimochoho (5° 9' 14" S lat., 12° 8' 46" E. long.), the post occupied by the German Exploring Expedition in 1873-74.

See, besides Merolla and Bates (Pittsburg, vol. ii.), Probst, *Statistik von Loango*, Paris, 1768 (also in Pittsburg); Degener, *Reise nach der westlichen Küste von Afrika*, Weimar, 1861; Bastian, *Die deutsche Expedition an der Loango-Küste*, Jena, 1874-76; and *Die Loango-Expedition*, by Dr. Paul Gieseler (1875), Julius Falkenstein (1876), and Fiedler-Löschke (1869).

LOBELIA, L., the typical genus of the tribe *Lobelieae*, of the order *Campanulaceae*, named after Matthias de Lobel, a native of Lille, botanist and physician to James I. It numbers about two hundred species, natives of nearly all the temperate and warmer regions of the world, excepting central and eastern Europe as well as western Asia. For the sections into which the genus is divided, see *Genera Plantarum*, by Bentham and Hooker, vol. ii. p. 561; and for species, De C. *Prod.*, vii. p. 567. Two species are British, *L. Dortmanna*, L., named after Dortmanna, a Dutch druggist, which occurs in gravelly mountain lakes; and *L. urens*, L., which is only found on heaths, &c., near Axminster (see Baxter's *Brit. Gen.*, No. 79). The genus is distinguished from *Campanula* by the irregular corolla and completely united anthers, and by the excessive acidity of the milky juices. The species earliest described and figured appears to be *L. cardinalis*, L., under the name *Trachelium americanum* var. *cardinalis plantae*, "the rich crimson cardinal's flower"; Parkinson (*Paradiisus*, 1629, p. 366) says, "It groweth neere the river of Canada, where the French plantation in America is seated"; De Candolle records it from New England to Carolina (*Prod.*, vii. 382). This species, as well as several others, are in cultivation as ornamental garden plants, e.g., the dwarf blue *L. Erinus*, L., from the Cape, which, with its varieties, forms a familiar bedding plant. *L. splendens*, Willd., and *L. fulgens*, Willd., growing from 2 to 4 feet high, from Mexico, have scarlet flowers; while *L. amena*, Mich., from North America, as

well as *L. siphilitica*, L., and its hybrids, from Virginia, have blue flowers. The last-named was introduced in 1666, according to Paxton (*Bot. Diet.*, p. 840), but is not mentioned by Parkinson. Certain species of *Lobelia* are used medicinally, the chief being *L. inflata*, L., a native of north-eastern America, called "Indian tobacco," as its effects are very similar to those of tobacco; for its localities, &c., see Pickering, *Chron. Hist. of Pl.*, p. 1015. It is expectorant and diaphoretic in small doses, but in full medicinal doses is nauseating and emetic. It is used for spasmodic asthma, and as an adjunct to diuretics. See Bentley and Trimen's *Med. Pl.*, No. 162; *Pharmacographia*, p. 357; and Pereira's *Mat. Med.*, vol. ii. pt. ii. p. 8. For active principles, see *Pharm. Journ.*, vol. x. pp. 270, 456. Another medicinal species is *L. siphilitica*, L., the blue cardinal, of which the root is used by the North American Indians for the purpose implied in the specific name. The value, however, is said to have no foundation in fact (Pearson, *Obs. on var. Art. of Mat. Med.*, p. 70), but see *Amer. Dispens.*, p. 494. A third species is *L. decurvens*, Cav., from near Arequipa in Peru, where the Indians use it as an emetic (*Pharm. Journ.* [1], vol. xiii. p. 14).

LOBO, LEBONIMO (1698-1678), a Jesuit missionary, was born in Lisbon in 1698, and entered the Order of Jesus at the age of sixteen. In 1621 he was ordered to repair as a missionary to India, and in 1622 he arrived at Goa. With the intention of proceeding to Abyssinia as a missionary, he left India in 1624, but after disembarking on the coast of Mombasa, and attempting to reach his destination by land, through the Galla country, was forced to return. Repeating the attempt in the ensuing year, in concert with Mendes, the newly-appointed patriarch of Ethiopia, and eight missionaries, Lobo landed on the coast of the Red Sea, and settled down in Abyssinia as superintendent of the missions in the state of Tigre, travelling about a good deal over the country, and thus obtaining much valuable information on its geography and people. He remained at his post for some years, until death deprived the Catholics of their protector, the emperor Segued. Forced by persecution to leave the kingdom, in 1634 Lobo left, along with his companions, into the hands of the Turks at Massowah, and was sent by them to India to procure a ransom for his imprisoned fellow-missionaries. This object he gained, and at the same time he endeavoured, though without avail, to persuade the Portuguese viceroy to send an armament against Abyssinia. Intent upon accomplishing this cherished project, he embarked for Portugal, and after he had been shipwrecked on the coast of Natal, and captured by pirates, arrived at Lisbon. Neither at this city, however, nor at Madrid and Rome, was any countenance given to Lobo's plan for Christianizing Abyssinia by the aid of arms. He accordingly returned to India in 1640, and was elected rector, and afterwards provincial, of the Jesuits at Goa. After some years he returned to his native city, and died there January 29, 1678.

Lobo wrote an account of his travels in Portuguese, which appears never to have been printed, but is deposited in the monastery of St Roque, Lisbon. Belthier Tellez made large use of the information therein in his *História Geral do Etyopia Alia* (Coimbra, 1660), which is often erroneously attributed to Lobo (see Machado's *Bibliotheca Lusitana*). Lobo's own narrative was translated from a MS. copy into French, under the title of *Voyage Historique de Anseville*, by the Abbé Legrand, Paris, 1728. In 1669 a translation by Sir Peter Wythe of several passages from a MS. account of Lobo's travels was published by the Royal Society, and this was translated into Thénard's *Relation des Voyages* in 1678. An English abridgment of Legrand's edition by Dr Johnson was published in 1786, and reprinted in 1788. In a *Mémoire posthume en réhabilitation des Pères Paez et Jerome Lobo*, Dr C. T. Debs maintains the accuracy of Lobo's statements as to the source of the Arab branch of the Nile against Bruce.

LOBSTER. See CRUSTACEA, and FISHES, vol. ix. p. 265.

LOCK—not being a canal lock—means the fastening of a door, or box, or drawer, which requires a key, or else some secret contrivance or manipulation, to open it. It is generally fixed to the door, but it may also be loose, and then it is called a padlock, which is internally like other locks, but externally has a half link or bow turning on a hinge at one end, while the other, after being put through a chain or staple on the door, enters the lock and is fastened by the bolt therein. The bolt may be moved by the key, or may close by a spring, but require a key to open it, as in the case of handcuffs, which are a pair of padlocks of this kind united by a short chain. A common door lock also comprises a spring latch which opens by a handle, and sometimes a small bolt held by friction either shut or open, which is moved by a smaller handle inside the room only, but neither of these is the lock proper, any more than a hook or a button, or a common lifting latch. Therefore, omitting them, a lock is as defined above.

The earliest lock of which the construction is known is the Egyptian, which was used four thousand years ago. In fig. 1, *aa* is the body of the lock, *bb* the bolt, and *cc* the key.

The three pins *p, p, p* drop into three holes in the bolt when it is pushed in, and so hold it fast, and they are raised again by putting in the key through the large hole in the bolt and raising it a little, so that the pins in the key push the locking pins up out of the way of the bolt.

The security of this is very small, as it is easy enough to find the places of the pins by pushing in a bit of wood covered with clay or tallow, on which the holes will mark themselves, and the depth can easily be got by trial.

Mr Chubb, the well-known lock-maker, used to show a wooden Chinese lock very superior to the Egyptian, and, in fact, founded on exactly the same principle as the Bramah lock, which long enjoyed the reputation of being the most secure lock ever invented, for it has sliders or tumblers of different lengths, and cannot be opened unless they are all raised to the proper heights, and no higher.

Until about a century ago no lock so good as this was known in England. The locks then in use (fig. 2) were nothing better than a mere bolt, held in its place, either shut or open, by a spring *b*, which pressed it down, and so held it at either one end or the other of the convex notch *aa*, and the only impediment to opening it was the wards which the key had to pass before it could turn in the keyhole. But it was always

Fig. 3

Fig. 4

possible to find the shape of the wards by merely putting in a blank key covered with wax, and pressing it against them, and when this had been done, it was by no means necessary to cut out the key into the complicated form of

the wards (such as fig. 3), because no part of that key does any work except the edge *bc* farthest from the pipe *a*, and so a key of the form fig. 4 will do just as well, and a small collection of skeleton keys, as they are called, of a few different patterns, were all the stock in trade that a lock-picker required.

The common single-tumbler lock (fig. 5) was rather better than this, as it requires two operations instead of one to open it. The tumbler *at* turns on a pivot at *t*, and has a square pin at *a*, which drops into a notch in the bolt *bb*, when it is either quite open or quite shut, and the tumbler must be lifted by the key before the bolt can be moved again. But this also is very easy, unless the lock is so made that the tumbler will go into another notch in the bolt if it is lifted too high, as in the lock we shall now describe, which was the foundation of all the modern improvements in lock-making.

Barron's Lock.—This was the first lock with several tumblers. It was patented in 1778. Fig. 6 is a front view, and fig. 7 a horizontal section. First consider it with reference to one tumbler *at* only. Unless the square pin *a* is lifted by the key to the proper height, and no higher, the bolt cannot move, and that alone adds very considerably to the difficulty of picking, except by a method not discovered for many years after.

But Barron added another tumbler, and unless both were raised at once to the proper height, and no higher, the lock could not be opened. The face, or working edge, of the key of a many-tumbled lock assumes this form (fig. 8), the steps corresponding to the different heights to which the tumblers have to be raised, and one of them acting on the bolt, and they may have a much wider range of difference than in this figure.

The key here drawn is also one with the wards of such a shape that no skeleton except itself can pass them. The form, however, can be got in the usual way by a wax impression; and as it weakens the key very much, and is expensive to cut, it is not often used.

Bramah's Lock.—The next lock of any importance was the celebrated one patented ten years after Barron's, by Joseph Bramah (see BRAMAH). In figs. 9 and 10 *aaaa* is the outer barrel of the lock, which is screwed to, or cast with, the plate, *cccc* is a cylinder, or inner barrel, turning within the other. It is shown sepa-

Fig. 5

Fig. 6

Fig. 7

Fig. 8

Fig. 9

rately at fig 11, and fig 12 is a cross section of it, the black ring being the keyhole, and the light spot in the

Fig 10

middle the drill-pin, which goes into the key. The short pin d in figs. 9, 10, 11 is set in the end of the cylinder,

Fig 11

Fig 12

near its edge; and, when the cylinder turns round, that pin shoots or draws the bolt, by acting in a slit of the form shown in fig 13. The security of the lock depends upon a number of sliders, a, s , of which the shape is shown in fig 14, and the cross section in fig 12. They are made of plates of steel doubled, and sprung open a little, so as to make them move with a little friction in the slits of the cylinder or revolving barrel in which they lie, and are pressed up against the cap of the lock by a spiral spring. They are shown so pressed up in fig 9, and pressed down by the key in fig 10. There is a deep groove cut round the barrel, and in each of the sliders there is a deep notch which can be pushed down to that place in the barrel by a key slit to the proper depth; and it is evident that when all the sliders are pushed down to that position the barrel will present the appearance of having no sliders on it. A steel plate (fig 15), made in two pieces in order to get it on, embraces the barrel at the place where the groove is, having notches in it corresponding to the sliders, and is fixed to the body of the lock by two screws marked d, d in figs. 9, 10, and 15. When the sliders are pushed up by the spring they fill the notches in the plate, and prevent the barrel from turning, but when they are pushed down by the key the notches in the sliders all lie in the plane of the plate, and so the barrel can turn with the key, and the pin d in the end of it drives the bolt as before described. The key has a bit, k , sticking out from the pipe, the use of which is to fix the depth to which it is to be pushed in, and then, as the bit slips under the cup of the lock, it keeps the key at the same depth while it is being turned.

This was the construction of the lock for a good many years, and Bramah pronounced it in that state "not to be within the range of art to produce a key, or other instrument, by which a lock on this principle can be opened." It was found, however, long before the defeat

of the improved challenge Bramah lock by Mr Hobbs in 1851, that the inventor had made the common mistake of pronouncing that to be impossible which he only did not see how to do himself. As it has been generally supposed that what is called the tentative method of lock-picking was unknown in England before it came over from America in the year of the Exhibition of 1851, we must remind our readers that it was described in the 7th edition of this work fifty years ago, though the lock-picking fraternity were not of sufficiently literary habits to make themselves acquainted with it. Mr Hobbs, it is true, carried the process further than had been supposed possible before, but all the Barron and Chubb and other many-tumblered locks, which were supposed impregnable, might long ago have been opened by anybody who had paid attention to the method by which the Bramah locks were known to have been picked some seventy years ago, before the introduction of the false notches designed in 1817 by Mr Russell, then one of Mr Bramah's workmen. If you apply backward pressure to the bolt of a tumbler lock when locked, or twisting pressure to the barrel of a Bramah lock, first pressing down the spiral spring, there will be a greater pressure felt against some of the tumblers or sliders than against others, in consequence of inevitable inequalities of workmanship; and if you keep the pressure up, and gently move any of the tumblers or sliders on which the pressure is felt, you will at last get it to some point where it feels loose. That may or may not be the exact place to which the key ought to lift it, but as soon as you feel it loose leave it alone, it will not fall again, as the friction is sufficient to prevent it, and, if necessary, you may fix it there by a proper instrument, or measure the depth and keep the measure till you begin again. Then try another tumbler which feels tight, and raise it till it also feels loose. And if you go on in that way, always leaving the loose tumblers alone, and raising the one which feels tight, they will at last all be got into the position of complete freedom, *i. e.*, to the place where the stump of the bolt can pass them. The operation is just the same in principle in the Bramah lock and in tumbler locks; only, as all the sliders are acted on by one spring in the Bramah as now made, you need only just push down that spring, and hold it there, and then the sliders may be moved freely either way by means of a hook or a small pair of self acting forceps to pull them up if they accidentally get pushed too far. At first each slider had a separate spring.

But if the sliders have some false notches in them not so deep as the true ones (see fig 14), and the corners of

Fig 11

Fig 15

the notches in the plate d, d are cut out a little (as in fig 15), then you might by trial get all the sliders into such a position that the barrel could turn a very little, but no more; and when it is turned that little, you cannot push the sliders any further, and so (as was long supposed) the tentative process is defeated, and undoubtedly it is made much more troublesome, but it only requires more time and patience. You can still feel that the pressure is greater against some one or more of the tumblers or sliders than against others, and, whatever that is the case,

you know that it must be at a false notch, and not the true one, for a true one gives no pressure at all. Proceeding in this way, Mr Hobbs opened the challenge lock with eighteen sliders, or guards, which had hung in Messrs Bramah's window for many years, in nineteen hours, and would have done it sooner, but that one of his instruments broke in the lock. He afterwards repeated the operation three times within the hour, in the presence of the arbitrators; and a more recent one with eight sliders he opened in four minutes, by means of an instrument which is equivalent to a Bramah key with adjustable slits, which are set to the sliders as the operation of feeling them and getting their depths goes on. It is, moreover, to be remembered that thieves do not always confine themselves to the conditions of a challenge, in which force and injury to the lock are of course prohibited; and, if a lock can be easily opened by tearing out its entrails, it is of very little use to say that it would have defied all the arts of polite lock-picking. In this respect the Bramah lock is singularly deficient; for if the exposed cap or nozzle of the keyhole is cut off, as it easily may be, or if the hole is widened out by a centre-bit, the sliders can be all pulled out, and there is an end of the lock.

Inside and Outside Locks.—Locks for drawers, closets, iron chests, and the like are only required to lock on one side, and their keys are therefore generally made with a pipe, which slips on to a pin in the lock called the drill-pin, and turns on it. Doors which have to be locked sometimes on one side and sometimes on the other cannot have their keys made in this way, the key is solid, and its plug or stem, being thicker than the flat part or web, acts as an axis fitting into the upper part of the keyhole, though that hole does not completely enclose it. All keys for these inside and outside locks must be symmetrical, or alike on each side of a line through their middle, in order to fit the lock either way, which limits the variety of the tumblers in the case of many-tumbled locks. A Bramah lock, to open on both sides, must be made double, with one set of sliders to push in from one side of the door, and the other set from the other side, and, consequently, they are very seldom used for this purpose. It may be convenient to observe that when we use the term Bramah lock we mean a lock of that construction, for, the patent having long ago expired, such locks may be made by anybody, only Bramah's name must not be used. Messrs Morian's locks are the same as Bramah's, except that they make the number of sliders odd, while Messrs Bramah make it even.

Letter Locks.—At one time it used to be supposed that locks which could only be opened by setting a number of rings or disks to a particular combination of letters could not possibly be opened by anybody who was not in possession of the secret; and hence they were also called puzzle-locks. At first they were made with a fixed combination, which could not be changed. Afterwards the rings were made double, the inner one having the notch in it which the bolt had to pass, and the outer one capable of being fitted on to the inner in any position, by unscrewing some part of the lock, so that you might set them to any combination desired. This was the first instance of a changeable lock, of which we shall have more to say further on. But it was afterwards found that these puzzle locks have just the same vulnerable point as all our locks had until lately, viz., that the pressure of the bolt can be felt on some of the rings more than on the others, and Mr Hobbs says emphatically, in the *Elementary Treatise on Locks*, "wherever that is the case, that lock can be picked." Apart from this defect, these locks have very much gone out of use on account of their being troublesome to handle, and perhaps also from the risk of forgetting the combination to which the lock was set last, if it has been left for some

time, and therefore we do not think it necessary to go farther into the details of their construction.

Chubb's Locks.—Of the multitude of locks which have been made on the many-tumbler principle invented by Barron, none enjoyed so much celebrity before Hobbs's as Chubb's. This was partly due to superior workmanship and use of more tumblers than usual, and perhaps still more to the inventor having had the good fortune to hit upon the name "detector" for a certain part of the machinery, which, besides adding to the security against any mode of picking then known, also captivated the public with the idea of discovering if anybody had been tampering with the lock, though the operator might depart in ignorance that he had left any trace of his attempt behind him. It is remarkable that the detector was not even then a new invention, for a lock exactly the same in principle, but slightly different in arrangement, had been previously made by a Mr Ruxton, and is described in Price's treatise on *Locks and Keys*, &c., 1856. In the same way false notches were used in Sturt's tumbler lock above thirty years before they were reinvented, by Chubb and others, with the idea of defeating the tentative method of picking by them. In all lever or tumbler locks there is a square pin B, called the stump, rivetted to the bolt, which has to clear the passage in the tumblers called the gating. The original form of Chubb's detector is shown in fig. 16 by

Fig 16

the lever DT, which turns on a pin in the middle, and is acted upon at its end T by a spring S, which will evidently allow some play to the lever on either side of the corner X, but the moment it is pushed past that point the spring will carry it further in the same direction, like what is called in clock-work a jumper. In its proper position that end always remains above the tuning-point; but, if any one of the tumblers is raised too high, the other end D of the detector, which reaches over all the tumblers, is lifted so far that the end T is sent down below the corner, and the tooth T then falls into a notch in the bolt, and so prevents it from being drawn back, even though all the tumblers are raised properly by the right key, which at once reveals that somebody has been trying to pick the lock. The way to open it then is to turn the key the other way, as if to overlock the bolt; you observe a short piece of gating near the end of the tumblers, to allow the bolt to advance just far enough to push the tooth of the detector up again by means of its inclination there, and then the lock can be opened as usual. In some more recent locks the tumbler is made in another form. The back tumbler, or the one which has to be raised highest, has a pin d reaching over all the others, and if any of them are overlifted that back tumbler is also, and then a square corner k in it gets past the end of the detector spring k', and is held up. It is set right by overlocking the bolt as before, the bolt itself raising the end k of the spring, and

letting the tumbler fall. This form of detector is, however, inferior to the other, as it informs the picker what he has done, by the back tumbler itself being held up, which he can feel directly.

But since Mr Hobbs's mode of picking locks became known all these detectors have become useless. Some persons have even gone so far as to say that the detector may be made a guide to picking. Whether this be so or not, the detector does not act unless some of the tumblers are raised too high, which they never are by a skillful operator on this plan, nor does it act (even if thrown by accident) against picking backwards, or feeling the way to shoot the bolt a little further, as if to free the detector, and in this way the measure of the key can be taken without any hindrance from the detector. Before 1851 tumbler locks were seldom made with false notches, except Strutt's, in which the tumblers were in the form of quadrants, with a very large angular motion, and a number of short or false notches and one deep one. But after that year Chubb and other makers of tumbler locks adopted false notches, together with revolving curtains, which cover the straight part of the keyhole as soon as the key is turned, and barrels going down from the back of the curtain to prevent a false key or pick from turning without turning the curtain, other obstacles were added, of which the object is in all cases to prevent the maintaining of pressure of the stump upon the tumblers at the same time that the tumblers themselves are moved, or, as Mr Hobbs called it, tickled, by some other instrument. These provisions undoubtedly make the locks more difficult to pick, but it is by no means safe to assume that a lock will never be picked, merely because it would take a first-rate hand a long time to do it or gradually make his key.

Hobbs's Lock.—The invention which most directly meets the defect of all previous locks is Mr Hobbs's "movable stump," which is not rivetted into the bolt as usual, but is set on the end *b* of a bent lever *abc* (fig. 17) which lies in a hollow of the bolt *A* behind it, turning on a pivot in the bolt itself, and kept steady by a small friction-spring *e*. The stump comes through a hole in the bolt large enough to let it have a little play, and the long end *a* of the lever stands just above the edge of a square pin *d*, which is fixed in the back plate of the lock.

Fig. 17.

When the lock is locked, if you push the bolt back, you produce no sensible pressure on the tumblers, but only just enough to turn this protector lever, as Mr Hobbs calls it, on its pivot *c*, and so bring down its end *a* in front of the square pin, and then the bolt can no more be pushed back than when held by Chubb's detector. The protector is set free again by merely pushing the bolt forward with the key, without reference to the tumblers. It was found, however, that in this state the protector could be prevented from acting by a method used by the inventor himself for another purpose, viz, pushing a piece of watch-spring through the keyhole, and up behind the bolt, so as to reach the protector at *a*, and keep it up while you push the bolt back, or, again, by pushing up the watch-spring between any two of the tumblers, and holding the end *b* of the protector with it, so as to press the stump against the tumblers. Both these devices, however, are prevented now by letting in a feather FF in a groove between the bolt and the back of the lock, which no watch-spring can pass, and also bringing a piece of the feather forward through the front gating of the tumblers just under the stump. In this form the lock is safe against any mode of picking at present known, unless the keyhole happens to be large enough to admit the inspecting method, which is this. A person in-

tending to pick the lock goes beforehand and smokes the bollocks, or lower edges of the tumblers, through the keyhole. When the key comes, it wipes off the black on each tumbler, according to the length of the bit which raises it, and then, when the picker returns, he throws a strong light into the keyhole, and, by means of a narrow reflector put into it, reads off, as it were, the length of bit required to raise each tumbler to the proper height. This operation may sound impossible, but it is an established method of lock-picking in America. It requires a largish keyhole, however, and it may be prevented by any kind of revolving cylinder which will conceal the view of the tumblers while the keyhole is open. The inspecting method might also be frustrated by making the acting part of the bollocks of all the tumblers no longer than would be reached by the shortest bit in the key. In that case, the long bits would not begin to act at their points, but on their sides, and would leave no measure of their length upon the tumblers.

A multitude of other many-tumbler locks acted on by springs, and with various kinds of detectors and revolving curtains, all more or less upon the same principles, may be seen described in Price's book above-mentioned, but we are not aware that any of them have ever come into general use, or are superior to Chubb's or equal to Hobbs's protector locks. There is another group of locks which involve fanciful and thick ugly keys, and for that or other reasons have not got much beyond patents and exhibitions. "Revolving curtains" have been proved to be less serious impediments to picking than they would seem, inasmuch as they must leave room for an instrument no thicker than the key itself to turn. The only kind of curtain that is not open to this objection must be one that absolutely prevents any touching of the bolt while any instrument at all is within the lock, and projects at all outside. Mr Hobbs accomplished that by the odd-looking contrivance of a key consisting only of its web, or flat or acting part, which is pushed into the lock, and then carried round by a fixed handle in another place, which closes the keyhole until it has come round again and delivered the key-web ready to be taken out by a proper hook. But this was too troublesome for common use. The same object is effected in another way by Sir E. Beckett's lock, which we shall presently describe.

Tucker's Locks.—There have been several locks on the disk principle invented in succession by Mr Tucker of Fleet Street, London, the first two of which had revolving disks, and in the last and more simple one, patented in 1855, though the disks no longer revolve, they slide between fixed plates without springs, and do not turn on a pin like common tumblers, and will stand in differently any where. It will be sufficient to describe the last of these inventions, as Mr Tucker himself states it to possess all the elements of security of the former ones, with the advantages of being much cheaper, because more simple in construction. In fig. 18 TT is one of the sliders, which are separated by thin fixed plates, and slide upon the guide-pins at TT, and have also friction-springs X pressing on them to keep

Fig. 18

sem steady S is the bolt stump, which can only enter I, the gating of the tumblers, when they are pushed the proper distance towards the left, which the key will do as soon as it turns towards the left, in the usual way of unlocking. But something else still prevents the bolt from sliding, and that is the flat curtain C, which turns with the key, and has also a barrel B, as in several of the others we have spoken of. This curtain prevents the stump from being pressed against the tumblers, being just big enough to keep it from touching them until it has turned nearly three quarters round, when the pin S, which stands up on the stump, can enter the opening D in the curtain shown by a dotted line in the drawing, to prevent confusion. But by the time the curtain has got so far round, any instrument in the keyhole would be prevented by the barrel from reaching the tumblers so as to push them back and feel the presence of the stump, at least so the inventor asserts, and we do not venture to contradict him, but it must be remembered that no revolving curtain and barrel have yet been able to prevent the instruments of the American lock-pickers from reaching and moving the tumblers at the same time that the barrel is being pressed the other way in order to keep up pressure on the bolt.

We have not yet explained how the bolt in this lock is drawn back when the curtain has got into the proper position for it. It is not done by the last bit in the key acting directly on the bolt as usual, but by a bit P fixed on the curtain itself, which acts upon the notch B in the bolt, as the key usually does. And thus same bit P performs another function in locking, viz., shooting all the tumblers into the position here shown by striking against a pin which is set in the bottom one, and comes up to the curtain, and so carries all the others with it by means of the square notch which is cut in all of them, except the one which has the pin in it. It must be observed that the curtain does not lie close upon the tumblers, but there is the thickness of the bolt, or of the bit P, between them. A spring locks into the curtain and prevents it from being retracted, except when this spring is pressed down by putting the key into the keyhole. One object of making the curtain, and not the key, to lock and unlock the bolt is that you guard against the risk of what is called short-locking, i.e., ending the bolt in any common tumbler-lock not quite far enough for the tumblers to drop. There are means by which a person intending afterwards to pick a lock might cause it to lock short, if he had previous access to it, or possession of the key, at least as locks are generally made, and then, of course, he has only to pull the bolt back, the tumblers having never fallen. Moreover, this arrangement of Tucker's lock allows it to be locked by any key that will turn in the keyhole, though it cannot be unlocked by any but the true key, or one which will move all the tumblers to the right place for the stump to enter them. If Tucker has also applied the curtain in his padlocks in such a way that the shackle has a tail reaching inwards and resting against the curtain at all times, except when it is in the proper position for opening, i.e., when this tail is opposite to a segment cut out of the curtain corresponding to the opening D in the lock just now described, but much larger. The object of this is to obtain greater strength than usual to resist all attempts to force the shackle open. The cheapness of these locks is due to the circumstance that all the principal parts can be stamped out of sheet brass, the curtain alone being cast with the barrel and bit on it, and its face turned, which is a cheaper operation than filing. In this respect it approaches to Mr Hobbs's style of lock-making; only he has carried the stamping and machine-finishing system much further; indeed, it is hardly exaggerating to say that he has abolished the use of the file, and left nothing to hand labour except the mere fitting

of the pieces together, and putting the tumblers in the right position to have the gating cut according to the key.

Nettlefold's Bolt.—We have already alluded to padlocks, and we shall do so no farther, because they are generally of exactly the same internal construction as other locks of the same maker. And, for the same reason, it is unnecessary to describe the various modifications of the fastening part of locks to adapt them to peculiar uses or positions, but there is one which does seem to be worth a short notice, viz., an invention of Mr Nettlefold, patented in 1839, for making the bolt hook into the striking plate, against which it locks. Fig 19 will explain the nature of the contrivance at once. We have inserted no tumblers, because it may be used with one kind of lock as well as another. It is convenient for writing-desks, sliding cupboards, and even for drawers, which can often be prized open by merely putting in a screwdriver above the lock, and forcing up the piece over

Fig 19

it just enough to let the bolt, which is generally short, pass. There are other ways of doing the same thing, such as making the bolt itself hooked, and giving it two motions, first vertical, to shoot it out, and then horizontal, to hook it into the striking plate, and some Bramah locks are made with a kind of annular bolt, which forms a rim to the cylinder, with a segment cut off in one place to let the striking plate come down, which is then taken hold of by the other part of the ring as it revolves. Bramah locks of portfolios, and articles of that kind, are usually made in this way, which is very cheap and simple.

Master-Keys.—It is often convenient to have a set of locks so arranged that the key of one will open none of the others, and yet the owner of the whole may have one master-key that will open them all. In the old locks with fixed wards this was done by making the wards of a slightly different form, and yet such that one skeleton key will pass them all, just as the skeleton-key in fig. 4 will serve for the warded key of fig. 3, and a multitude of others. In locks with sliders or tumblers, the way is to make one tumbler in each lock with a wider gating, so as not to require lifting so high as it does in the other locks of the set; then the key of that lock will raise that tumbler in that lock high enough to clear the stump, and yet the master-key, which has a longer bit in that place, will not raise it too high, because the gating is wide enough for both; but the special key of that lock will not open any other of the set which has not the same tumbler widened in the gating. Mr Chubb, many years ago, made a set of locks for the Westminster Bridewell, with keys for the different grades of officers. The owner of the head key can stop out any of the under keys, and any attempt is made to pick any lock, and the detector is thrown, it cannot be released by any of the subordinate keys, though they can open the lock in its normal state, and consequently the governor must be acquainted with it. There are a variety of other forms of many-tumbler locks, but none of them involve any novelty in principle, and they are all capable of being dealt with in the same way, and therefore we shall at once pass on to another class of locks, viz., those which shut of themselves, and are called—

Spring or Latch Locks.—These locks we chiefly notice because they require a particular provision to make them in the smallest degree secure, and are, nevertheless, often left without it, by way of saving a shilling or two in their price, and multitudes of street-door robberies are committed in consequence. The former of these two names is

generally used for a lock which shuts of itself on a box or drawer; or articles of that kind, and the latter for street or room-door locks which shut of themselves, and open with a handle on the inside, but only with a key on the outside. In the simplest and cheapest form of these locks there is no pretence of any security except a few fixed wards, which the key has to pass; and, as before explained, that is no security at all against anybody with the smallest dexterity, and with a serious intention of opening the lock. Next to them, or rather below them, pretending to be what they are not, come the locks which lock a certain distance themselves by means of a spring, but can be locked further by the key, and have tumblers, but no fixed wards (which a good tumbler-lock does not require). But though this kind of lock cannot be opened when it is thus double locked, except by the key, or some efficient mode of picking, yet when they are only self-locked the tumblers are of no more use than if they did not exist, and the lock can be opened by any bit of bent wire that will go into the keyhole. It should be remarked, however, that the Bramah lock is just as secure as usual when used for a spring or latch lock, because the key cannot turn at all without pushing in the sliders properly. But in this, as in all latch-locks, it is very unsafe to have a handle which pulls back, as it can easily be reached by a wire put through a hole in the door; the handle should always be made to turn, like a common room-door handle.

There are two ways in which spring-locks with tumblers are made as safe as the same lock with an ordinary bolt. One is to make a click or catch fall into the bolt when it is drawn back, and not to make the tumblers to fall when the bolt is drawn back, in the shutting of the door this catch is pushed back by some knob projecting for the purpose, and then the tumblers fall and hold it fast. Prison locks are made in that way. But this will not do for a latch-lock which is intended to open by a handle on one side of the door. For that purpose the proper plan is that which is now adopted in all good latch and spring locks, not to let the key act directly on the bolt, which has no stump, but on the false bolt which lies on the top of the real one, and has the stump fixed in it. When the real bolt is shut by the spring it carries the false one with it, and that is then locked by the tumblers. But the real bolt can be pushed back by the door shutting, or pulled back by the handle, without moving the false bolt, though it cannot be reached through the keyhole. In buying a lock, the test of this is to see whether the stump moves as you push or pull the bolt back. If it does the lock is good for nothing, unless it is on some other peculiar construction.

Latches and Latch Locks.—The latter of these, so called by Mr. Chubb, is substantially on the principle just now described, and so is Hobbs's and Hart's latch lock, which also has the protector stump, and therefore is as unpickable as their other locks, provided neither the handle nor the bolt can be got at. Chubb's latch (not his latch-lock) consists only of four tumblers, which come out and form the bolt, and fit between a sort of mouth in the striking-plate on the door post, and have all to be lifted to the same height by the key; but that can easily be picked by the tentative method, though it might delay a common street thief for an inconvenient time.

Spring Curtain.—All latch locks for street doors are liable to stick fast through dirt getting between the tumblers, especially in a smoky town. They will keep clean much longer if the keyhole is protected by Sir E. Beckett's self-acting spring curtain, which can be added to any lock which is worth it. It consists only of a small thin steel plate, sliding on the key-pin, and another pin just below the keyhole to guide it, with a slight spring

behind, for which there is room in any latch lock with a sliding locking plate over the bolt. They are not patented, and the cost is quite insignificant, and it is odd they are not more commonly insisted on by purchasers.

Safe Locks with Small Keys.—In all the locks we have yet mentioned the bolt is acted on by the key, even though the key may not touch it, the key must therefore be strong enough to move the bolt besides lifting the tumblers, or whatever is substituted for them, and this makes the key for a large lock too large and heavy to be conveniently carried in the pocket, and a bunch of such keys impossible. To get over this difficulty, most of the makers of iron safes have adopted the plan (we do not know by whom invented) of shooting a large bolt, or a number of bolts, by means of a handle, and then a small lock with a small key locks into one of them, and thus fastens them all. The security then depends upon the impregnability of the small lock against fraudulent picking or forcible eversion. There are certain thieves' instruments by which a force sufficient to tear open the inside of a lock can be inserted through a keyhole of the common size. This, however, is now defeated by cutting out a piece of the back plate, and then sawing it on again with only a few small screws, and so that alone gives way under any bursting pressure, whether from the instrument called the jack-in-the-box, or from gunpowder, which is another of the thieves' methods for cutting the knot which they cannot untie. If the small lock, therefore, cannot be picked, or forced, this mode of locking the bolts of a large door is quite safe, and you have the advantage of a very powerful lock with nothing to carry in your pocket larger than a small desk key.

Sir E. Beckett's Lock.—A lock was invented by Sir Edmund Beckett (formerly Demson) in 1852, but not patented, which combines the advantages of large and strong works with a keyhole so narrow that no instrument strong enough to injure the lock could be got in, nor a reflector to observe the bellies of the tumblers, and the bolt is not only shot by turning the handle, but locked besides, without using any key at all. This lock enjoys the distinction of being the only one of English invention which was pronounced secure against any known method of picking, by Messrs Hobbs and Tomlinson, in the treatise before referred to.

In fig. 20 are shown the tumblers T, turning on a pin at or near the middle of their length, so as to be really

Fig. 20.

balanced, though in small locks this is unnecessary. Between every two adjacent tumblers, and between the bolt and the tumbler next to it, there is a thin steel plate, which occupies the position shown by the dotted lines PP. These plates have one edge lying against the upper side of the lock, so that they cannot turn at all on the tumbler-pin, which goes through them quite loosely. One or two of the plates should be bent a little to make them act as friction springs on the tumblers when the cap of the lock

is on, so that they will stand indifferently in any position. In the figure they are drawn all pressed down, so as to prevent the stump S from entering the gating, and this has been done by the long tail Y of the handle, which, it is easy to see, will raise the left end of the tumblers, and depress the right, after the fan-tail piece X of the handle has shut the bolt. After the tumblers have been raised to the proper height by turning the key half round (where it may be stopped by the plates P, P), the stump can enter the gating, and the bolt can be drawn back by the handle, the tail Y then doing nothing. So far as we have yet gone, the lock would possess no greater security than any other many-tumbled lock, but there is a steel curtain CC, which does not revolve as usual, but slides on two pins set in the back of the lock, and is pressed up against the front plate by two spiral springs, so as to close the keyhole completely, except when it is pressed in. From the back of the curtain there goes a kind of square plug (shown in section at fig. 21), which can be pushed through

Fig. 21

a hole in the back plate, and has a notch in it just in the plane of the bolt, and the bolt itself has a corner there, in this way, when the curtain is up, the bolt can be drawn back through the notch in the curtain plug, but when the plug is pushed in, ever so little the bolt cannot be drawn back, because its corner cannot pass the curtain plug, and in this position the stump cannot be made to touch the tumblers, except one of them, which is made a little longer than the rest (as shown at T in fig. 20), in order to keep the bolt steady. It is evident then that as soon as the curtain is pushed in, to admit any instrument whatever, the bolt is held fast, and it becomes impossible to put any pressure of the stump upon the tumblers, in other words, the tentative mode of picking is impossible. In small locks the curtain has no plug, but merely works against the edge of a second stump of the bolt, which can only pass when the curtain is up, and it slides on the drill-pin and another pin below it.

The security of the lock is farther increased by the addition (DEG) of what may be called a detector, as it does detect if the bolt has not been shot far enough by the person who locked it, and, what is of more consequence, prevents it from being opened in that state. It turns on a hinge or pin at G, and is held up or down by a jumper-spring at E, as in Chubb's first detector. In fig. 20 it is shown as held down, or out of the way of the bolt, but, as the handle turns back again and draws back the bolt, the pin below X raises the detector a little, and then the spring is ready to throw its tooth into the notch in the bolt as soon as it is shot only about half-way. In that state the bolt cannot be drawn back without turning the handle far enough for the fan-tail X to send the detector down again below the corner of the spring, and by doing that you will also have locked all the tumblers, and so made the lock fast until the key comes to open it. And it is to be observed that the curtain cannot be pushed in until the bolt is fully shot, so that no exploration of the lock can take place while it is open, or even partially open. By adding a spring catch under the curtain, to be freed by one of the tumblers when it is fully locked, it may be arranged, if required, that the curtain could not be pushed in, not only until the bolt is shot, but until the tumblers are locked also.

The following, therefore, are the advantages of this lock. 1 A very large lock, with all its parts strong, only requires a very small key, not weighing above a quarter of an ounce. 2 No key is required to lock it, and you cannot leave the key in the lock (a fruitful source of mischief), and yet it is free from the inconvenience of spring-locks, which sometimes shut themselves when not intended,

and moreover, when large, require large and strong keys to open them. 3 It cannot get out of order from the usual causes of the tumblers sticking together, or tumbler-springs breaking, because there are none, and the tumblers do not touch each other, but the friction-plates between them. 4 The keyhole being always quite closed by the curtain, except while the key is in, the lock is protected from dirt and from the effects of a damp or smoky atmosphere, which injures other locks. 5 The smallness of the keyhole prevents the insertion of any instrument strong enough to force the lock, and also prevents inspection. 6 It is sanctioned by the highest authority to be secure against any known mode of picking. 7 It requires no delivery of construction of high finish in any of the parts, and the moving parts are few—in fact, the whole of them together are fewer than the number of springs alone in the great American lock of Day & Newell. 8 It is free from the innumerable of a patent, the inventor being one of those who agree with the opinion of the jury on philosophical instruments in the exhibition of 1851, and with many of the first engineers and most scientific men, that "patents are a great obstruction to the progress of science," and waste, on the whole, more money than they gain for real inventors.

Changeable Key Locks

Any lock with many tumblers may be changed by taking it off and transposing any two or more of the tumblers, but it will then want a different key, and the process is too troublesome to be resorted to except when there is reason to apprehend that the original key has fallen into bad hands, or had a copy taken of it. A lock which can be locked by a great number of keys, but can only be opened by the one which locked it last, is evidently an immense addition to security. Those keys may either be all distinct, or there may be a great number of different bolts, or stopped parts, fitting to a common handle, or each bit or step may be separate, and all screwed together into the key frame as shown in fig. 22.

Fig. 22

In a lock with a tumbler, each movable to six distinct heights, if you have only a loose bits of the six different heights you may compose $1 \times 2 \times 3 \times 4 \times 5 \times 6$ keys, which for nine tumblers = 362,880. But if you also have six bits for each place in the web, the possible number of different keys is very much greater, viz. 6^6 ; for every possible length of bit in each place may be used with every possible length in every other place. If so is 7 and 8, as they are in the locks we are going to describe next, each lock may have very nearly sixty million different keys, or key-webs capable of fitting into one shank or handle, and the chances are so many against a lock-picker hitting on the right one.

The first changeable key lock known in England was Day & Newell's "Pneumatic" (inspection-defying) lock, which was brought from America by Mr Hobbs at the time of the 1851 Exhibition, and has been largely used since for banks and other safe. It was fully described in the last edition of this work, and in the books above referred to, but in this place we will describe instead a much simpler form of it, since introduced by Mr Hart of the firm of

Fig. 23.

Hobbs, Hart, & Co. The principle of all changeable key locks is that instead of a single stump fixed to the bolt, there are as many stumps as tumblers, and each one is the projecting part S of a slider PPS which can ride up and down on two pins PP in the bolt, and will stay at any height where it is left when the bolt B is shot. Fig. 23 shows the lock open and the slider stumps lying in the jaws or gating of the tumblers ready to be raised to

any height. In fig. 24 the bolt has been shot, and the sliders coated forward with it. Just before they leave the tumblers they are received by the two small teeth C, O on the frame of the lock, holding each slider at whatever height it may then be, these teeth go right down to the thin part of the bolt or as deep as the sum of all the tumblers and sliders. In this figure the foremost slider is received at its third notch, and each of those below it at some other notch. The tumblers having fallen behind all the stops, the sliders cannot move until the tumblers are all raised again to the various heights at which they left them, which is possible only by the key that locked the lock. These locks have

Fig. 24

Hobbs's protector behind the bolt, and the bit which moves the bolt is behind a revolving curtain (the darkest circle) which is kept steady by one of the tumblers resting on its flattened top. The bolts of the tumblers are shortened, to obviate a certain risk by which one of Newell's locks was picked, but which it is not necessary now to explain. So far as we can judge, this lock has more than all the advantages of that, as it is much less complicated and liable to get out of order from any cause except that to which all locks with spring tumblers are liable, viz., from two tumblers getting stuck together by dirt, so that one of them goes too high with its neighbour. Oiling tumblers is accordingly fatal to them, though it is necessary in other parts of a lock.

The keys of these locks are practically made not of distinct bits screwed into a key frame as in fig. 23, which is the plan used in the Day & Newell lock, and makes a heavy thing to carry, but separate wheels are made, each complete in itself, and fitting into a thickish key pipe which need not be carried about. You may leave it near the safe, and lock up therein, or keep somewhere else, all the bits except the one you use for the day, and carry that in your waistcoat pocket. For such a lock as that described you may have as many of the sixty million bits as you like, and may get new ones from time to time. Or you may have separate bits, as in the paratopic lock, but in that case you must take good care of the key whenever the lock is shut.

The risk of tumblers sticking together in a changeable lock, or any other, may be obviated by not using springs but putting thin plates between the tumblers, as in Sir E. Beckett's lock, giving the tumblers tails coming down on the right of the keyhole in figs. 23, 24, and making the revolving curtain act on all the tails just before the key comes out, by means of an intermediate lever, or else by a small handle which might at the same time bring an escutcheon or external curtain over the keyhole.

Yale Lock

This American lock is remarkable for the smallness of its key, which is shown from *a* to *a* in fig. 25, full size, and is a thin flat piece of steel weighing only 1 of an ounce. The narrowness of the keyhole would be an impediment to introducing a picking instrument together with any other intended at the same time to give a twisting pressure to the small barrel *abc*, which has to turn, as in the Bramah lock, in order to move the bolt, which is not shown in these figures. That may be done either as in Bramah locks or by a tongue or bit attached to the end *ab* of the barrel as in several other locks. The barrel is prevented from being turned,

Fig. 25.

The same company have an entirely different kind of lock from all the preceding ones; it consists of a watch in a case enclosed within the safe door, and has a dial with pins marked for every hour, something like a "toll-tale clock." Any number of these pins can be pulled out a little, and the watch will let a weighted lever fall against the bolts of the safe during all those hours, and hold it up during all the other hours, or *vice versa*. For security the case contains two such watches, so that one may do the work if the other happens to fail. Thus no key is used (except the watch key for winding), but the safe can be opened by a hand moving its bolt at such hours as the watch is set for, and at no other.

It should be added that Mr. Hobbs introduced into England in 1851 the American system of manufacturing every part of a lock by machinery, so that all similar locks of a given size are exactly alike, except the keys, and the gating in the tumblers, which is cut when they are fitted by the key, and even those are done by machinery adjustable to secure what may be called an infinite number of variations. The same system has been introduced in the Government gun-manufacturers, and for clocks and watches, and no hand-wink can compete with it. (E B)

LOCKE, JOHN (1632-1704) Some idea of the man and his surroundings is more needed for the interpretation of what Locke has written than in the case of most philosophers. His youth was spent amidst the war of principles of which England was the scene in the middle of the 17th century. In later life he mixed much with the chief actors in the political drama that followed the Restoration. In his advanced years he was the intellectual representative of tendencies which at the Revolution settlement inaugurated the tranquil material progress and tolerant but more prosaic spirit of the 18th century in England. It is instructive to see how the foundations of belief and the constitution of knowledge are investigated by an English gentleman, who was no reclusive medieval monk or pedantic modern professor, but a man of the world, practically conversant with affairs, in tone calm and rational, and now justly regarded as the typical English philosopher.

Locke was born in the county of Somerset, on the 29th of August 1632, six years after the death of Bacon, and three months before the birth of Spinoza. His father was a small landowner and attorney at Pensford, near the northern boundary of the county, to which neighbourhood the family had migrated from Dorsetshire early in the century. The elder Locke, a strict but genial Puritan, by whom the son was carefully educated at home, was engaged in the military service of the popular party when the son was a boy, Bristol being one of the centres of the war. "From the time that I knew anything," Locke wrote in 1660, "I found myself in a storm which has continued to this time." For fourteen years his education was going on at home, in the Puritan family. The house at Beluton, on his father's little estate, in which these years were spent, may still be seen on the side of one of the orchard-land sales of Somerset, half a mile from the market town of Pensford, and 6 miles from Bristol. The actual place of Locke's birth was at Wrington, 10 miles westward in a house which still exists, where his mother chanced to be on a visit.

In 1646 he entered Westminster School, then of course under Puritan control, and at the headquarters of the parliamentary movement. The six following years were mostly spent there. He does not seem to have liked Westminster, and its memories perhaps produced the bias against public schools which afterwards almost disturbed his philosophic impartiality in his *Thoughts on Education*.

In 1652 Locke passed from Westminster to Oxford. He there found himself at Christ Church, in charge of John Owen, the newly appointed Puritan dean, and vice-chancellor of the university. Christ Church was more or less Locke's home for thirty years. For eight years after he entered Oxford was ruled by the Independents, who, through Owen and Goodwin, unlike the Presbyterians, were among the first in England to promulgate the principles of genuine religious liberty. Locke's hereditary sympathy with the Puritans was gradually lessened by what he saw of the intolerance of the Presbyterians and the fanaticism of the Independents. He found, he says characteristically, that "what was called general freedom was general bondage, and that the popular assertors of liberty were the greatest engrossers of it too, and not unfitted called its keepers." The influence of the liberal divines of the Church of England became apparent afterwards in the progress of his mental history.

Oxford had suffered as a seat of learning during the civil war. Under Owen the scholastic studies and disputations were maintained with a formality unsuited to Locke's free inquisitive temper. The reaction against them which he expressed showed thus early a strong disposition to rebel against empty verbal reasonings. He was not, according to his own account of himself to Lady Masham, a very hard student at first. He sought the company of pleasant and witty men, with whom he likewise took great delight in corresponding by letter; and in conversation and in these correspondences he spent much of his time. He took his bachelor's degree in 1656, and that of master in 1658, the latter on the same day with Joseph Glanville, the author of *Serapis Scientificæ*. In December 1660 he was made tutor of Christ Church, and lectured in Greek, rhetoric, and philosophy in the following year.

At Oxford Locke was within reach of distinctive intellectual influences, then of great strength, and particularly fitted to promote self-education in a strong character. The metaphysical works of Descartes had appeared a few years before he entered Christ Church, and the *Human Nature* and *Leviathan* of Hobbes during his undergraduate years. It does not seem that Locke read extensively, but he was soon drawn to Descartes. The first books, he told Lady Masham, which gave him a relish for philosophical things were those of Descartes. He was delighted in reading them, though he very often differed in opinion from the writer, for he found that what he said was very intelligible. After the Restoration he lived amidst the influences which were then drawing Oxford and England into experimental research. Experiments in physics became the fashion after 1660. The Royal Society was that year founded at Oxford. Wallis and Wilkins, and afterwards Boyle and Wren, at Oxford, and Barrow and Newton at Cambridge, helped to make chemistry, meteorology, and mechanics take the place of verbal disputes. We find him, accordingly, at work in chemistry about 1663, and also in the meteorological observations which always interested him.

The restraints of professional life were not well suited to Locke. There is a surmise that he once contemplated taking orders in the Church of England. His religious disposition attracted him to theological studies. His revulsion from the severe dogmatism of Presbyterians and

the unreasoning fanaticism of Independents favoured that connexion with liberal Anglican churchmen which he maintained in later life. Wheate was his favourite preacher, and latterly his closest intimacy was with the Cadworth family. But, though he has a place among the lay theologians of England, his dislike to ecclesiastical impediments to free research, as well as his taste for experimental investigations, led him in the end to turn to medicine when he had to think about a profession. This was soon after the Restoration, and before 1666 he seems to have been practising medicine in Oxford. But, though afterwards known among his friends as "Doctor Locke," he never graduated as a physician. His health was uncertain, for he suffered all his life from chronic consumption and asthma, and besides that an event soon occurred which withdrew him from medical practice. To the end, however, he was fond of the science, and also ready on occasion to give friendly advice.

Locke had early shown an inclination to politics as well as to theology and to medicine. In 1665 he diverged from medical study at Oxford to diplomacy, and was engaged for a few months in this sort of business, as secretary to Sir Walter Vane on his embassy to Cleves. It was soon after his return from Germany in the following year that the incident occurred which determined his career in the direction of politics. Lord Ashley, afterwards first earl of Shaftesbury, the most truly historical figure among the statesmen of Charles II.'s reign, had come to Oxford for health. There Locke was accidentally introduced to him. This meeting was the beginning of a lasting friendship, sustained by a common sympathy with liberty—civil, religious, and philosophical. In 1667 Locke removed from Christ Church to Exeter House, Lord Ashley's London residence, to become his private secretary, and in 1673 secretary of the Board of Trade. Although he retained his studentship at Christ Church, and occasionally visited Oxford, and also his patrimony at Belton, lately inherited from his father, he found a home and shared fortune with the great statesman during the fifteen years which followed his removal to Exeter House.

The manuscripts of Locke which belong to this Oxford period throw welcome light on the growth of his mind in early life. Among them is an essay on the "Roman Commonwealth," which expresses convictions as to religious liberty and the relations of religion to the state which were only strengthened and deepened in the progress of his life. Objections to the sacerdotal conception of Christianity are strongly stated in another paper; short work is made of human claims to infallibility in the interpretation of Scripture in a third; a scheme of utilitarian ethics, wider in its conception than that of Hobbes, is offered in a fourth. But the most significant of those early revelations is an "Essay concerning Toleration," dated in 1666, which anticipates many of the positions maintained nearly thirty years later in his famous *Letters* on that subject.

The Shaftesbury connexion helped to save Locke from those idols of the den to which professional life in every form is exposed. It brought him much in contact with public men, with the springs of political action, and with the details of office. The place he held as confidential adviser of the greatest statesman of his age is indeed the most remarkable feature in his middle life. Exeter House afforded every opportunity for society, and of this Locke, according to his disposition, availed himself. He became one of the intimates among others of the illustrious Sydenham. But though he joined the Royal Society he seldom went to its meetings, for his custom all his life was to encourage small reunions of intimate friends. One of these at Exeter House was the occasion of the enterprise

which has made his name memorable in history, for it was there that "five or six friends" met one evening in his rooms, about 1671, and discussed "principles of morality and religion" which seemed remote from questions about "human understanding." They "found themselves quickly at a stand by the difficulties that arose on every side." Locke suggested a careful examination of the exact limits of man's power to know the universe as the proper way out of their difficulties. The results of the reflexion to which these difficulties thus gave rise, he thought, when he set to work, might be contained on "one sheet of paper." But what was thus "begun by chance was continued by contrasty, written by incoherent parcels, and after long intervals of neglect resumed again as humour and occasions permitted," till at last, at the end of nearly twenty years, it was given to the world as the *Essay on Human Understanding*. This work gave intellectual unity and a purpose to his life as a man of letters and philosophy.

The fall of Shaftesbury in 1675 enabled Locke to escape for four years from the centre of English politics to a retreat in France, where he could unite the study of "human understanding" with attention to health. He spent three years partly at Montpellier and partly in Paris. His journals and commonplace books of this period show the *Essay* in process of construction. The visits to Paris were times of meeting with men of letters and science, among others Gassendi, the well-known Amsterdam physician; Romer, the Danish astronomer; Thoyard, the critic; Thieriot, the traveller; Justel, the jurist; and Bernier, the expatriate of Gassendi. There is no mention of Malebranche, whose *Recherche de la Vérité* had appeared three years before, and who was then at the Oratoire, nor of Arnauld, his illustrious rival at the Sorbonne.

Locke returned to London in 1679. A reaction against the court party had for a time restored Shaftesbury to power. Locke resumed his old confidential relations. A period of much-interrupted leisure followed. It was a time of plots and counterplots, when England seemed on the brink of another civil war. In 1680 and Shaftesbury was committed to the Tower, tried, and acquitted. More insurrectionary plots followed in the summer of 1682, after which, isolated at home, he escaped to Holland, and died at Amsterdam in January 1683. In these two years Locke was much at Oxford or at Belton. The last movements of Shaftesbury did not recommend themselves to the sage caution of his secretary. "The officials of Government kept their eyes on him. 'John Locke lives a very cunning unattainable life here,' Pridemore reported from Oxford in 1682. 'I may confidently affirm,' the dean of Christ Church afterwards wrote to Lord Sunderland, 'there is not any one in the college who has heard him speak a word against, or so much as censuring, the Government; and, although very frequently, both in public and private, discourses have been purposely introduced to the disparagement of his master, the earl of Shaftesbury, he could never be provoked to take any notice, or discover in word or look the least concern; so that I believe there is not in the world such a master of taciturnity and passion.' Some unpublished correspondence with his Somerset friend, Edward Clarke of Chipley, describes his daily life in these troubled years, and refers to intercourse with the Cudworth family, who were intimate with the Clarkes. The commonplace books and letters about the same time allude to toleration in the state and comprehension in the church, and show an indifference to questions on which theological disputers lay stress, hardly consistent with a strict connexion with any organized body of Christians, notwithstanding his gravitation towards the Church of England as the most liberal community.

In his fifty-second year, in the gloomy autumn of 1683,

Locke retired to Holland in voluntary exile. It was then the asylum of eminent persons who were elsewhere denied civil and religious liberty. Descartes and Spinoza had meditated there; it had been the home of Erenus and Orotius; it was now the refuge of Bayle. Holland was Locke's sanctuary for more than five years; but it was hardly a voluntary retreat. His (unpublished) letters from thence represent a man of tender feelings, on whom exile sat heavily. Amsterdam was his first Dutch home. For a time he was in danger of arrest at the instance of the English Government. After anxious months of concealment in the houses of friends, he escaped; he was, however, deprived of his citizenship at Christ Church, and Oxford was finally closed against him by order of the king. But Holland introduced him to new friends. One of these, ever after an intimate correspondent, was Philip van Limborch, the successor of Episcopius as Remonstrant professor of theology, lucid, learned, and tolerant, the friend of Cudworth, Whiclocke, and More. Limborch attached him to Le Clerc, then the youthful representative of letters and philosophy in Limborch's college, who had escaped from Geneva and Calvinism to the milder atmosphere of Holland. The *Bibliothèque Universelle* of Le Clerc, commenced in 1686, soon became the chief organ in Europe of men of letters. Locke was at once united with him in the work, and contributed several articles. It was his first appearance as an author, although he was now more than fifty-four years of age, and afterwards produced so many volumes. This tardiness in authorship is a significant fact in Locke's mental history, in harmony with the tempered wisdom and massive common sense which reign throughout his works. The next fourteen years were those in which the world received the thoughts which observation of affairs and reflexion had so long been forming in his mind. They were taking shape for publication while he was in Holland. The *Essay* was finished there, and a French epitome of it appeared in 1688, in Le Clerc's journal. Locke was then at Rotterdam where he lived for more than a year in the house of a Quaker friend, Benjamin Farley, a wealthy merchant and collector of books. The course of affairs in England at last opened a way for his return to his native country. At Rotterdam he was the confidant of the political exiles, including Burnet and Mordaunt, afterwards the famous earl of Peterborough, as well as of the prince of Orange. William landed in England in November 1688; Locke followed in February 1689, in the same ship with the princess of Orange and Lady Mordaunt.

It was after his return to England that through authorship Locke emerged into European fame. Within a month he had declined the embassy to Brandenburg, and taken instead the modest office of commissioner of appeals with its almost nominal duties. The two years, 1689 and 1690, during which he lived at Dorset Court, in London, was memorable for the publication of his two chief works in social polity, and also of the most popular and widely influential book in modern philosophy, which expresses in a generalized form the principles that lie at the root of all his political and other writings. The first of the three to appear was the defence of religious liberty in the state, in the *Epistola de Tolerantia*, addressed to Limborch. It was published at Gouda in the spring of 1689, and translated into English in autumn by William Popple, a Unitarian merchant in London. The *Two Treatises on Government*, in defence of the sovereignty of the people, followed a month or two after. The *Essay concerning Human Understanding* saw the light in the spring of 1690. He received £30 for the copyright, which was nearly the same as Kant afterwards got for the first edition of his *Kritik der reinen Vernunft*. He had carried the manuscript

from Holland, ready for the press except a few last touches. It was the first book in which his name appeared, for the other two were published anonymously.

Locke's asthma and other ailments had increased in the latter part of 1690. The air of London always aggravated them. The course of public affairs also disappointed him, for the settlement at the Revolution in many ways fell short of his ideal. It was then that the home of his old age, the brightest of all his homes, opened to receive him. This was the manor house of Oates in Essex, pleasantly situated midway between Ongar and Harlow, the country seat of Sir Francis Masham. Lady Masham was the accomplished daughter of Cudworth, and Locke had known her before he went to Holland. In the course of the two years after his return, she told Le Clerc, "by some considerably long visits Mr Locke made trial of the air of this place, which is some 20 miles from London, and he thought that none would be so suitable for him. His company could not but be very desirable for us, and he had all the assurances we could give him of being always welcome; but, to make him easy in living with us, it was necessary he should do so on his own terms, which Sir Francis at last assenting to, he then believed himself at home with us, and resolved, if it pleased God, here to end his days—as he did." It was in the spring of 1691 that this idyllic life at Oates began. There, among the green lanes of rural England, he enjoyed for fourteen years as much domestic peace and literary leisure as was consistent with broken health and sometimes anxious visits to London on public affairs. Oates was in every way his home. In his letters and otherwise we have charming pictures of its inmates and its internal economy, as well as of occasional visits of friends who went there to see him, among others Lord Peterborough and the Lord Shaftesbury who wrote the *Characteristics*, Isaac Newton, William Molyneux, and Anthony Collins.

At Oates he was always busy with his pen. The *Letter on Toleration* had already involved him in controversy. The answer of a certain Jonas Frost of Queen's College, Oxford, had drawn forth in 1690 his *Second Letter on Toleration*. A rejoinder in 1691 was followed by Locke's *Third Letter* in the summer of the following year. And other questions divided his interest with this one. In 1691 those of currency and finance were much in his thoughts; in the year after he addressed a letter to Sir John Somers on the *Consequences of the Lowering of Interest and Raising the Value of Money*. It happened too that when he was in Holland he had written letters to his friend Clarke of Chipley about the education of his children. These letters formed the substance of the little volume that appeared in 1693, entitled *Thoughts on Education*, which still holds its place among the classics in that department. Nor were the "principles of revealed religion" forgotten, which a quarter of a century before were partly the occasion of the *Essay*. The circumstances of the time now made him desire to show how few and simple all the essential points held in common by the religious community of England were, and to bring men if possible to agree to differ as individuals regarding all beyond. The issue was an anonymous essay on the *Reasonableness of Christianity as delivered in the Scriptures*, which appeared in 1695, in which Locke tried to separate the divine essence of Christianity from accidental accretions of dogma, and verbal reasoning of professional theologians, ignorant of the limits within which the conclusions of human beings on such subjects must be confined. This renunciation involved him in controversies that lasted for years. A host of angry polemics assailed the book. A now forgotten John Edwards was conspicuous among them. Locke produced a *Vindication* which added fuel to the fire,

and was followed by a *Second Vindication* in 1697. Notes of opposition to the *Essay* too had been heard almost as soon as it appeared. John Norris, the metaphysical rector of Banerston, an English disciple of Malebranche, criticized it in certain *Curvey Refutations* in 1690. Locke took no notice of this at the time, but his second winter at Oates was partly employed in writing what appeared after his death as an *Examination of Malebranche's Opinion of Seeing all Things in God*, and as *Remarks upon some of Mr Norris's Books*,—tracts which throw important light upon his own theory, or rather want of theory, as to perception through the senses. When he was examining Malebranche he was also preparing the *Essay* for a second edition, and corresponding with his friend William Molyneux at Dublin about amendments in it. This edition, with a chapter added on "Personal Identity," appeared in 1695. It was followed by a third, which was only a reprint, later in the same year. Wynne's well-known abridgment in that year helped to make the book known in Oxford, and Molyneux had years before introduced it in Dublin. In 1695 a return to questions about the currency diverted Locke's attention for a little from metaphysics and theology. Circumstances in that year gave occasion to his tract entitled *Observations on Silver Money* and also to his *Further Considerations on Raising the Value of Money*.

In 1696 Locke was induced to accept a commissionership on the Board of Trade, which made frequent visits to London needful in the four following years, and involved him considerably in the cares of office. Meantime the *Essay on Human Understanding* and the *Reasonableness of Christianity* were both becoming more involved in the world warfare between dogmatists and latitudinarians, trinitarians and unitarians, of which England was the scene in the last decade of the 17th century. The controversy with Edwards was followed by another with Stillingfleet, bishop of Worcester, which takes its place among the memorable philosophical controversies of the modern world. It arose in this way. John Toland, an Irishman, in his *Christianity not Mystical*, had exaggerated some passages in the *Essay*, and then adopted the opinions as his own. In the autumn of 1696, Stillingfleet, who was a learned and argumentative ecclesiastic more than a religious philosopher, in a *Vindication of the Doctrine of the Trinity* wrote some pages on Locke, condemning him especially for eliminating mystery from human knowledge in his account of what is meant by "substance." Locke replied in a *Letter* dated January 1697. Stillingfleet's rejoinder appeared in May, followed by a *Second Letter* from Locke in August, to which the bishop replied in the following year. Locke's elaborate *Third Letter*, in which the ramifications of the controversy are pursued with a tedious expenditure of acute reasoning and polished irony, was delayed till 1699. The death of Stillingfleet in that year brought this famous trial of strength to an end. (The interesting episode of Molyneux's visit to Oates, followed by his death a few days after his return to Dublin, occurred in 1698, when the Stillingfleet controversy was at its height.) Other critics were now entering the lists against the *Essay*. One of the ablest was John Sergeant, a Catholic priest, in his *Solid Philosophy Asserted Against the Fancies of the Idealists*, in 1697. He was followed by Thomas Burnet and Dean Sherlock. Henry Lee, rector of Trichmarsh, produced in 1702 a folio volume of notes on each chapter in the *Essay*, under the title of *Anti-Scepticism*; John Broughton dealt another blow in his *Psychologia* in the following year. About the same time too John Norris returned to the attack, in various passages in his *Theory of the Ideal or Intelligible World*. Locke was defended with vigour by Samuel Bodke, a Dorsetshire

clergyman. The *Essay* was all the while spreading over Europe, impelled by the great name of its author as the chief friend and philosophical defender of civil and religious liberty. The fourth edition (the last while Locke was alive) appeared in 1700. It contained two important new chapters on "Association of Ideas" and "Enthusiasm." What was originally meant for a third chapter was prepared but withheld. It appeared among Locke's posthumous writings, under the now well-known title of *Conduct of the Understanding*, in some respects the most characteristic of his works. The French translation of the *Essay* by Pierre Coste, Locke's amanuensis at Oates, was almost simultaneous with the fourth edition. The Latin version by Burridge of Dublin appeared the year after, reprinted in due time at Amsterdam and at Leipzig.

After 1700 Locke was gathering himself up for the end, in the rural repose of family life at Oates. The commission at the Board of Trade was resigned, and the visits to London ceased. Scriptural studies and religious meditation engaged most of his available strength in the four years that remained. The Gospels had been much searched by him when he worked in theology years before. He now turned to the Epistles of St Paul, and applied the spirit of the *Essay*, and the rules of critical interpretation which apply to other books, to interpret a literature which he still venerated with the submissiveness of the pious Puritans who surrounded his youth. The results of these studies were ready for the printer when he died, and were published about two years afterwards. A few pages on *Miracles*, written in 1702, in connexion with Fleetwood's essay, also appeared posthumously. More adverse criticism was now reported to him, and the *Essay* was formally condemned by the authorities at Oxford. "I take what has been done rather as a recommendation of the book," he wrote to his young friend Anthony Collins, a neighbouring Essex squire, then a frequent visitor at Oates, and afterwards a leader of free thought, "and when you and I next meet we shall be merry on the subject." One attack only moved him. In 1704 his adversary Jonas Proast unexpectedly revived their old controversy. Locke in consequence began a *Fourth Letter on Toleration*. The few pages in the posthumous volume, ending in an unfinished sentence, seem to have exhausted his remaining strength in the weeks before he died. Thus the theme which had employed him at Oxford more than forty years before, and had been his ruling idea throughout the long interval, was still dominant in the last days of his life. All that summer of 1704 he continued to decline, tenderly nursed by Lady Masham and her step-daughter. On the 28th of October he passed away, as he declared, "in perfect charity with all men, and in sincere communion with the whole church of Christ, by whatever names Christ's followers call themselves." The tomb of Locke may be seen on the south side of the parish church of High Laver, in which he often worshipped, near the tombs of the Mashams, and of Damaris, the widow of Oudworth, bearing a Latin inscription prepared by his own hand. At the distance of a mile are the garden and park where the manor house of Oates once stood, surrounded by a green undulating country, in the lanes of which the slender delicate figure, with the refined reflective countenance made familiar to us by Kneller, was so often seen in the last years of the 17th century.

Locke's history, combined with his writings, has made his intellectual and moral features not less familiar. The reasonableness of taking probability for our ultimate guide in all the really important concerns of life was the essence of his philosophy. The desire to see for himself what is really true in the light only of its reasonable evidence, and that others should do the like, was his ruling passion, if

the term can be applied to one so calm and judicial. "I can no more know anything by another man's understanding," he would say, "than I can see by another man's eyes." The knowledge which one man possesses is "a treasure which cannot be lent or made over to another." This repugnance to believe blindly what rested on authority, as distinguished from what was seen to be sustained by self-evident reason or by demonstration or by good probable evidence, runs through his life. He is typically English in his reverence for facts, whether facts of sense or of rational consciousness, in his tendency to turn away from purely abstract speculation and merely verbal reasonings, in his suspicion of mysticism, in his calm reasonableness, and in his ready submission to truth, even when the truth was incapable of being reduced to system, provided only that it served a human purpose. The delight he took in making use of his reason in everything he did, and a wise use of it too, was what his friend Pierre Coste found most prominent in Locke's daily life at Oates. "He went about the most trifling thing always with some good reason. Above all things he loved order, and he had got the way of observing it in everything with wonderful exactness. As he always kept the useful in his eye in all his disquisitions, he esteemed the employments of men only in proportion to the good they were capable of producing, for which cause he had no great value for the critics who waste their lives in composing words and phrases, and in coming to the choice of a various reading in a passage that has after all nothing important in it. He cared yet less for those professed disputants who, being taken up with the desire of coming off with victory, justify themselves behind the ambiguity of a word, to give their adversaries the more trouble. And whenever he had to deal with this sort of folks, if he did not beforehand take a strong resolution of keeping his temper, he quickly fell into a passion, for he was naturally choleric, but his anger never lasted long. If he retained any resentment it was against himself, for having given way to so ridiculous a passion, which, as he used to say, may do a great deal of harm, but never yet did any one the least good." Large, "round-about," even prosaic common sense, with intellectual strength solidly directed by a virtuous purpose, much more than subtle or daring speculation sustained by an idealizing faculty, in which he was deficient, is what we find conspicuous in Locke's conduct, correspondence, and books. A defect in speculative imagination undoubtedly appears when he encounters the vast and complex problem of human knowledge in its organic unity, and when he is obliged to recognize the need for philosophy as an additional inquiry to that within the scope of any one, or all, of the special sciences.

In the inscription on his tomb Locke refers to his printed works as the true representation of what he really was. They are concerned with SOCIAL POLITY, CHRISTIANITY, EDUCATION, and PHILOSOPHY. It may be convenient to arrange them under these four heads, in the order in which they were published, and then to give some account of his opinions under each head.

I. SOCIAL POLITY.—(1) *Apologia de Tolerantia*, 1689 (translated into English in the same year) (2) *Two Treatises on Government*, 1690 (the *Patriarcha* of Filmer, to which the *First Treatise* was a reply, appeared in 1680) (3) *A Second Letter concerning Toleration*, 1690 (4) *Some Considerations on the Consequences of Lowering the Rate of Interest and Raising the Value of Money*, 1691. (5) *A Third Letter for Toleration*, 1692. (6) *Short Observations on a printed paper entitled, "For Encouraging the Coining of Silver Money in England, and after for Keeping it here,"* 1696. (7) *Further Considerations concerning Raising the Value of Money*, 1696 (this was occasioned by a Report containing an "Essay for the Amendment of Silver Coins," published that year by William Lowndes, a secretary for the Treasury; Locke anticipates some later views in political economy). (8) *A Fourth Letter for Toleration*, 1706 (posthumous).

II. CHRISTIANITY.—1. *The Reasonableness of Christianity as delivered in the Scriptures*, 1666. (2) *A Vindication of the Reason-*

abilities of Christianity from Mr. Bouverie's *Reflections*, 1695. (3) *A Second Publication of the Reasonableness of Christianity*, 1697. (4) *A Paraphrase and Notes on the Epistles of St. Paul to the Galatians, First and Second Corinthians, Romans, and Ephesians. To which is prefixed an Essay for the understanding of St. Paul's Epistles by consulting St. Paul himself*, 1705-7 (posthumous).

(5) *Education*, 1693. (6) *Thoughts concerning Education*, 1693. (7) *The Conduct of the Understanding*, 1706 (posthumous). (8) *Some Thoughts concerning Reading and Study for a Gentleman*, 1706 (posthumous). (9) *Instructions for the Conduct of a Young Gentleman*, 1706 (posthumous). (10) *Of Study* (written in France in Locke's journal, and published in L. King's *Life of Locke* in 1830).

(11) *Posthumous*.—(1) *An Essay concerning Human Understanding*, in four books, 1689. (2) *A Letter to the Bishop of Worcester concerning some passages relating to Mr. Locke's Essay of Human Understanding in a late Discourse of his Lordship's in a Publication of the Trinity, 1697*. (3) *Mr. Locke's Reply to the Bishop of Worcester's Answer to his Letter*, 1697. (4) *Mr. Locke's Reply to the Bishop of Worcester's Answer to his Second Letter*, 1699. (5) *A Discourse of Miracles*, 1706 (posthumous). (6) *An Examination of Father Malebranche's opinion of Something else than God*, 1706 (posthumous). (7) *Remarks upon some of Mr. Norris's Books, wherein he asserts Father Malebranche's opinion of Something else than God*, 1720 (posthumous).

The following are Miscellaneous Tracts:—(1) *A New Method of a Common Place Book*, 1686 (this was Locke's first article in the *Bibliothèque de La Clero*, his other contributions to it are uncertain, except the *Epistola de Usu*, in 1688). (2) *The Fundamental Constitutions of Carolina* (prepared when Locke was Lord Shaftesbury's secretary at Exeter House about 1673; remarkable for its recognition of the principle of toleration, and published in 1708, in the posthumous collection). (3) *Notes relating to the Life of Anthony, First Earl of Shaftesbury*, 1706. (4) *Elements of Natural Philosophy*, 1706. (5) *Observations upon the Growth and Culture of Vines and Olives*, 1706. (6) *Rules of a Society which met once a Week, for their improvement in Useful Knowledge, and for the promotion of Truth and Christian Charity*, 1706. (7) *A Letter from a Person of Quality to his Friend in the Country*, published in 1755 (included by Des Maizeaux in his *Collection of Several Pieces of Mr. John Locke*, 1750), and soon afterwards burned by the common hangman by orders from the House of Lords, was disavowed by Locke himself. It may have been dictated by his amanuensis.

There are also various writings of Locke first published in the biographies of Lord Haig and of Mr Fox Bourne.

Locke's numerous letters to Thoynard, Lamborch, Le Clero, Guendouin, Moyleux, Collins, Sir Isaac Newton, the first and the third Lord Shaftesbury, Lord Bolingbroke, the Countess of Clifley, and others, many of them unpublished, are models in their kind. They express the courtesy and humour which were natural to him, and his varied interests in human life. These to Moyleux and Lamborch in particular throw light on the *Essay*, and his works on Toleration and Christianity.

It has been truly said that all Locke's writings, even the *Essay on Human Understanding* itself, were "occasional, and intended directly to counteract the enemies of reason and freedom in his own age." This is obviously true of his works on Social Policy, written in an age when the principles of democracy and toleration were struggling with passive obedience and divine right of kings, and when even "the popular assertions of public liberty were the greatest engrossers of it too." The state with Locke was the issue of free contract, and was not a natural organism. That the people, in the exercise of their sovereignty, have the right to govern themselves in the manner they judge most conducive to their common good, and that the civil government, whatever form it assumes, has no right to interfere with religious beliefs not expressed in actions inconsistent with civil society, is the essence of his political philosophy. He based the ultimate sovereignty of the people on a virtual consent or compact between the people themselves and the government. The precise terms of contract, he allowed, might and should be modified by the sovereign people from time to time, in accommodation to ever changing circumstances. He saw that things in this world were in so constant a flux that no society long remained in the same state, and that "the greatest inconveniences must be the issue of a following custom when reason has left the custom." With an English love of compromise in the working of political affairs, he was always disposed towards liberal ecclesiastical concessions for the sake of religious unity and peace, and recommended obedience to the civil magistrate in all indifferent things in worship and government, not otherwise expressly determined by supernatural revelation.

His attack on Sir Robert Filmer in the *First Treatise on Government* was an anachronism, even when it was published; in the democratic principle argued for in the *Second Treatise*, while in advance of the practice of his age, was he over-reacted by Aquinas and Bodin, as well as by Grotius and Hooker. His philosophical defence of the social rights of religious beliefs was the most original

and important of his contributions to polity, and the most far-reaching in its ultimate assumptions. Locke held a more modest estimate of human resources, natural and supernatural, for forming true judgments in religion, and a less pronounced judgment of the immorality of religious error, than either the Catholic or the Puritan.

The toleration which he spent his life in arguing for meant a revolution from the absolute to a relative point of view in the theory of knowledge. It was a protest against those who in theology "peremptorily require demonstration, and demand certainty where probability only is to be had." The practice of universal toleration without increasing religious differences was the most important application to the circumstance of his own age of the theory about human knowledge which pervaded his *Essay*. This paradox is now a commonplace, and the superabundant argument and irony in the *Lettres on Toleration* fatigue the modern reader.

The change of opinion as more due to Locke himself than to any one else. "The rights of free thought and liberty of conscience had indeed been pleaded for, on various grounds, throughout the century in which he lived. Chillingworth, Jeremy Taylor, Cudworth, Glanville, and other philosophical thinkers in the Church of England urged toleration in the state, in conjunction with a wide comprehension in the church, on grounds which implied intellectual limitation and even uncertainty in religious matters. Puritan Independents and Baptists, like Owen, Goodwin, and Richardson, whose idea of ecclesiastical comprehension was dogmatic and narrow, were ready to accept sectarian vanity within the state, on the ground that it was possible to have many religions in the land, but only their own form within their sects." The existence of separate Christian nationalities, on the other hand, was the only justification of separate religious societies to the latitudinarian churchmen with whom Locke associated; in each nationality they would have a comprehensive church co-extensive with the nation.

Locke went far to unite in a higher principle what was best in the broad Anglican and in the Puritan theories, while he recognized the individual liberty which has ever distinguished the national church of England. (a) In his reasonings for toleration he insists on the fact that all human theologies must consist more of beliefs determined on presumptions of probability than of knowledge founded on facts, either self-evident or demonstrable in the light of reason. A profound sense of the limits of human reason was at the bottom of his arguments for a tolerant comprehension by the state and also by the church. He had no objections to a national establishment of some form of religion, provided it was conducted with tolerance, and was really the nation organized to promote goodness, and not to protect the metaphysical subtleties by which professional theologians spoil the original simplicity of Christianity.

The recall of the national religion to this primitive simplicity, he hoped, would make a nation of accommodation unnecessary, as few would then remain to ask for it. (2) The speculative, and the metaphysical, and the socially harmless, nature of most presented beliefs and forms of worship is another point on which he insists. "No man is hurt because his neighbour is of a different religion from his own, and civil society is hurt because its members are of different religions from one another." The more various our beliefs are, the more probable it becomes that a complete view of truth may by degrees be reached at last by the human race. In the meantime beliefs in religion concern the individual only and not society. To the atheist alone Locke absolutely refuses toleration, on the ground that the soul bonds can have no hold over him, for "God is taking away of God himself all."

If atheism means the denial that reason is the ultimate regulative principle in the universe, then the consistent atheist without doubt "dissolves all," and must reject physical science even, as well as morality, in an absolute ascension, so that he is incapable of citizenship as one who is insane. In Locke's own philosophy, as we shall see, the case of God is equally strong, but not demonstrable, but the distinctive articles of Christianity are founded only on presumptions of probability. He argued too against full toleration to the Church of Rome, at least in the circumstances of the age in which the Toleration Act was passed, on the ground of its subsistence to a foreign sovereign.

(3) The infiniteness of force as a means of bending the light of truth into human minds is a third argument urged by Locke, founded on the psychology of human understanding. Persecution can only transform a man into a hypocrite, belief must be formed by individual discernment of evidence. Apart from evidence, a man cannot command his own understanding, he cannot determine arbitrarily what opinions he is to hold. Thus all Locke's pleas for a universal toleration resolve at last into a philosophical view of the limits and origin of knowledge.

It is the principles which determined Locke's social polity largely determining his way of looking at Christianity. His "institutionalism" was really the result of an extraordinary reverence for truth, and of his perception that in matters of religion knowledge may be sufficient for practice while it falls far short of perfection and demonstration. He insists on referring questions in religion to the reasoning individual, and never loses sight of the essential reasonableness of Christianity as the only ground on which it

can rest. Locke accepted the Scripture as infallible with the reverence of a Puritan, but he did not, like so many Puritans, mean only Scripture as interpreted by himself. Confidence in Biblical infallibility was also combined in Locke with a distrust in the pretensions of "enthusiasm," which predisposed him to regard miracles as a criterion needed for distinguishing reasonable religious convictions from mere "impressions, fancies, and strong senses." Assent in religion as in every thing else he could only justify on the grounds of its evident rationality: "illumination without search, and certainty without proof and without examination," was to him a sign of the absence of the divine spirit. Fanatical confidence that we are right, he says, "is to be judged by the doctrine, and not the doctrine by the miracles." All this sort of argument became commonplace in books about the "evidences" in the 18th century. The *Reasonableness of Christianity* was an attempt to recall religion from verbal reasonings of theological schools, destructive of peace among Christians, to its original simplicity, but it no doubt involved an abatement of its transcendent mystery and ultimate incomprehensibility. The book was probably written to promote a comprehension of the dissenters. All who practically acknowledge the supremacy of Jesus as the Messiah accept all that is essential to the Christianity of Locke, whatever other theological opinions they may individually or collectively add to this only catholic one.

Christian teachers and apologists at the succeeding age, as well as the assailants of Christianity, alike appealed to the *Essay on Human Understanding*, and the catholic tradition of Anglican theology was thus interrupted in the church for more than a hundred years. The confusion, anxiety and earnestness, were more the outcome of the sort of common sense sagacity which through him moulded the prudential theology of England in the 18th century, than of the nobler elements present in More, Cudworth, and other religious philosophers of the preceding age, or afterwards in Latimer and Schlegel.

III. Locke takes his place in the succession of great writers on the theory and art of Education. His educational writings might be regarded either as an immediate introduction to or as an application of the *Essay on Human Understanding*. In his *Thoughts on Education* imagination is stimulated to new activity as weigh against prudential utilitarianism; information and mere learning are subordinated to the formation of character and practical wisdom; the part which habit plays in individuals is always kept in view; the dependence of conscious mind, which it is the purpose of education to improve, upon the health of the corporeal organism is steadily indicated; to make those happy who are undergoing education is a favourite precept; accumulating facts in the memory without using the power to think, and without accompanying the youthful mind to apply reason to the evidence by which individual thoughts must be tested, is always referred to as the cardinal vice in teaching. "Wisdom more than learning is what he requires in the teacher. In the knowledge to be communicated he gives the first place to "that which may direct us to heaven," and the second to "the study of prudence, or discreet conduct and management of ourselves in the several occurrences of our lives," which most assists our present prosperity and the enjoyment of the present life. The infancy of knowable existence in contrast with the narrowness of human understanding and experience is always in his thoughts. This "disproportionateness" is one reason given for due deliberation in the choice of studies, and for declining those which lie out of the way of a really wise man, however much they may have been favoured by custom. Among the things he warns especially against "that mass of words and phrases which have been employed only to instruct and amuse people in the art of disputing, and which will be found perhaps, when looked into, to have little or no meaning, . . . words being of no value nor use, but as they are the signs of things, when they stand for nothing more, or less than clear ideas, for instead of representing the value of those they are joined with, they lessen it and make it nothing." Knowledge of what the opinions of other men have been is another study which Locke depreciates. "Truth needs no recommendation, and error is not mended by it; in our inquiry after knowledge it hinders concerns us to know what other men have thought."

It is an idle art, he says, to make it one's business to study what have been other men's sentiments in matters where reason is only to be judge. Realism and individual rationality are two essential educational principles with Locke. In his *Conduct of the Understanding* the pupil is to be led to the point at which "a full view of all that relates to a question" is to be had, and at

which alone a rational discernment of the truth is possible. The unmediated mass of material, on the contrary, rather than reason at all, or else "put passion in the place of reason," or "for want of large, sound round-about sense" they direct their minds only to one part of the evidence, "converse with one sort of men, read but one sort of books, and will not come in the hearing of but one sort of notions, and so carry out to themselves a little Goshawk in the intellectual world, where light shines, and, as they conclude, day blesses them; but the rest of the vast expanse they give up to night and darkness, and avoid coming near it." It is a tissue on the wisdom needed for the management of the individual mind, so as to that it may overcome the *idola* or common tendencies to error against which Bacon had warned mankind, that requires judgment, bias, or want of a *prætor*, "indifference" to what evidence may require us to conclude, undue regard for authority or love for custom and antiquity, indolence and sceptical despair, are among the states of mind marked by him, as most apt to interfere with the formation of our individual thoughts in harmony with the Universal Thought that is latent in nature. The development of vigorous intellect in each person is the aim of this admirable tract.

IV. The *Essay Concerning Human Understanding* contains Locke's Metaphysical Philosophy. It was the first attempt, on a great scale, and in the Baconian spirit, to show the certainty and inadequacy of human knowledge. This enterprise seemed to Locke to hold out the most reasonable hope of a solution of some sort for the perplexities which encompassed every department of inquiry.

The Introduction to the *Essay* is the keynote to the whole. The ill fortune of mankind in their endeavour to comprehend themselves and their surroundings is there attributed to their disposition to extend their inquiries into matters beyond the reach of our intelligence, letting their thoughts wander into depths where we can have no footing. "Whereas, were the capacities of our understandings well considered, the extent of our knowledge once discovered, and the horizon found which sets the bounds between the enlightened and the dark parts of things, between what is and what is not comprehensible by us, men would perhaps with less acute sequences in the avowed ignorance of this one, and employ their thoughts in more advantage in the search of the other." To inquire into "the original, certainty, and extent of human knowledge, together with the grounds and degrees of belief, opinion, and assent," is Locke's own account of the design of his *Essay*. He expressly excludes from his inquiry "the physical causes of the mind,"—the nature, cause, and extent of the faculties, and the transcendental reasons for our conscious experience being what in his own "plain historical method" he might find it to be. He wanted to be able to make a faithful report, based on what he actually found, as to how far a merely human understanding of the universe could extend, to what extent, and how far it fell short of pure knowledge, and in what cases they can only judge and guess "on grounds of probability. Although his report might show that the knowledge attainable by the individual must be "narrow," and far short of a "universal or perfect comprehension of whatsoever is," it might also convince us that it is "sufficient," because "suited to our individual state." The "light of reason," the "candle of the Lord" that is set up in us, "shines bright enough for all our purposes. If we will disabuse every thing because we cannot certainly know all things, we shall do much as wisely as he who would not see by his legs, but sit still and perish because he had no wings to fly." Locke thus opens his *Essay* in a tone which, with a more homely cheerfulness, reminds one in parts of the sublime conceptions of Pascal, and in others of the wise moderation of Bishop Butler. The outcome is that, if it should turn out on investigation that human understanding cannot solve the metaphysical problem of the universe, we may at least find that at no stage of our individual existence are we the sport of chance or of an evil power,—that there is a way by which we can secure our final wellbeing, even within the inexorable causal connexions, conditioned by space and time, and which their imperfectly calculable issues, by which we are surrounded.

The fourth book alone is concerned directly with the professed design of the *Essay*. It has been suggested by Stewart that Locke may have commenced with this book, especially as it contains few references to preceding parts of the *Essay*, so that "it might have been published separately without being intelligible than it is." The inquiries in the preceding books are of a more abstract and scholastic nature, which probably opened gradually on his mind as he studied his subject more closely. The second and third books both relate to our individual ideas or thoughts. That each person has thoughts, and that without thoughts or consciousness there could be no knowledge for him, is a *Lockian* postulate. That we pre-exist, "will be easily granted," for "every one is conscious of ideas in himself, and men's words and actions will satisfy him that they are in others." Questions about knowledge and its extent therefore presuppose questions about ideas or thoughts. But our most ideas are, as Locke reminds us, "ideas of sense, or of reflection, being nothing but bare appearances in our own minds." Truth

and falsehood belong only to the assertions or denials of the mind. The idea of a centaur has no more falsehood in it, when it appears in our minds, than the name centaur has falsehood in it when it is pronounced by our mouths, or written on paper. Truth and falsehood lie always in affirmations or negations, and the mere thoughts of which as individuals we happen to be conscious are not proper either true or false. They do not become either real knowledge or error "till the mind affirms or denies something of them."

That none of our knowledge is "innate" is the conclusion argued for in the First Book. But the drift of this famous argument has been overlooked by Locke's critics. It has been conceived as if it was a metaphysical disquisition about the existence of transcendental elements in human knowledge, like that at issue in the present day between empiricism and intellectualism. If it were so it would be an example of the fallacy of irrelevant conclusion. For this Locke himself is no doubt verily responsible. It is not easy to determine who or what he had in view in this polemic. Lord Herbert alone is made prominent as the defender of innateness, and Locke was perhaps too little led in the literature of ancient and modern philosophy to do full justice to those who, from Plato downwards, have recognized the intuitions of reason as well as the phenomena of sense in the constitution of knowledge. The positions which he assails would have been disclaimed by the most eminent defenders of the transcendental elements. "Innates," as Lord Shaftesbury says, "is a word Mr. Locke poorly plays on,"—at least if he is to be understood as engaged in an intellectual struggle against Plato or Descartes. "The right word, though less used, is *conscientia*. For what has birth, or the progress of the fœtus, to do in this case?" The real question, as Shaftesbury adds, is not about the time when the supposed innate knowledge entered, but "whether the constitution of man be such that, being adult and grown up, the ideas of (rational) order and administration of a God will not infallibly and necessarily spring up in him." But this Locke himself does not deny. "That there are certain propositions," we find him saying, "which, though the soul from the beginning, or when a man is born, does not know, yet, by assistance from the outward, and the help of some previous cultivation, it may afterwards come certainly to know the truth of, as no more than what I have affirmed in my first book" (see "Epistle to Reader," in second edition). This further appears from the fact that, although the *Essay* opens with an attack on innateness in human nature, yet the self-evident, in the light of educated instincts of much that we know is asserted elsewhere not less strenuously. Much of our knowledge he reports in the fourth book to be reached by purely rational insight and demonstration. What he really argues against in the first book is that any of it should be supposed to have a claim to protection against a free criticism of its reasonableness. He argues there against the innateness of our knowledge of God and of morality; yet in the fourth book he reports, as a result of his search into our rational consciousness, in the "plain historical method," that the evidence of God is a demonstrable rational conclusion, involved in that causal necessity without which there could be no knowledge at all; and he maintains in various places that morality may be found to be as demonstrably necessary as mathematics. The two positions are quite consistent. The demonstrable rational necessity of these and other sorts of knowledge often remains latent, he might say, in the state of reason that is potentially present in all individuals, and therefore cannot be called "innate" knowledge; but, for all that, such truths "carry their own evidence along with them" in every mind that is rationally awake. Even in the first book he appeals to what might be called common reason, which he calls "common sense," and which he thought would of common sense who asked, on the one side, or, on the other, want to give a reason, why 'tis impossible for the same thing to be and not to be. It carries its own light and evidence with it, and needs no other proof, he that understands the terms assents to it for its own sake, or else nothing will ever be able to prevail with him to do it" (bk. i. chap. 24). The idea that Locke here presents to intellectuals of the 17th century expressed their meaning with enough of precision; if they had, Locke's first book would probably have taken a form more consistent with its true intention. It is really to be read as an energetic argumentative protest against anything in human knowledge being supposed to be independent of rational criticism. Locke believed that in attacking innate principles he was really substituting conscious self-evidence and rational demonstration instead of blind repose on authority, and was thus, as he says himself, not "pulling up the foundations of knowledge," but "laying these foundations sure." Truth is to be found in "the constitution of things themselves," that is, by actual rational insight on the part of each individual. But when men heard of "some general propositions that could not be doubted as soon as understood," it was a short and easy way to conclude that such propositions are "innate," and that a personal perception of their truth and self-evidence is unnecessary. This language once received, "it ceased the lazy from the pains of search,

and stopped the inquiry of the doubtful concerning all that was once styled innate." Dogmas became protected against rational criticism. "It was no small advantage to those who affected to be masters and teachers to make thus the principle of principles—that principles must not be questioned." The mere assumption that we are "innate" was enough "to take men off the use of their own reason and judgment, and to put them upon believing and taking upon trust without further examination . . . Nor is it a small power it gives a man over another to have the authority to make a man swallow that for an innate principle which may serve his purpose who teaches them" (bk. i. chap. 4, § 24). Locke's examination of the way in which the rational consciousness of self-evident truths is actually reached refers them to "the bang of things themselves daily considered, and to the application of those faculties that are fitted to receive and judge of them when duly employed." Thus the reasoning which runs through the first book is a return to a more general and therefore more philosophical way, to that defence of individual rational insight against blind dependence on authority which was offered in the *Letters on Toleration*.

The Second Book opens with the suggestion of a general proposition regarding the genesis and constitution of ideas or thoughts, which it does after a laboured endeavour to verify it. This hypothetical proposition is that all human thoughts, even the most complex and abstract, are due to "experience." If so, the significance of all abstract words, and the objective truth of all individual thoughts, must be tested by the elements of which "experience" consists, and cannot in any instance claim protection against this test.

The important point is what "experience" consists of. Locke says that it all comes either from external sources or from the mind itself; and he promises to show that even our most abstract thoughts, which seem to reach to infinity, may be traced to one or other of these constitutents. In the first words, our most "complex ideas" are all made up of "simple ideas," either from without or from the mind; they are due to phenomena of which we are percipient in the five senses, or else due to reflexion upon "the operations of mind." The "reflection" of this position, in the central chapters of the second book, is to the effect that even those thoughts which are "most abstract, how remote soever they may seem from sense, or from any operations of our minds, are yet only such as the understanding fashions to itself by repeating and joining together ideas that it had either from objects of senses, or from its own operations about objects of sense; and that even large and even complex ideas, taken from one or other of the two sources (bk. ii. chap. 12, § 8). For this purpose our thoughts of space, time, infinity, power, substance, personal identity, causality, and several others which "seem most remote from the supposed original," are examined one after another, in the "historical plain method," and their complicated constitution is revealed to be made up of (a) perceptions of things through the five senses, or into (b) perceptions of operations of our own minds.

The source of experience which depends upon the five senses Locke calls *sensation*; the other, through which mind is reflectively aware of its own operations, he calls *reflection*. This last, "though it be not sense, as having nothing to do with external objects," is yet, he says, "very like it, and might properly enough be called internal sense." The suggestion that "sense" might designate both the springs of experience is misleading, when we find in the sequel how much Locke tacitly credits "reflection" with,—in the way of rational tendencies and intellectual obligations; it may be objected, to on grounds like those on which the somewhat analogous employment by Reid and others of the "common sense" for common reason has been condemned. They both mean to say that we may call that "sense" in which reason at once carries the light of its own evidence, and does not even admit of external proof. Reason in its own evidence is then supposed to be what is so popularly assumed to be. The elasticity of Locke's language in explaining his thesis makes the most opposite interpretations of the *Essay* possible, and all we can do is to compare one part with another, and in doubtful cases to give him the benefit of the doubt. His reluctance in the use of words is unfortunate. It was partly caused by a determination to avoid rigid technicalities, and partly by "Sensation" for instance is, in one definition, confined to "impressions or motions made in some part of the body which produce perceptions in the understanding" (bk. ii. 1, § 28); yet, when treated as one of the two springs of experience, it is made equivalent to what philosophers now call *self-perception*, while "reflection" turns out to be another name for *self-consciousness*. Accordingly, although the second book is professedly limited to the examination of our ideas or thoughts only, it by implication makes the (provisional) assumption that the "ideas" of which we are conscious in "sense" are at the same time to be regarded as "qualities" of sensible things which in some sort or other are perceived by us. It is also that the successive "operations" presented in "reflection" are those of an individual mind, presumed to exist somehow independently of them. Locke thus starts as a *common sense* perceptualist, and likewise relieves himself of the difficulty of having at the outset to show how the data abstracted by each sense are united in real

things and persons. In order to make his theory work, he begins by assuming a *Hypothetical duality* beneath phenomena—some phenomena referable to external things, others referable to the conscious self,—and in fact confesses that this dual experience is the ultimate fact, the denial of which would make it impossible to speak about the growth and constitution of our thoughts.

In the early chapters of the second book, the "simple" thoughts into which he promises to resolve all possible "complex" ones are arranged in classes. Some of them, he reports, are constituted "by one sense only," as colours by sight, or heat, cold, and solidity by touch, others "by more senses than one," as space or extension and motion, which are perceptible both by the eyes and by touch, or a third class are got from reflexion only, when "the mind turns its view inward upon itself," and by this means we get our ideas of perception or thinking itself, and also of willing, as well as the "modes of these two," such as remembrance, discerning, reasoning, knowledge, faith, &c.; lastly, there are simple ideas which we have both from sensation or reflexion. For instance, our thoughts of bodily and mental pleasures and pains, as well as thoughts of existence, unity, power, and succession. Such, according to Locke, are the elements of the simplest human thoughts. While the mind is becoming gradually stored with simple ideas like these (which are, however, somehow complex for us, when we "are conscious of them"), we find a growing power to elaborate them for ourselves at pleasure in an almost infinite variety; we are in fact obliged to do this in our tentative endeavours inductively to bring the thoughts of our individual minds into harmony with the actual complexity of thought that is presumed to us in the order of nature. "But it is not in the power of the most exalted wit or enlarged understanding to invent or frame any new simple idea not taken in in one or other of these two ways,—in proof of which Locke would have any one try to fancy any taste which had never affected his palate, or frame the thought of a scent he had never smelt, and when he can do this he is ready to concede that a born blind man has ideas of colours, and a born deaf man notions of sounds."

The contrast and correlation of these two fountains of individual experience is suggested in the eighth chapter of this book, on the "qualities of matter, in which we are introduced to a noteworthy vein of speculation running through the *Essay*. A chapter on "qualities of things" looks like an interpolation in an examination of our individual thoughts; its relevancy appears when we remember Locke's previous hypotheses, according to which simple ideas of matter may also be viewed as qualities of things. Now, our original sense-thoughts are, we find, partly revelations of *external things themselves* in their essential externality or extension, and partly sensations, boundless in their variety, which are somehow raised in us through contact with the things. Locke calls the former primary qualities, the latter secondary qualities of matter, and the others its secondary or derived qualities. The primary, which involve mathematical relations, and might be called quantities rather than qualities, are inseparable from matter as matter, and somehow exactly correspond, he reports, to the thoughts we have of them. On the other hand, there is nothing in the mathematical relations of space-occupied body which in the least resembles our ideas or thoughts of the secondary qualities; they are qualities of bodies at all, rather than sensations in us, only in so far as our different secondary sensations somehow correlate with (unknown) sizes, shapes, and motions of the primary particles, with which they are thus in an established harmony. Therefore, if there were no sentient and intelligent beings in existence, the secondary qualities would cease to exist,—except perhaps as unknown modes of the primary, or, if not, as "something still more obscure." On the other hand, "solidity, extension, figure, and motion, and rest were really in the world as they the moment there were any sensible being to perceive them or not" (bk. ii. chap. 21, § 2). The outcome of what Locke teaches about the mutual relations of matter (*a*) known as occupied-space, and (*b*) known in and through the sensations caused by secondary or relative qualities, is that it is something capable of being expressed at once in terms of mathematical quantity or extension, and also in terms of sense-consciousness. A further step would have led to the conception of the correlative dependence of all the so-called qualities of bodies upon "the bulk, figure, number, situation, and motions of the solid parts of which they consist," and which, as we think of them, whether we think of them as they are perceived. The true conception of an individual body would then be a conception of the actual mathematical relations of the atoms of which it consists, regarded as the established "occasions" of the sensations of colour, resistance, sound, taste, or smell which we refer to it as qualities; and also of the fact that it occasions in the minds of those whose individual bodies consist, which are followed by their operating on sentient beings differently from what they did before, as when the sun melts wax. But Locke only suggests in a hesitating way that the powers of bodies which are manifested in sensible changes may be conditioned by unknown changes in the mathematical relations of their inextensible atoms, or, if not thus dependent upon them, conditioned by

"something yet more remote from our comprehension." For, not knowing what size, figure, and texture of particles are which depend and from which result those qualities which make our complex ideas, for example, of gold, "it is impossible we should know what other qualities result from, or are incompatible with, the same constitution of the insensible parts of gold, and so consequently must always consent with that complex idea we have of it, or else be inconsistent with it."

Some of the most remarkable chapters in the second book are those which relate to the verification of its initial proposition. They carry us towards the metaphysical mystiques which so attract mediæval minds. The hypothesis that our most complex thoughts are all resolvable into "experience" is tested in those chapters by the *modes or modifications, and substantiations, and relations* which, in various degrees of complexity, we find ourselves somehow obliged to make the simple phenomenal thoughts of sense and reflexion undergo. Such, for instance, are the thoughts of finite quantity in space and time and number, in which Locke reports that we find ourselves mentally impelled towards immensity, eternity, and the unmeasurable, that is to say, towards Infinity, which transcends quantity; the complex thought of Substance, towards which he reports that we find ourselves impelled in another of the "operations of our minds," when the simple phenomena of the senses have to be regarded as powers or qualities of "something"; the thought of the identity of individuals, involved in the apparently inconsistent ideas of their constant phenomenal changes, and, above all, the mental tendency we find we somehow have to suppose what we call "Cause" whenever we observe a change. Let us see how Locke deals with these crucial instances.

He dwells much on our uses of Space, Succession, and Number. The first he says begins to appear when we use our senses of sight and touch, the second he finds "suggested" by all the phenomena of sense, but still more by "what passes in our minds"; the third "suggested by every object of our senses and every thought of our minds, by everything that either doth exist or can be imagined." The modifications of which these three sorts of simple ideas are susceptible he reports to be "inexhaustible and truly infinite," extension alone affording a boundless field to the mathematician. In his own nearest practical way, he finds many curious analogies between space and time. Neither is limited by the world of individual things. We can imagine space without bodies, but we cannot perceive or imagine bodies without space. Places and periods are all relative to objects and events, but both space and time are absolute in their nature. Time is finite in all directions, but while time has only one dimension. All things exist in the same present time, while no two things occupy the same space. The parts of time cannot be thought to occur; the parts of space cannot be thought to succeed one another. Whether the thought of unoccupied space is the thought of a substance or of an attribute Locke professes that he cannot tell, at least till they that ask show him "a clear distinct idea of substance."—"But the real mystery which he has to report of these thoughts of space and time is that "something in the mind" hinders us from imagining any limit to either. We find ourselves, when we try, obliged to lose our positive thought of space in the negative thought of immensity, and our positive thought of time in the negative thought of eternity. We have never seen, and we cannot mentally imagine, an object whose extent is boundless. Yet we find when we reflect that there is an "operation of the mind" which somehow forces us to think that space and time have no limits. "I would fan meet with that thinking man that can in his thoughts set any bounds to space more than he can to duration" (§ 21). Thus Locke by implication acknowledges something added by the mind to the originally presented simple ideas of extension and succession, though he explains that what is added is not positively imaginable. When we reflect on our thoughts of immensity and eternity, we find them to be thoughts, yet negations of all imaginable thought; and that whether we proceed by addition or by division. He characteristically accepts the fact; he does not inquire why mind should find itself thus obliged to add without limit, and to divide without limit. He simply reports that immensity and eternity are inevitable negative ideas, and that every endeavour to transform them into positive or imaginable ones only issues in the contradictory attempt to represent as a bounded quantity what is really infinite or beyond quantity. The idea of the infinite, or unmeasurable in extent and in succession, has so far, he finds, "something that is receivable into the simple positive ideas of space and time." For, when we try to think of the infinite in space or duration, we at first usually make some very large idea (imaginable in itself, though by men unmeasurable, or perhaps of millions of miles, or of days, or years, or we multiply millions of millions of times. All that we thus attain in our thoughts is positive (i.e., imaginable in its nature, although not imaginable by a human mind). But at the end of this we are as far from the infinite reality as we were at the beginning, so that what lies beyond the imaginable idea *remains* the infinite *He* "in obscurity and has the indeterminate confusion of a negative idea,"—inseparable and incomprehensible.

Locke, with all his aversion to what is unrepresentable in forms of existence and succession, is too faithful to rational facts to overlook these mysterious elements of our rational experience. His integrity is also illustrated in his acknowledgment of the unimaginable, and in this sense inconceivable, in our thought of Substance. He tries to phenomenalize it, but he finds that it cannot be phenomenalized, and yet that we cannot dispense with it. An unsubstantiated succession of phenomena, without a centre of unity to which they are referable, is unintelligible, we could not have a language consisting only of adjectives. Locke had an obscure apprehension of this intellectual obligation as a fact of rational consciousness. According to his reports, "the operations of the mind" oblige us to suppose something beyond phenomena, to which as qualities phenomena must belong; but he was honestly perplexed by the "confused negative" thought of this "something," which was all that he could reach, and of which he says we "neither have nor can have any positive idea either by sensation or reflection." The word substance thus means "only an uncertain supposition of we know not what" (i. 4, § 18). All attempt to realize it is like the attempt to reduce immensity or eternity, and we are involved in an endless—inevitable yet incomprehensible—regress. If one were to ask what the substance is in which the colours and that taste and smelling "where," and was told that they belong to the solid and extended parts, or primary qualities, of the thing, he must again ask what their substance is, and so on for ever. "It would be in a difficulty like the Indian, who, after saying that the word rested on an elephant, and the elephant on a broad-backed tortoise, could only suppose the tortoise to rest on 'something, I know not what.'" We must fail, in short, when we try earlier to phenomenalize our thought of substance or to dispense with it. He finds that our only positive complex ideas of substances are these in which we imagine an aggregate of attributes; it is only thus that we can rise to any positive thought even of God, in "the power we have of enlarging indefinitely some of the ideas we receive from sensation and reflection" (ii. 28, § 83). Why we must be in this strange mental predicament with regard to our thought of substance, Locke characteristically did not inquire. He reported the fact in his own case, and in the case of others.

He struggled bravely to be faithful to facts in his report of the no unlike mental predicament in which we find ourselves when reflection awakens in us the conviction of our own individuality and continued personal sameness. The paradoxes of expression in which he gets involved in the effort to express personal identity are evidence of this. He makes the thought of our actual individual personality, given in our consciousness of something external to self, and above all in our moral experience of responsible agency, with the negative thought of the transcendental relation of substance, which, we try to phenomenalize, to be the source of an uncertain supposition of we know not what.

But we must pass on to his report about our thoughts of Causality and Power, especially as his theory of real knowledge in the fourth book is very much an application of the principle of causality. The intellectual demand for the cause of an event is what we find we cannot help having, and yet it is a demand for what in the end we cannot grasp in a phenomenal representation. The causal thought in the form of power very much perplexed Locke, in his famous chapter on that idea (21); the perplexity is not so obvious in the sections on "cause and effect." In another chapter (26), where he considers only the circumstances in which this relational thought arises, he does not help having, and yet it is a demand for what in the end we cannot grasp in a phenomenal representation. The causal thought in the form of power very much perplexed Locke, in his famous chapter on that idea (21); the perplexity is not so obvious in the sections on "cause and effect."

Locke traces the thought of "cause and effect" back to our "constant observation" that "qualities and finite substances begin to exist, and receive their existence" from other beings which produce them. Soaring, for instance, flat, in the substance in which we call water, is constantly produced by the application of a certain degree of heat, we somehow come to think of heat as the cause and fluidity as the effect. This is to report what happens in our minds when we observe a particular example of that causal connexion which gives intelligibility to successive phenomena, converging into the concentrated system which we call the universe. Through calculated observations we, in this way, learn that *this* is the cause of *that*, and that *such as this* is the cause of *such as that*. But Locke's words in the 26th chapter do not explain the rational need for this causal expectation. Anything, as far as we can know, is constantly produced by the cause of anything; no finite number of instances can be "observed" sequence—in the strict meaning of the term—"observation"—can guarantee its universality. Elsewhere, indeed, he adds to this meagre account the important statement that "Our clearest idea of power is got through our consciousness of our own voluntary agency, and therefore through reflection" (ch. 21). Really phenomena he there reports to be incapable of presenting originary agency, this being an idea which cannot be phenomenalized in external sense. In changes among bodies we observe no origination, but only phenomenal order—significant and therefore interpretable phenomena. The thought of the "production" of actions is connected with what we are conscious of when we exert volition. Locke here approaches the view of power afterwards taken by

Berkeley, which was the constructive principle of Berkeleyan philosophy. But neither Locke nor Berkeley explains the transformation of our moral consciousness of ourselves, as free or originary, and therefore, to this extent, responsible agents, into the universal rational principle, on which both proceed in explaining our knowledge of the real existence of God and of the sensible world. Locke's language sometimes suggests that the transformation is made through an induction that is either instinctive or produced by custom. Now, not to say that every inductive generalization presupposes causal connexion, the particular fact that this, that, or the other person, through his moral experience, finds *himself* a free cause, does not, consistently with inductive rules, warrant the *general* conclusion that the phenomenal changes of the universe must all be referred to power like our own personal power. That we are somehow obliged to think a cause or phenomenal cause, and ultimately an uncaused or free agent, of every change—that we are obliged to view changes as events or issues from adequate productive causes into which they may be referred—is vaguely accepted in the *Essay* as a fact of rational consciousness; but no explanation is given of its origin, only of the circumstances in which it arises in the individual mind. The suppositive reason also asks why the individual mind is obliged to think back all changes into sufficient causes of which they are the issues, and why each set of antecedent phenomena, into which we thus refund new phenomena, themselves occasion a fresh intellectual demand for a preceding cause, while, after all, the mind is still left dissatisfied until it rests in a truly originary or unconditional cause. And yet if the intellectual need for a phenomenal cause were withdrawn there could be no rationality in, and therefore no reasoning possible about, Nature, for all the physical government of the universe depends upon it; and again, if uncaused or unconditional power were withdrawn there could be no moral responsibility or moral government. This sort of *reductio ad absurdum* of every merely empirical analysis of the causal thought into what is strictly observable was foreign to Locke. His aversion from mysticism may have made him pass slightly over the mystery of an experience that like ours is conditioned by relations of place, which lead to the unimaginable thought of Infinity, of succession, which lead to the unimaginable thought of Eternity, and of change, which lead to the unimaginable thoughts of Substance and Power.

Locke's book about our individual ideas or thoughts leads naturally to his Third Book, which is especially about those of them which are powers and abstract; and more especially regarding the latter. It is here that he describes "abstract ideas;" here also he illustrates the confusion apt to be produced in our thoughts by the imperfections of language.

But we must pass on to the Fourth Book, about knowledge, which we described in the *Essay*. It is, as we perceived, a discernment of relations among our thoughts, a knowledge of their government, and therefore a knowledge of their nature. In his books about our "ideas" he had dealt with "simple apprehensions;" here he is concerned with "judgments" and "reasonings," and largely with judgments and reasonings about matters of fact. At the end of the long and patient research among our mere thoughts or simple apprehensions, he supposes his reader apt to complain that he has been "all this while only building a castle in the air," and to ask what the purpose is of all this stir about our thoughts, or our knowledge either, if we are not thereby carried beyond our own individual thoughts, and must accordingly regard our faculties as the universe. "If it be true that knowledge lies only in the agreement or disagreement of our own ideas, the visions of an enthusiast and the reasonings of a sober man will be equally certain. It is no matter how things themselves are" (iv. 4, § 1). This is the keynote of the fourth book. It does not, however, carry him into an analysis of the nature of knowledge, but he regards as knowledge, as it would carry a transcendentalist of the 19th century, or even an associative philosopher. Transcendental analysis is too remote from human affairs to interest Locke. Hence, moreover, had not yet shown the difficulties which sceptical ingenuity could suggest against those facts of rational consciousness which Locke accepted without analysis.

The sceptic who doubted the very constitution of reason and experience, because it could not be supported by external proof, was less in his view than minds blindly resting on authority or on irrational instincts. Universal scepticism like Hume's he would at any rate probably have regarded as a frivolous amusement, into which no human mind could permanently subside, and therefore unworthy of the serious attention of a wise man. What he wanted was to awaken a conscious conviction of principles apt to be dormant in the individual, but to which he believed a response must be given when reflection was called forth. He was anxious to show how these principles might be developed into a reasoned system of speculative philosophy. "Where we perceive the agreement or disagreement of any of our ideas there is *certain* knowledge; and wherever we are sure these ideas agree with the reality of things, there is *certain* real knowledge" (ch. 4, § 18). He is anxious throughout to show that a great deal of commonly supposed real

knowledge is not entitled to be called "knowledge," and that it is merely presumption more or less probable. Instead of the immediate or the demonstrable insight, which alone is what he intends by knowledge, it is only "assent," "opinion," "probability."

Locke's report about human knowledge and the narrow extent of it is contained in the first thirteen chapters of the fourth book. The remainder of the book is concerned for the most part with what his found when he examined instances of "assent" or reasonable presumption, so liable to error, but on which human life really turns, as he and Butler are fond of reminding all transcendentalists. He takes for granted that "all the knowledge we have or are capable of" must be discernment of one or other of four sorts of agreement or disagreement among our thoughts themselves, or between our individual thoughts and the reality that is independent of them. All that can be conceivably known must be either (a) relations of identity and difference in what we are conscious of, that, for instance, "blue is not yellow"; or (b) that thought being mathematically related to that, as, for instance, that "two triangles upon equal bases between two parallels must be equal"; or (c) that one quality does or does not coexist with another in the same substance, as that "iron is susceptible of magnetical impressions"; or (d) that a thought has a real objective existence, independent of our individual mind, as that "God exists," or the "earth exists." What would now be called merely analytical knowledge exemplifies the first sort, mathematical Locke would add moral knowledge represents the second; physical and natural science, if this can become knowledge proper at all, would come under the third head, metaphysical knowledge forms the fourth. The third and several following chapters of this concluding book of the *Essay* are really an inquiry, under these four heads, how far knowledge is possible for man in mathematics, and in morality; about nature of natural phenomena in relations of coexistence and succession; and about the hyperphenomenal reality of our own existence, the existence of God, and the existence of matter.

Locke found a difference among the examples of what "knowledge" is that was offered in his natural experience. In some instances the known reality was at once evident, as when he judged that a circle was not a triangle, or three more than two and equal to one and two. In other cases the known relation was perceived only through the medium of something else, as in a mathematical conclusion, in which each step is taken by a rational intuition. The former is rational knowledge, the latter is rationally demonstrated knowledge. In strictness all knowledge or rational certainty, he would have it, is in one or other of these two kinds. There is, however, a third sort of certainty which rather puzzled him. He found that "our perceptions of the particular existence of finite beings without doubt, and the highest probability, although they are not examples of rational necessity. There is nothing contradictory to reason in the supposition that our sense-perceptions are illusory, although we are, in fact, incapable of doubting their reality. We find ourselves 'inwardly conscious of a different sort of perception,' when we look on the sun by day and only imagine the sun at night. This, which is Locke's third sort of knowledge, might be called sense-perception. This difficulty that a "sense-perception" only of the present moment, divorced from the past and the future, can be other than "blind," or irrational, does not occur to him.

Locke next inquired to what extent a human knowledge—or the way either of intuitive or demonstrative rationality, or of sense perception—is possible in regard to each of the four (already mentioned) sorts of knowable relation in which must be contained all knowledge we can be supposed capable of. Of our knowledge must of course be confined within our "ideas"; for it is self-evident that we cannot have knowledge of a thing if consciousness is dormant. But there is only one of the four sorts of knowable relation in regard to which our knowledge is coextensive with our thoughts. The only knowable relation which he finds to be coextensive with his thoughts is that of "identity and diversity"; he cannot be conscious of all without distinguishing, and every distinction implies negation. The second sort of knowable relation—purely rational constatement among our thoughts—is intuitively and also demonstrably discernible in thoughts about quantities, in forms of space, time, and number; it is through this channel that the mathematical sciences are constructed. Morality too, Locke thinks, as well as quantity, is capable of being thus rationalized. "Where there is no property there is no injustice," he offers as an example of a proposition "as certain as any demonstration in Euclid." Only we are more apt to be biased, and thus to have reason withdrawn from us, in dealing with problems of morality than in dealing with those of mathematics. Mankind might in consequence, in questions of morals, "with Egyptian darkness expect Egyptian bondage, were not the candle of the Lord set up by himself in their minds" (ch. 4, § 20). It is not easy to say whether the mathematical sciences which Locke finds thus demonstrable would be, as understood by him, sciences of what Kantists call analytical judgments founded on arbitrary definitions, or sciences consisting of synthetical judgments *a priori*.

In turning from mathematical and moral relations to those of

coexistence and succession among phenomena,—Locke's third sort of knowable relation,—he finds the light of pure reason disappear, although the relations in question are those in which "the greatest and most important part of what we desire to know" consists. Of relations of this third kind, with which all the physical and natural sciences are concerned, he repeats that "our knowledge is very short, if indeed we have any at all," and are not wholly thrown on presumptions of greater or less probability, or even left in ignorance. According to the philosophy of this *Essay* "there can be no sciences of bodies." All physical and natural sciences depend on a knowledge of the relations between the secondary qualities and other powers of bodies on the one hand, and the primary or mathematical qualities of their atoms on the other, or else "on something yet more remote from our comprehension." Now, as a rational insight of these relations, either instantaneous or through demonstration, is beyond our reach, we must be satisfied with inductive presumptions, which the completest "verification" leaves, after all, only presumptions that more facts might prove to be unwarranted. Our inductive generalizations about particular things must always involve an element of possible error, or at least inadequacy, and therefore of probability only. The presumption is "sufficient for all other things, except Arbitrariness of connexion, and not rational necessity, require over the whole realm of physical government, with its relations of constant coexistence and succession; we only presume, as reasonably as we can, what its actually established laws are, and we can only presume that these laws are sustained in a steady and uniform government." The presumption is "sufficient for all other things, except Arbitrariness of connexion, and not rational necessity, require over the whole realm of physical government, with its relations of constant coexistence and succession; we only presume, as reasonably as we can, what its actually established laws are, and we can only presume that these laws are sustained in a steady and uniform government." The presumption is "sufficient for all other things, except Arbitrariness of connexion, and not rational necessity, require over the whole realm of physical government, with its relations of constant coexistence and succession; we only presume, as reasonably as we can, what its actually established laws are, and we can only presume that these laws are sustained in a steady and uniform government."

The amount of our knowledge under Locke's fourth category of knowable relations—those of real metaphysical or metaphenomenal existence—is reduced, in his report, to—(a) rational perception of our own individual existence as conscious persons, (b) the demonstrative rationality of the existence of God or Supreme Mind, and (c) sense-perception of the existence of particular objects—as long as, but only as long as, they are actually present in sense. That each individual person exists is manifested to himself in memory, and no certainty beyond that of each passing thought while it passes can be greater than this. "If I doubt that I exist, says Locke, after Descartes, 'that very doubt makes me perceive my own existence, and will not suffer me to doubt of that' (iv. § 8). The eternal existence of God or Supreme Reason is with Locke only another way of expressing the principle of causality and sufficient reason in its universality as manifested by our conviction that our own personal existence had a beginning. Each individual person knows that he now exists, and is convinced that he once had a beginning; with not less intuitive certainty of reason he knows that nothing can no more produce any new being than that it can be equal to it, or be right angles to it. The final conclusion is that there must be eternally "a most powerful and most knowing Being, in which, as the origin of all, must be contained all the perfections that can ever after exist," and out of which can come only what it has in itself, so that, as the adequate cause, it must involve matter. There is thus a rational assurance for Eternal Reason, or what we call God. He cautiously adds elsewhere, "Though I call the thinking faculty in me 'mind,' yet I cannot, because that name, equal it in any thing to that infinite and incomprehensible Being which, for want of right and distinct conceptions, is called 'mind' also, or the eternal mind."

Turning from the metaphysics of religion to the metaphysics of matter, nearly—but perhaps not quite—all that one can affirm or deny about things external to us is, according to Locke, not knowledge but only presumptive truth. We have on the whole as much knowledge of the real existence of anything other than our individual existence, that of Universal Reason, and that of particular objects of sense—while, but only while, they are present to our senses. "When I see an external object at a distance, a man for instance, I cannot but be satisfied of his existence while I am looking at him," (Locke might have said, "while he has a sense of me") "it is only his *visible* qualities that are perceived; for his other qualities are as little 'actual present sensations' as if he was out of the range of the senses altogether." But when the man leaves me alone, I cannot be certain that he still exists. There is no necessary connexion between his existence and my sense (when he was present to my sense of sight) and his existence now (when he is absent from all my senses); by a thousand ways he may have ceased to be. I have not that certainty of his continued existence which we call knowledge; though the great likelihood of it puts it past doubt. But this is but probability and not knowledge" (chap. II, § 9). Either a rationally intensive or a rationally demonstrative science of Nature is thus, according to Locke, impossible. A conception of the co-existences and successions of phenomena which form the external world being essentially the natural expression of the Universal Mind, we are therefore capable of being reasoned about by our individual minds, in our gradual scientific progress towards agreement between the objective thought in nature and our subjective thoughts, was too speculative and mystical for Locke. He prefers to urge the matter-of-fact consideration that all our interpretations

of nature can be only presumptive probabilities—not purely rational certainties. For into the vast regions of reality—beyond our immediate sense-perceptions, memory, and the demonstrably necessary causal connection with Universal Mind—no other presumed probability, grounded on faith, or else it is within that veil which equates what is behind it from reasonable belief as well as from knowledge. And he even fails to explain how anything at all above the world of sense can be “known” in a sense-perception that is restricted to the transitory “actual present sensation” of each moment. No past events and no future events can be known in the strict meaning of “knowledge.” It is unreasonable to demand a knowledge of nature that exceeds present and present-momentary experiences. For the rest, we can only gradually convert beliefs into certainties that are absolute for all practical purposes. Such is the outcome of the *Essay*.

We might expect to learn from Locke something as to the rationality of the probable presumptions by which, as supplementary to our limited knowledge of real existence, we pass beyond the narrow sphere within which that knowledge is confined, according to his report of it, and possess ourselves so far of the unperceived past, distant, and future, in our experimental reasoning. He does little to satisfy us here. The concluding chapters of the fourth book contain valuable advice for human beings, whose lives are passed in a world of probabilities and presumptions, for avoiding the consequent risks of error or misinterpretation in their reasonings about what they see,—with or without the help of syllogism, the function of which, is an organ of discovery, he criticizes in the seventeenth chapter. Nothing is done to connect “probable” interpretations of the contingent phenomena of existence with the rational relations involved in the knowable part of the constitution, with which the preceding chapters were occupied.

This subject was resumed by Hume, very much at the point where Locke left it. With a still bolder view of the possible extent of human knowledge than Locke's, Hume proposed as a subject “worthy of curiosity,” to inquire what is “the nature of that evidence which assures us of any real existence and matter of fact, beyond the present testimony of our senses and the records of our memory,” remarking that “his part of philosophy has been little cultivated—because the ancients and the moderns.” The result of the inquiry was his announcement that Custom and the associative tendencies are a sufficient practical explanation of the formation of our experience. All beyond each present transitory “impression” is connected with it, through “ideas,” by means of Custom and Association. Hume's solvent, in the form either of individual or of inherited associative tendency, has since been made the philosophical explanation of all human experience in the Empirical Philosophy to which his *Inquiry* conducted. As for Locke, the “association of ideas”—either in the individual or as inherited—was introduced in the first edition of the *Essay*. The short chapter on the subject—now found at the end of the second book—was introduced in the second edition, not as in any way philosophically explanatory either of the thoughts or of the knowledge and probable beliefs of men, but as the chief source of human prejudices—as a cause of human errors against which men, dependent largely on probable presumptions, need in an especial manner to be warned. This useful chapter was an afterthought added, regarding a tendency which Locke saw was apt to spoil the “quality” of our individual thoughts,—apt, if one may put it so, to make them inconsistent with the Universal Thought latent in nature, by which our personal thoughts about what the laws in nature are must be tested.

On the other hand, an analysis like Kant's of what is abstractly implied in knowledge is even more foreign to the design of Locke, and to the tone of his philosophy, than the attempts of 18th and 19th century associationists and evolutionists to account for knowledge as if it were a fact of physical science. To show, in the case of any self-evident conception or judgment, that without it knowledge could not exist at all, would be to show what Locke took for granted, for for all the purposes he had in view. His aim was to determine to what extent experience, presumed to be rationally constructed, could come within the individual consciousness of man. On the one hand, to analyse in the abstract the rational constitution of knowledge, into which he found that man is able only very partially to subdue the universe, or, on the other hand, to seek for the physical causes of its (partial) realization in the human individual, were neither of them inquiries properly included in his enterprise.

Locke's function was to present to the philosophical mind of the modern world, in his own “historical plain method,” the largest assortment ever made by any individual of the actual facts of sense consciousness and rational consciousness in man. The further investigation of these facts, in Germany on the Transcendental Method, in England and France on the Empirical Method, as well as by Butler and Reid, in Locke's own Common Sense Method—all under the stimulus of Hume's sceptical analysis—has employed philosophy since the *Essay on Human Understanding* collected materials for speculation.

Literature—The *Essay on the Understanding*, which was thus the philosophy of Locke's own life, and also of the century which followed, has passed through more editions than any similar book of ancient or modern times. Before the middle of the 18th century it had reached a sixteenth, and it has now passed through some forty editions, besides being translated into Latin, French, Dutch, German, and modern Greek, in various versions. There are also several abridgements, in which the attempt is made to convert some of its immovable repetitions. A considerable philosophical library might be formed out of the editions and commentaries which are left given in the two hundred and ninety years. In addition to those which appeared when Locke was alive, some of which are mentioned above, among the most important are Leibnitz's *Remarques sur l'Entendement Humain*—written about 1700 and published in 1766, in which each chapter of the *Essay* of Locke is examined in a corresponding chapter. Comte's *Revue Scientifique* Systeme de Locke, in his *Revue de la Philosophie au XVIIIe Siècle*—written about 1780 and published in Professor Gauthier's Introduction to the *Philosophical Works of Locke*, 1874. The letters on Education, on Education, on Education, and on Education, which have also gone through many editions, and have been translated into different languages. The first critical edition of Locke's *Works* was in 1714, in three folio volumes. The new edition is that by Bishop Leys, in four quavos, 1777. The one most commonly known is in ten volumes, 1812. The *Essay*, as well as the other treatises, would require revision and critical annotation.

The *Stages of Life* (*Stages of Life*, 1703) has been the basis of the memoirs of Locke printed in the successive editions of his *Works*, and contained in the biographical dictionaries. In 1880 a *Life of Locke* in two volumes, was published by his descendant Lord King. This adds a good deal to what was previously known, as Lord King was able to draw from the mass of correspondence, journals, and accompanying books of Locke in his possession in the same year Dr Thomas Foster published some interesting letters from Locke to Benjamin Furley. The most copious account of the details of Locke's life is contained in the two volumes by Mr Fox published in 1895, which are full of interesting and faithful research in the Shaftesbury Papers, Locke MSS in the British Museum, the Public Record Office, the Leibnitz, Clarendon, Ashmole, and Bodleian Libraries, and in the Remains of the History of Shaftesbury (O. P.).

LOCKHART, JOHN GIBSON (1794–1854), was born in the manse of Cambusnethan in Lanarkshire, where his father, Dr Lockhart, was minister. His mother was daughter of the Rev. John Gibson, minister of St. Catherine's, Edinburgh. In 1796 his father was transferred to Glasgow, where John Lockhart was reared and educated. He derived his rare abilities from his mother, and his first regular teaching from the High School of Glasgow. He appears to have been from the first distinguished as a clever, but by no means industrious boy. Like most clever boys he read everything that came in his way; and what he had once devoured he never forgot, for his memory was so retentive that, in after life, like Macaulay and Sir George Lewis, he seldom found it necessary to verify a passage for quotation. No livelier boy than John Lockhart ever lived; in or out of school his sense of fun and humour, expressed in joke, sarcasm, and pencil caricatures, was irresistible. At the same time, however merry and mischievous, he was a proud and reserved boy; and this was the side he mostly turned to the outer world as a man. The struggle between a very affectionate nature and a determination not to show his feelings, or perhaps an incapacity to give way to them, cost him dear. A younger brother and sister were carried off within a few days of each other. John appeared to bear the loss like a stoic, but he fell seriously ill, and had to be removed finally from the High School. On his recovery, though still under twelve years of age, he was entered at college, where he sketched the professor for the amusement of his companions, as he had sketched the masters before. When examination time came, he astonished all by a display of erudition, especially in Greek authors, of the acquisition of which he had given no signs; a Small exhibition, just vacant at Oxford, was accordingly offered to him and accepted.

Lockhart was not turned fourteen when he was entered at Balliol College, but he soon asserted his character and his powers. His fun and satire made him, on one popular and formidable, while beyond the regular studies of the place he acquired a great store of extra knowledge. He read French, Italian, German, and Spanish, was curious in classical and British antiquities, and well versed in heraldic and genealogical lore. Lockhart went up to the schools in the Easter term of 1813—not nineteen years of age—and, notwithstanding the most audacious employment of part of his time in caricaturing the examiners, he came out first in classics. The name of Henry Hart Milman, a subsequent friend through life, stood next his. For mathematics he never had the least inclination.

He now quitted Oxford, and before settling to the study of Scottish law, for which his father had designed him, he indulged a long cherished wish to visit Germany. His knowledge of German had introduced him to the great band of poets and scholars who had suddenly exalted the fame of German literature. Lockhart had no means to undertake the journey; but here his reputation came to his aid. A proposal to translate Frederick Schlegel's *Lectures on the Study of History* was accepted by Mr Blackwood, and the price of the labour paid before a line was written. Lockhart always spoke of this as a most generous act on "Ebony's" part, and his friendship with the liberal publisher lasted through life. He meanwhile paid his visit to Germany, was introduced to Goethe at Weimar, traversed France and the Netherlands, made careful observations on pictures and architecture, and returned to Edinburgh to study law by the time he was twenty-one. In 1816 he was called to the bar. But he had no friends among writers and attorneys, his brilliant powers of conversation did not comprise that of public speaking, and few, if any, briefs came in. His habits of observation, however, turned the time to a use afterwards exemplified in *Peter's Letters*.

Edinburgh was then the stronghold of the Whig party. The *Edinburgh Review* was their organ, and it was not till 1817 that the Scotch Tories found a national channel of assertion and defence—namely, in *Blackwood's Magazine*. This periodical held its way dully enough with its first numbers, when suddenly an outburst of wit and ridicule directed against the hitherto unchallenged writers of the Whig party, surpassing them in cleverness and equalling them in personalities, electrified the Edinburgh world. Wilson (Christopher North), Hogg (the Ettrick Shepherd), and Lockhart had joined the staff, and retaliation for long pent-up wrongs began. Lockhart's pen contributed scholarly papers on various subjects, including hearty criticism and eulogium on Coleridge, Wordsworth, and other victims of a *Review* which could find only scant praise even for Walter Scott. His translations also of the Spanish ballads appeared for the greater part in *Blackwood*. But his pen was more often dipped in caustic, dealing out attacks and recriminations which led to regrettable consequences. Meanwhile the gifted and handsome young man, for Lockhart's head was cast in the highest type of brilliant manly beauty, had attracted the notice of Walter Scott. They met first in 1818. The acquaintance soon ripened into friendship, and that friendship led to the union between Lockhart and Scott's eldest daughter, Sophia, in April 1820. For more than five years after his marriage Lockhart tasted the best form of domestic happiness. Winters spent in Edinburgh and summers at a cottage fitted up for them at pretty Chiefswood, near Abbotsford, gave the young couple the constant enjoyment of friendship, society, and even worldly distinction, added to the blessing of a perfect home. At Chiefswood Lockhart's two eldest children, John Hugh and Charlotte, were born; Walter, later, at Brighton.

Between 1818, when he joined the *Blackwood* staff, and 1825 Lockhart's pen was indefatigably at work. As early as 1819 *Peter's Letters to his Kinsfolk* appeared. Luke Goldsmith's *Chimes of the World*, these profess to give the impressions of a stranger in a new country. Dr Peter Morris, a Welsh physician, passes some time in Scotland, especially in Edinburgh, and describes the men and manners very freely in his relations at home. His descriptions of the chief notabilities of the day have a certain historical, almost antiquarian interest, though now the least interesting part of the work. What we enjoy most is the reflexion of a young and ardent mind dealing out opinions and estimates far beyond its years, the cor-

rectness of which time has singularly verified. The amount of reading to which crops out in every page is amazing; a perpetual play of allusions, quotations, and happy nicknames—for which Lockhart to his last days was famous—is given with a raciness of tone of which the reader might tire, but for the simple, vigorous English in which it is clad. A chapter on dandies is a *chef d'œuvre* in its way. That a work describing the appearance and idiosyncrasies of many living individuals should give offence was a matter of course. His description of the northern universities was not likely to please, while for the unsparing ridicule and ruthless quizzing heaped on the General Assembly—"men," he is supposed to have said, "of like passions with ourselves, but worse manners"—it would be strange indeed if the author had escaped with impunity.

Valerius, a Roman Story, followed next (1821). As *Valerius* was intended to illustrate the manners and customs of Rome in the time of Trajan, so *Reginald Dalton*, published in 1823, aimed at exhibiting the life of an undergraduate at Oxford as he had known it. Lockhart's strength did not lie in novel writing, and to those who read *Reginald Dalton* now, the digressions of the author are far more interesting than the adventures of the hero. But a plot of simpler construction and intense passion showed Lockhart's strength to greater advantage. *Adam Blair* (1822) is a tale of temptation, fall, and repentance, each fearful in its way, told with tremendous power, and as far removed from all that is morbid and false in sentiment as the author was himself. It gave great offence to the Scottish Church, for the erring man is a minister, and the scene is laid in a Scottish manse.

In 1826, on the death of Mr Gifford, the editorship of the *Quarterly Review* was offered to Lockhart, and accepted. He was singularly free in position, however far from idia. He was next heir to Milton Lockhart, the property of his unmarried half-brother, who eventually survived him; the legal profession to which he had been destined was virtually abandoned, and time had shown him that the party strife which prevailed in Edinburgh was demoralising to both sides. This last conviction did the most to reconcile him to the separation from all Scottish surroundings. His friends gave him a farewell dinner, when, labouring with strong feelings, and with his habitual dislike or incapacity to express them, he said, on returning thanks, "You all know that I am no speaker; had I been, there would have been no occasion for this parting."

The conduct of a great periodical like the *Quarterly Review* is the touchstone of a man's capacity, knowledge, and temper. Looking back to an editorship which lasted twenty-eight years, it must be admitted that Lockhart maintained a high position in all these respects. He contributed largely to the *Review* himself, his biographical articles being especially admirable. He also found time, being a very glutton in work, for many a paper in *Blackwood*; he wrote what remains the most charming of the biographies of Burns; and he undertook the superintendence of the series called *Murray's Family Library*, which he opened in 1829 with a *Life of Napoleon*. But his chief work was the *Life of Walter Scott*, a task at once of love and duty. Lockhart knew the great and good man as no one else did, and felt that, whatever the mistakes in judgment, no life from first to last could better afford complete revelation. There have not been wanting those in Scotland who have taxed him with ungenerous exposure of his subject, but to most healthy minds the impression conveyed by the biography was, and is, one of the most opposite kind—namely, that Lockhart has almost defiled Scott. The labour incurred was in so far one of love, inasmuch as the writer reaped

no part of its considerable proceeds, but resigned them absolutely for the benefit of Scott's creditors.

Lockhart's life in London was a long succession of constant work, of dignified social success, and of heavy bereavements. His eldest boy, the suffering "Hugh Littlejohn" of the *Tales of a Grandfather*, died in 1831. Sir Walter died in 1832, Anne Scott, the second daughter, who had come to live with the Lockharts in London, in 1833; Mrs Lockhart in 1837. The love for his children was for long the one bright element in his life. But the death in 1852, and, sadder still, the previous life, of his surviving son Walter, a fine youth, who had entered the army under unfortunate auspices, broke down all that remained of health and spirit in the father.

Failing health compelled Lockhart to resign the editorship of the *Quarterly Review* in 1853. He spent the next winter in Rome, but returned to England with no restoration of vital power. He was conveyed to Abbotsford, where, under the tender care of his daughter Mrs Hope Scott, and obeyed by the prattle of his granddaughter, now the possessor of Abbotsford, he lingered till his death, November 25, 1854. He was buried in Dryburgh Abbey, at the feet of Walter Scott. (E. E.)

LOCKPORT, capital of Niagara county, New York, about 21 miles east of Niagara Falls, at the point where the New York Central Railroad crosses the Erie canal. It takes its name from the locks (ten in number) by which the canal is lowered 66 feet from the level of Lake Erie to that of the Genesee river, and its prosperity as a manufacturing centre is due to the water-power. The surrounding country is a rich agricultural district, and in the vicinity are extensive limestones and sandstone quarries. Flour-mills are prominent among the industrial establishments, there are also numerous saw-mills, cotton and woollen factories, foundries, &c. Lockport was made a city in 1835. The population in 1870 was 12,426; in 1880, 13,522. The buildings in the business part of the city are generally heated by steam on the Holly distributing system, which originated in Lockport, as did the celebrated Holly water-works system.

LOCLE, Le, a large town-like village of Switzerland, in the canton of Neuchâtel, 10 miles W.N.W. from Neuchâtel. Along with La Chaux de Fonds, 5 miles north-east, it is the seat of the most extensive watch-making industry in the world; and it also carries on the domestic manufacture of lace. The valley in which Le Locle is situated used to be subject to inundation, but in 1802-6 a tunnel was constructed by which the surplus waters of the Bied discharge into the Doubs. About a mile to the west of the town the stream plunges into a deep chasm, and on the almost vertical face of the rock are what are usually called the subterranean mills of Cal des Roches, situated one above the other, to turn the water-power to account. The population of the commune was 10,464 in 1880.

LOCRI, a people of Greece who are found in two different districts, on the Ægean coast opposite Eubœa and on the Corinthian Gulf between Phœcis and Ætolia. The former are divided into the northern Locri Epizephyrîi, so called from Mount Cnemis, and the southern Locri Opuntii, whose chief town was Opus; but the name Opuntii is applied to the whole district by Thucydides, Herodotus, &c. Homer knows no distinction of tribes among the Locri. They were considered by Aristotle to be a Lelegian tribe; but they became Hellenized at an early time, and rank in Homer along with the other Greek tribes before Troy. Their national hero is Ajax Oileus, who often appears on coins. The Locri Ozolæ on the Corinthian Gulf were a rude and barbarous race who make no appearance in Greek history till the Peloponnesian War. It is said that they separated from the eastern Locri four genera-

tions before the Trojan war, but Homer does not mention them. The most probable view is that the Locri were once a single race spread from sea to sea, that subsequent immigrations forced them into two separate districts, and that the eastern Locri advanced with the growth of civilization, while the remote Ozolæ remained ignorant and barbarous.

A colony of Locrians, probably Opuntians, though Strabo expressly calls them Ozolæ, settled at the south-west extremity of Italy about the end of the 8th century B.C. They are often called Locri Epizephyrîi from the promontory Zephyrion 15 miles south of the city. The earliest and most famous event recorded in the history of the Italian Locri is the legislation of Zaleucus about the middle of the 8th century B.C. The Locri boasted that Zaleucus was the first of the Greeks to promulgate a written code of laws. A body of laws under his name existed in the city throughout the historical period, but the name of Zaleucus is almost as much surrounded with legend as that of Lycurgus. The Locrians are said to have defeated the people of Croton in a great battle at the Sagras, perhaps some time in the 6th century B.C., and in this flourishing period they founded colonies along the south coast of the peninsula. Their nearest neighbour was Rhegium, and the continual wars that raged between the two cities often drew other states into their quarrels. They sent ships to aid Sparta in the Lacedæmonian war. They were allied with the elder Dionysus of Syracuse, who gave them great accessions of territory (389-88 B.C.); the younger Dionysius ruled them as tyrant (365 B.C.). They admitted a Roman garrison before the expedition of Pyrrhus, but sided against the Romans with him and with Hannibal (216 B.C.). The town was finally captured by Scipio (205 B.C.) From this time we hear little of Locri. It seems still to have existed in the 6th century A.D., but in the Middle Ages it had disappeared entirely. The site and remains have been described by the Duc de Luynes (*Ann. Inst. Arch.*, n.). It possessed a famous temple of Proserpine. The town is celebrated by Pindar, *Ol. x.* and xi.

LOCUS, in Greek τόπος, a geometrical term, the invention of the notion of which is attributed to Plato. It occurs in such statements as these:—the locus of the points which are at the same distances from a fixed point, or of a point which moves so as to be always at the same distance from a fixed point, is a circle; conversely a circle is the locus of the points at the same distance from a fixed point, or of a point moving so as to be always at the same distance from a fixed point; and so in general a curve of any given kind is the locus of the points which satisfy, or of a point moving so as always to satisfy, a given condition. The theory of loci is thus identical with that of curves; and it is in fact in this very point of view that a curve is considered in the article CURVE; see that article, and also GEOMETRY (ANALYTICAL). It is only necessary to add that the notion of a locus is useful as regards determinate problems or theorems. Thus, to find the centre of the circle circumscribed about a given triangle ABC, we see that the circumscribed circle must pass through the two vertices A, B, and the locus of the centres of the circles which pass through these two points is the straight line at right angles to the side AB at its mid-point; similarly the circumscribed circle must pass through A, C, and the locus of the centres of the circles through these two points is the line at right angles to the side AC at its mid-point; thus we get the ordinary construction, and also the theorem that the lines at right angles to the sides, at their mid-points respectively, meet in a point. The notion of a locus applies, of course, not only to plane but also to solid geometry. Here the locus of the points satisfying a

single (or onefold) condition is a surface; the locusts of the points satisfying two conditions (or a twofold condition) is a curve in space, which is in general a twisted curve or curve of double curvature.

LOCUST. In its general acceptation this term is strictly applicable only to certain insects of the order *Orthoptera*, family *Acruidae* (see **INSECTS**), and it is advisable to reiterate that according to modern classification the family *Locustidae* is now viewed in a sense that does not admit of what are popularly termed "locusts" being included therein. We universally associate with the term the idea of a very destructive insect; therefore many orthopteran species that cannot be considered true locusts have had the term applied to them; in North America it has even embraced certain *Hemiptera-Homoptera*, belonging to the *Cicadidae*, and in some parts of England cockchafers are so designated. In a more narrow definition of the term we are wont to associate with the destructive propensities the attribute of migration, and it therefore becomes necessary that a true locust should be a migratory species of the family *Acruidae*. Moreover, the term has yet a slightly different significance as viewed from the Old or New World. In Europe by a locust is meant an insect of large size, the smaller allied species being ordinarily known as "grasshoppers," hence the notorious "Rocky Mountain locust" of North America is to Eastern ideas rather a grasshopper than a locust.

In Europe, and a greater part of the Old World, the best known migratory locust is that which is scientifically termed *Pachytelus migratorius*, to which is attached an allied (but apparently distinct) species known as *P. cinerascens*. Another locust found in Europe and neighbouring districts is *Caloptenus italicus*, and still another, *Acridium peregrinum*, has once or twice occurred in Europe (even in England in 1869), though it can only be considered a straggler, its home (even in a migratory sense) being more properly Africa and Asia. These practically include all the locusts of the Old World, though a migratory species of South Africa known as *Pachytelus pardalinus* (presumed to be distinct from *P. migratorius*) should be mentioned. The Rocky Mountain locust of North America is *Caloptenus spretus*, and in that continent there occurs an *Acridium* (*A. americanum*) so closely allied to *A. peregrinum* as to be scarcely distinct therefrom, though there it does not manifest migratory tendencies. In the West Indies and Central America the absolutely true *A. peregrinum* is also reported to occur.

As to general biology, a few words will suffice. The females excavate holes in the earth in which the eggs are deposited regularly arranged in a long cylindrical mass enveloped in a glutinous secretion. The young larvae hatch, and immediately commence their destructive career. As these insects are "hemimetabolic" (see **INSECTS**), there is no quiescent stage, they go on increasing rapidly in size, and as they approach the perfect state the rudiments of the wings begin to appear. Naturally in this stage they are incapable of flight, but their locomotive powers are nevertheless otherwise extensive, and their capacity for mischief very considerable, for their voracity is great. Once winged and perfect these powers become infinitely more disastrous, redoubled by the development of the migratory instinct. The laws regulating this instinct are not yet perfectly understood. Food and temperature have a great deal to do with it, and there is a tendency for the flights to take a particular direction, varied by the physical circumstances of the breeding districts. So likewise it is certain that each species has its area of constant location in which it always exists, and its area of extraordinary migration to the extremes of which it only occasionally extends. Perhaps the most feasible of the suggestions as to the causes

of the migratory impulse is that locusts naturally breed in dry sandy districts in which food is scarce, and are thus impelled to wander in order to procure the necessities of life; but against this it has been argued that swarms bred in a highly productive district in which they have temporarily settled will seek the barren home of their ancestors. Another ingenious suggestion is that migration is intimately connected with a dry condition of the atmosphere, urging them to move on until compelled to stop for food or procreative purposes. The distance particular swarms may travel depends upon a variety of circumstances, such as the strength of impulse, the quantity of food, and many other causes. Certain it is that 1000 miles may, in particular cases, be taken as a moderate estimate; probably it is often very much less, certainly sometimes very much more. As a rule the progress is only gradual, and this adds vastly to the devastating effects, which may be likened to those caused by a foreign army laying black-mail upon the inhabitants of an invaded country through which it is marching. When an extensive swarm temporarily settles in a district, all vegetation rapidly disappears, and then hunger urges them on another stage. Such is their voracity that it has been tolerably well ascertained that the large Old World species, although undoubtedly phytophagous, are often compelled by hunger to attack at least dry animal substances, and even cannibalism has been asserted as an outcome of the failure of all other kinds of food. The length of a single flight must depend upon circumstances. From certain individual peculiarities in the examples of *Acridium peregrinum* that were taken in England in 1869, it has been asserted that they must of necessity have come direct by sea from the west coast of Africa, and what is probably the same species has been seen in the Atlantic at least 1200 miles from land, in swarms completely covering the ship, and obscuring the air; thus, although it is no doubt usual for the swarms to rest during the night, it undoubtedly happens in certain cases that flight must be sustained for several days and nights together. The height at which swarms fly, when their horizontal course is not liable to be altered by mountains, has been very variously estimated at from 40 to 200 feet, or even in a particular case to 500 feet. A "dropping from the clouds" is a common expression used by observers when describing the apparition of a swarm. The extent of swarms, and the number of individuals in a swarm, are matters that must of necessity be purely speculative. That the sun may sometimes be utterly obscured, and the noise made by the rustling of the wings be deafening, is confirmed by a multitude of observers. We prefer to decline the attempt to grapple with so vast a subject,—not unnaturally so when one observer says of a particular swarm that, when driven out to sea and drowned, the dead bodies washed up formed a bank 50 miles long and 3 or 4 feet high.

No special periodicity appears to have governed these flights (which, it is necessary to state, happily do not occur to an alarming extent every year), still an American writer (Mr Thomas) makes the interesting remark that the interim between the years of superlatively extraordinary appearance is both in Europe and America "very nearly a multiple of 11."

In Europe the best known and ordinarily most destructive species is *Pachytelus migratorius* (fig. 1), and it is to it that the numerous records of devastations in Europe mainly refer, but it is probably not less destructive in many parts of Africa and Asia. Eastern Europe, and especially the plains of southern Russia, appear to be more especially liable to its attacks. That the east slopes of Central Asia are the home of this insect appears probable; still much on this point is enveloped in uncertainty. In any case the area of permanent distribution, according to Koppen (who published an elaborate memoir on the subject in 1871), is enormous, and that of occasional distribution is still greater. The former area extends from the parallel of 40° N. in Portugal, rising to 48° in France and Switzerland, and

passing into Russia at 55°, thence continuing across the tundra of Siberia, north of China to Japan, thence south to the Fijian Islands, to New Zealand, and North Australia, thence again to Mauritius and over all Africa to Madagasc. But Koppén remarks that the southern distribution is uncertain and obscure. Taking exceptional distillation, it is well known that it occasionally appears in the British Isles, and has in them apparently been noticed as far north as Edinburgh, so also does it occasionally appear in Scandinavia, and it has probably been seen up to 63° N in Finland. Looking at this vast area, it is easy to conceive that an element of uncertainty must always exist with regard to the exact determination of the species, and in Europe especially is this the case, because (as before stated) there exists an apparently distinct species, known as *P. caucasicus*, which Koppén does not take into

“locust.” In the Argentine Republic a (possibly) distinct species (*A. yuracaca*) is the migratory locust.

Culopterus dilatus (fig. 3) is a smaller insect, with a less extended area of migration, and, though from this cause its invasions are not so notable, still the destruction occasioned in the districts to which

FIG. 1.—*Pachytelus migratorius*. This and the other figures are all natural size.

account. This latter species is certainly the most common of the “locusts” occasionally found in the British Isles, and De Selys-Longchamps is of opinion that it breeds regularly in Belgium, whereas the true *P. migratorius* is only accidental in that country. In the case of this, as of all other locusts, it is impossible within the limits of this article to chronicle even the years of greatest abundance. That they are probably as destructive now as formerly appears within the bounds of belief. At any rate we read that only a year or two ago a detachment of Russian soldiers in Timocomania was held prisoners by the insects forty-eight hours, until the villagers killed them and carried them away for manure, locusts often being as difficult as if the men had been on ice.

Acyrtus peregrinus (fig. 2) can scarcely be considered even an accidental visitor to Europe, yet it has been seen in the south of Spain, and, most extraordinarily, in many examples spread over a large part of England in the year 1869. It is a larger insect than *P. migratorius*. No serious attempt to define the range of this species has yet been made, but there is every reason to believe that it is the most destructive locust throughout Africa and India and other parts of tropical Asia, and its ravages are not one whit less important than are those of *P. migratorius*. Presumably it is the species that, on more than one occasion, has been noticed in a vast swarm in the Atlantic, very far from land, and presumably also it occurs in the West Indies and some parts of Central America. But it has been already remarked that *A. americanus* of North America, although so closely allied as to be scarcely distinguishable, is said not to be migratory, and is therefore scarcely a true

FIG. 2.—*Acyrtus peregrinus*.

it hunted is often scarce less than that of its more terrible ally. It is essentially a species of the Mediterranean district, and especially of the European side of that sea, yet it is also found in North Africa, and appears to extend far into southern Russia.

FIG. 3.—*Culopterus dilatus*.

Culopterus apratus (fig. 4) is the “Rocky Mountain locust” or “hateful grasshopper” of the North American continent. Though a comparatively small insect, not so large as some of the grasshoppers of English fields, its destructiveness has procured for it within the last twenty years a notoriety scarcely equalled by that of any other. It is only recently that the persistent migration of American settlers westward extended into the home of this creature. Travellers and prospectors in these regions had previously spoken of enormous swarms of a destructive grasshopper as existing there, and no doubt these occasionally extended into regions already civilized, but the species was not recognized as distinct from some of its non-migratory congeners to which it is so closely allied as to require a practised entomological eye to separate it therefrom. As time drew on, the various “State entomologists” made it their special duty to report on the insect, and at length, in 1877, the matter had become so serious that Congress appointed a United

States Entomological Commission to investigate the subject, and report upon the best (if any) means of controlling the evil effects of the pest. The result, so far as published, consists of two enormous volumes, teeming with information, and taking up the whole subject of locusts both in America and the Old World. *C. spissus* has its home or permanent nest in the sand plains of the central region east of the Rocky Mountains, extending slightly into the southern portion of British North America, outside the

FIG. 4.—Rocky Mountain Locust (*Chortopterus spissus*). a, a, female in different positions, ovipositing; b, egg-pod extracted from ground, with the end broken open; c, a few eggs lying loose on the ground; d, a locust with the egg-pod partially removed; e, an egg-mass already in place, and one being placed; f, shows where such a mass has been covered up. (After Haly.)

is a wide fringe to which the term sub-permanent is applied, and this is again bounded by the limits of only occasional distribution, the whole occupying a large portion of the North American continent, but it is not known to have crossed the Rocky Mountains westward, or to have extended into the eastern States.

As to remedial or preventive measures tending to check the ravages of locusts, little unfortunately can be said, but anything that will apply to one species may be used with practically all. One point is certain, direct remedies must always be of small avail. Something can be done (as is now done in Cyprus) by offering a lure for all the egg-tubes collected, which is certainly the most direct manner of attacking them. Some little can be done by destroying the young larvae while yet in an unwinged condition, and by digging trenches in the line of march into which they can fall and be drowned or otherwise put an end to. Unfortunately little can be done with the winged hordes having the ingenuity instinct upon them, starvation, the outcome of their own work, probably here does much. It has been shown that with all migratory locusts the breeding places, or true homes, are comparatively barren districts (mostly elevated plateaus), hence the progress of civilization and colonization, with its concomitant necessity for converting those hitherto barren plains into areas of fertility, may (and probably will) gradually lessen the evil.

Locusts, like all other animals, have their natural enemies. Many birds greedily devour them, and it has many times been remarked that migratory swarms of the insects were closely followed by myriads of birds. Predatory insects of other orders also attack them, especially when they are in the unwinged condition. Moreover, like all other insects, they have still more deadly insect foes as parasites. Some attack the fully developed winged insect. But the greater part adopt the more cautious method of attacking the eggs.

To such belong certain beetles, chiefly of the family *Cynipidae*, and especially certain two-winged flies of the family *Bombilidae*. These latter, both in the Old and New World, must prevent vast quantities of eggs from producing larvae. Popular ignorance on this subject is yet great, and within a few months before this article was written it was exemplified in a remarkable manner by a suggestion from the Government officials of Cyprus that a certain parasite known to be destructive to the eggs in Asia Minor might be introduced into the island, a suggestion immediately followed by the discovery that what is probably the same parasite already existed there.

A flight of locusts would appear not to be always an unmitigated evil, even to man. The large Old World species form articles of food with certain semi-civilized and savage races, by whom they are considered as delicacies, or as part of ordinary diet, according to the race and the method of preparation.

(R. McL.)

LOCUST-TREE, *Ceratonia Siliqua*, L., the carob-tree, of the tribe *Cassieae* of the order *Leguminosae*, is the sole species, widely diffused spontaneously and by cultivation from Spain to the eastern Mediterranean regions, and from Egypt to Bornou in Central Africa (Hogg, Hooker's *Journal of Bot.*, 113), and imported to Hindustan (Graham, p. 254). It differs from all leguminous plants by the dilated disk to the calyx. It has no petals, and the flowers are polygamous or dioecious. The legume is compressed, often curved, indurated, and succulent, but with sweet pulpy divisions between the seeds, which, as in other genera of the *Cassieae*, are albuminous. The pods are eaten by men and animals, and in Sicily a spirit and a syrup are made from them. These husks being often used for swine are called swine's bread, and are probably referred to in the parable of the Prodigal Son. It is also called St John's bread, from a misunderstanding of Matt. iii. 4. The carob-tree was regarded by Spengel as the tree with which Moses sweetened the bitter waters of Marah (Exod. xv. 25), as the *Alcarab*, according to Avicenna (p. 205), has the property of sweetening salt and bitter waters. Gerard (*Herb.*, p. 1241) cultivated it in 1597; it having been introduced in 1570 (London's *Art.*, ii. 660). For various names, extent of distribution, historical references, &c., see Pickering's *Chron. Hist. of Fl.*, p. 141.

LODEVE, capital of an arrondissement of the department of Hérault, France, lies at an elevation of 674 feet, under a range of hills rising to 2790 feet, in a small valley where the Soulouff joins the Lez, a tributary of the Hérault, 34 miles east-north-east from Montpellier. A bridge over the Lez connects the town with the faubourg of Carnes on the left bank of the river, and two bridges over the Soulouff lead to the extensive ruins of the Château de Montbaur. There is railway communication with Agde by a line following the Hérault valley. The old cathedral of St Fulcran, founded by him in 920, was rebuilt in the 14th century and restored in the 16th; the cloister, dating from the 15th century, is ornate in style. In the picturesque environs of the town stands the well-preserved monastery of St Michel de Crammont, dating from the 12th century, it is now used as farm buildings. In the neighbourhood are three fine dolmens. Lodève is one of the most important industrial centres of the south of France, upwards of 7000 workmen being employed in the manufacture of woollens for army clothing, the aggregate horse-power of the factories is 1500. Wool is imported in large quantities from the neighbouring provinces, and from Morocco; the exports are cloth to Italy and the Levant, wine, brandy, chemicals, and wood. The population in 1876 was 10,528.

Latera existed prior to the invasion of the Romans, who for some time called it *Torvis Novus*. The inhabitants were converted to Christianity by St Flou, first bishop of the city, about 328. After passing successively into the hands of the Visigoths, the Franks, the Ostrogoths, the Arabs, and the Calabrians, it became in the 9th century a separate comitatus, and afterwards the domain of the bishops of Lodève. During the religious wars it suffered much, especially in 1578, when it was sacked. It ceased to be an episcopal see in 1789.

LODGE, THOMAS (c. 1556-1625), dramatist, novelist, pamphleteer, poet,—but not player,—was born about the year 1556 at West Ham, and was possibly the son of a namesake, shortly afterwards lord mayor of London. He was educated at Trinity College, Oxford, and then entered as a student at Lincoln's Inn, where, as in the other Inns of Court, a love of letters, and a crop of debts and difficulties, alike grew as matras of course. Thus already as a young man he preferred the looser ways of life and the lighter aspects of literature. When the pensive Stephen Gosson had (in 1579) published his *Schools of Abuse*, Lodge took up the glove in his *Defence of Poetry, Music, and Stage-*

plays (1679 or 1680), which shows some of the moderation as well as of the learning befitting a scholar and a gentleman. The publication was, however, prohibited, besides being answered by Gosson in his *Plays Confuted in Five Actions*, as by a man sure of his ground if not of his cause. Having fleshed his pen, Lodge displayed a strong inclination for continuing its use. In 1584 he published his *Atarum Against Unversers*, a pamphlet to which he no doubt gave the benefit of his personal experience, and in which he mentions the fate of his previous literary venture. Soon after this his years of wandering seem to have begun. It is clear that their primary cause lay in the straits to which he had been reduced, or had reduced himself; that he ever took so bold a leap into disreputableness as to become an actor is improbable in itself, and the assertion which has been made to that effect has been shown to rest on something less satisfactory than conjecture. Lodge joined Captain Clarke in his raid upon Terceira and the Canaries, and seems, in 1591, to have made another similar voyage with Cavendish. During the former expedition, he, to beguile the tedium of his voyage, composed his prose tale of *Rosaguide, Euphans' Golden Leguise*, which, published in 1590, afterwards suggested the story of *As You Like It*. The novel, which in its turn owes some, though no very considerable, debt to the *Tale of Gamelyn*, is a pleasing example of the Euphuistic manner, but proves how slight an advance an individual author of secondary rank is able to effect in a branch of composition of which the genius of his age has not taken hold. In the year before (1589) Lodge had already given to the world a volume of poems, including the delectable *Scyllas Metamorphosis*. One would gladly resign this and much else of Lodge's engorged verse, together with some of his perfumed prose, for the lost *Sailor's Kalender*, in which he must after some fashion have told of his sea adventures. During the last decade of the century he produced a *farrago* of literary products — a *Juvenal*, if not a very "Young Juvenal" at least in the readiness of his wit and in the robustness of his moral indignation. In conjunction with Greene he produced, in a popular vein, the odd but far from feeble play of *A Looking Glasse for London and England*. Probably about the same time he wrote his *Tragedy of the Wounds of Civil War* lately set forth in the *True Tragedies of Marius and Sylla* (published 1594), a good second-rate piece in the fashion of its age, and deficient neither in rhetorical nor in comic vigour. His *Life and Death of William Longbeard* (1593), and his *History of Robin the Devil*, are among his contemporary non-dramatic works, to which should be added *Phillis* (1593), a collection of lyrical pieces, and a *Fig for Momus* (on the strength of which he has been rather loosely termed the earliest English satirist). In his later years, — possibly about 1596, when he published his *Wife Metrie*, which is dated from Low Leyton, and the prose *Prosopopeia* (if, as seems probable, it was his), in which he repents him of his "lewd lines" of other days, — he was engaged in the practice of madrigals, for which he said to have qualified himself by a degree at Avignon. His works henceforth have a sober cast, comprising a translation of Josephus (1602) and another of Seneca (1614), besides a *Treatise of the Plague* (1603), and a popular manual, still in manuscript, on *Domestic Medicine*. He was abroad on urgent private affairs of one kind or another in 1616, from which time to his death from the plague, in 1625, nothing further concerning him remains to be noted. His life is one of those which attract the curiosity of the literary student, who knows that it is precisely in the mental and moral phases and experiences of able and active men devoid of original genius, such as he, that much of the history of an age of literature is to be read.

Lodge's works have not yet been completely reprinted, though the satisfaction of this want may no longer be far distant. His *Rosaguide* is accessible in Hazlitt's *Shakespeare's Library* (vol. ii.) and elsewhere. Its relation to Shakespeare's comedy is exhaustively discussed in an essay by Delius in the *Jahrbuch of the German Shakespeare Society* (1871). Other works of his are scattered through the publications of the old Shakespeare, the Huntarian, and recently other Societies; lists of them will be found in the edition of *Glaucus and Silla*, &c., printed at the Chiswick Press in 1836, in Hazlitt, and elsewhere. The question, *Was Thomas Lodge an Actor?* has been set at rest by Dr. C. M. Ingham in his pamphlet bearing that title (1869), of which the main conclusion is embodied in this notice. (A. W. W.)

LODI, a city of Italy, in the province of Milan, lies on the right bank of the Adda, in 45° 18' N. lat. and 9° 30' E. long. The site of the city is an eminence rising very gradually from the Lombard plain, and the surrounding country is one of the richest dairy districts in Italy. A rather plain and unquaintly cathedral (1158) with a huge lateral tower, the church dell' Incurazione erected by Bramante in 1476, the Palazzo Modagnani with a fine gateway in the style of Bramante, the episcopal palace dating from 1202, and the great hospital with its cloistered quadrangle, are the most noteworthy buildings. Besides an extensive trade in cheese (Lodi making more Parmesan than Parma itself) and other dairy produce, there are manufactures of linen, silk, majolica, and chemicals. The population of the city in 1871 was 16,537.

The ancient Lusa Pompeia lay about 5 miles west of the present city, and the site is still occupied by a considerable village, Lodi Vecchio. In the 11th century, according to Landulphus Junior, Lodi was second to Milan among the cities of northern Italy. A dispute with the archbishop of Milan about the investiture of the bishop of Lodi (1094) provoked the beginning of a bitter and protracted feud between the two cities. In 1111 the Milanese laid the whole place in ruins and forbade their rivals to restore what they had destroyed, and in 1168, when in spite of this prohibition a fairly flourishing settlement had again been formed, they repeated their work in a more thorough manner. The Lodienses, who had settled on Colle Eghezzone; and their village, the Borgo d'Isella, soon grew up under the patronage of Frederick Barbarossa into a new city of Lodi. At first subservient to the emperor, Lodi was before long compelled to enter the Lombard League, and in 1188 it formed alliance offensive and defensive with Milan. The strife between the Somaschi or aristocratic party and the Overgianschi or democratic party was so severe that the city broke into two distinct communes. The Overgianschi, expelled in 1226, were restored by Frederick II. who took the city after three months' siege. During the rest of the Guelph and Ghibelline struggle, and down to the beginning of the 16th century, the annals of Lodi are crowded with stirring events, connected for the most part with the general troubles of the country. In the main it was dependent on Milan. The duke of Brunswick captured it in 1626 in the interests of Spain; and it was occupied by the French (1701), by the Austrians (1706), by the king of Sardinia (1738), by the Austrians (1758), by the Spaniards (1745), and again by the Austrians (1786). On 10th May 1796 was fought the battle of Lodi between the Austrians and Napoleon, which made the latter master of Lombardy.

LODZ (Lode), a town of Russian Poland, in the province of Piotrkow, lies 40 miles by rail to the north of the chief town of the province, on a branch railway of the line between Warsaw and Vienna. Only a small hamlet with 800 inhabitants in 1821, when its woollen manufactures were first introduced by Germans, it is now the second town of Poland, both by population and by the importance of its cotton-mills, the annual production of which amounts to a value of about £150,000, that is, five-sixths of the whole production of cottons in Poland. This, as well as the other less important industries of the place (woollen cloth manufacture, dyeing, and so on), is chiefly in the hands of Germans, and thus the German language predominates in the town. Although its population in 1873 amounted to 60,500, Lodz still maintains its village character, consisting of one broad street 7 miles long, on which are situated alike the factories, the houses of the merchants, and the dwellings of the working men.

LOFOTEN AND VESTERAALEN, a "fogdæti" or bailiwick in the "amt" of Nordland, Norway, consists of a large

and picturesque group of islands lying north-east and south-west off the north-west coast of Norway, between $67^{\circ}30'$ and $69^{\circ}20'$ N. lat., and between 13° and $16^{\circ}35'$ E. long. The extreme length of the group from Andenes, at the north of Andø, to Røst, is about 150 English miles, the aggregate area amounts to about 1560 square miles, supporting a permanent population of about 20,000. It is separated from the mainland by the Vestfjord, Tjeldsund, and Vægsfjord, and is itself divided into two sections by the Raftsund between Hinder and Ost-Vaagø, to the west and south of the Raftsund lie the Lofoten Islands proper, of which the most important are Ost-Vaagø, Gimsø, Vest-Vaagø, Flakstadø, Moskenesø, Mosken, Værø, and Røst, east and north of the Raftsund are the islands of Vesterålen, the chief being Hinder, Ulvø, Langø, Skogø, and Andø. The islands, which are all of granite or metamorphic gneiss, are precipitous and lofty; the highest peaks are in the Lofoten group, Vaagøkalen on Ost-Vaagø rising directly from the sea to a height of 5090 feet. The channels which separate them are narrow and tortuous, and generally of great depth; they are remarkable for the strength of their tidal currents, particularly the Raftsund mentioned above, and the once famous Malström or Moskenström between Moskenes and Mosken. Though situated wholly within the Arctic Circle, the Lofoten and Vesterålen group enjoys a climate that cannot be called rigorous when compared with that of the rest of Norway. The isothermal line which marks a mean January temperature of 32° F. runs south from the Lofotens, passing a little to the east of Bergen onwards to Gothenburg and Copenhagen. The prevailing winds are those from the south and west, the mean temperature for the year is $38^{\circ}5$ F. and the annual rainfall is 43.94 inches. In summer the hills have only patches of snow, the snow limit being about 3000 feet. The natural pasture produced in favourable localities permits the rearing of cattle to some extent; but the growth of cereals (chiefly barley, which here matures in ninety days) is insignificant. A few potatoes are planted. The islands yield no wood. The great and characteristic industry of the district, and an important source of the national wealth, is the cod fishery which is carried on along the east coast of the Lofotens in the Vestfjord from January to April. It employs about 18,000 men from all parts of Norway; the annual take of cod amounts to an average of twenty millions, worth on the spot about £250,000. The fish, which is dried during early summer, is exported principally to Spain (where it is known as bacalao), but also to Holland, Sweden, and Belgium. Other industries arising out of the fishery are the manufacture of cod-liver oil and of artificial manure. The summer cod fisheries and the lobster fishery are also valuable. The herring is frequently taken in large quantities off the west coasts of Vesterålen, but is a somewhat capricious visitant. The balliwick contains no towns properly so called, but Kabelvaag on Ost-Vaagø and Svolvær on a few rocky islets off that island are considerable centres of trade and (in the fishing season) of population; Lødingen also, at the head of the Vestfjord on Hinder, is much frequented as a port of call. Regular means of communication are afforded by the steamers which trade between Hamburg or Christiania and Hammerfest, and also by local vessels; less accessible spots can be visited by means of boats, in the management of which the natives are adepts. There are some roads on Hinder, Langø, and Andø. The largest island in the group, and indeed in Norway, is Hinder, with an area of 864 square miles. The south-eastern portion of it belongs to the amt of Tromsø. In the island of Andø there is a bed of coal at the mouth of Ramsa which is likely to prove ultimately of some practical value.

LOG. The ordinary log for ascertaining the speed of a ship consists of four parts, viz., the log-glass, log-line, log-reel, and log-skip. The word log may have been derived from the fact that a piece of wood was thrown overboard, to lie as a log in a fixed position, motionless; now the same name is applied to many contrivances and ingenious inventions for indicating directly, or for registering, the ship's progress through the water.

Though such information now appears to be so essential, nay, imperatively necessary to the safe conduct of a ship, it is a fact that no such simple means as the log and line was devised before the 17th century, or the subject even thought of theoretically before 1570. At least nothing can be found in ancient writings, or even in the works professedly treating upon navigation, till after 1620, while, on the contrary, various passages occur from which we may fairly infer that there was nothing better at the command of the mariner than a rough unassisted estimate. The work of Martín Cortes (Sevilla, 1556), after giving much valuable information for that day, including a description and use of the cross-staff, astrolabe, &c., a table of the sun's declination, with much else, makes no other reference to the ship's motion through the water than this—the pilot must estimate the distance, making allowance for the effects of winds and currents, every day, and as the estimation "is imperfect, especially in a long voyage and long time, it is convenient that he should rectify his position by the corresponding position of the heavens." Mr. J. Tapp, who published a translation and improved edition of Martín Cortes fifty-three years after (1609), made no alteration in that part of the work.

In 1578 William Bourne published *Inventions and Devices*. There are one hundred and thirteen subjects treated of, many of them highly interesting, as they contain the crude germ of useful inventions. The twenty-first device is a close approach to Massey's self-registering log, which was found so useful two hundred and sixty years later. The credit of the device is ascribed to Humphry Cole; the probable date is 1570. The proposal was to have a "little small close boat" with a wheel, and an astrolabe, to turn clock-work in the little boat, with dials and pointers to indicate respectively fathoms, leagues, scores of leagues, and hundreds of leagues. If a small screw rotator had been used instead of a wheel, this might have been a great success. It was only a suggestion, perhaps untried; and in common with so many and written about that time the author allows only 5000 feet to a mile. Edward Wright's *Certain Errors in Navigation detected and corrected* (1610) gives much new and useful information, but the nearest allusion to the ship's speed is in the part translated from the Spanish of Rodrigo Samorano, under the head of finding the ship's place on the chart, called the "point of imagination." "This point doth presuppose the knowledge of two things: to wit, the rhumb by which we have sailed, and that is known by the compass, and the leagues which we have run; and this hath no certainty, but is a little more or less than a good mariner according to his imagination supposeth that he hath sailed; whereof the said point took its name." In 1624 an edition of Gunter by Edward Weever, after much valuable geometric information, proposes at chap. vi, in a long rambling manner, that an account should be kept of the ship's way. "The way that a ship maketh may be known to an old seaman by experience, by others it may be found," as he recommends, with the log-line or by known marks on the ship's side, bearing the proportion to a league or mile, that a certain number of seconds do to an hour. So far good; but he reckons a mile as 5886 feet (214 to a little), and states that seamen count in paces of 5 feet each, and 1000 to a mile, i.e., only 5000 feet. He also proposes to

divide the degrees into one hundred parts, each to be called "centesimas." The whole subject is treated as a new thing. It is stated by Purchas (1633) that Christopher Columbus (1493) deceived his crew with respect to the distance sailed from home, and that "even the pilots did not know how far they had gone" as they glided so smoothly with a continuous fair wind. Had any kind of log been here, the ship's speed would have been publicly known. Mr. Burnaby (*United Geography*, p. 534) states that "no ancient writer has preserved any account of the mode in which ancient navigators computed distance." Following such an authority and the quotations above, we may safely agree with the statement of Purchas that it was first used in 1607. Also we know that it did not become general till many years after. In one of our best works on navigation, printed in 1813, the log is inaccurately described.

If we are surprised that so many centuries passed, and that long voyages were made, after the discovery of the compass, without any means of measuring the distance sailed, we may be almost as much so at the diversity of opinion which prevailed among seamen with regard to the length of the log-line and the length of a mile. At the present day the pumple upon which this log is arranged is easily understood. The mean degree of the meridian (see vol. x. p. 198) is assumed to be 60.09 statute miles, which gives 6080 feet to the mean nautical mile,—an estimate sufficiently accurate for navigating upon any part of the sphere. The distance upon the log line being marked by pieces of line placed between the strands and carrying the requisite number of knots, this has given the name of knot to the nautical mile. The line is marked to knots and half knots (a single knot only), the intermediate fractions are estimated. Two measurements are now in common use, that in the British navy is 17 feet 3 inches of line for each knot made per hour, which corresponds with a twenty-eight second glass,—thus (28 x 6080) = 3600 = 47,238 feet; in the merchant service a knot is 50 feet 7 inches, which is the correct proportion to a mile with the half minute glass. When a ship is going more than five or six knots, a short glass is used, fourteen or fifteen seconds, then the indications by the line are doubled. The shorter measure was probably chosen in consequence of the custom in vogue till about 1833 of making the run on the log-board, or book, in knots and fathoms (or sea furlongs), the fractions are now invariably entered as tenths. The whole length of line is 60 to 80 fathoms, according to the speed anticipated, 10 to 20 fathoms of which is allowed as stay line, that the log-ship may be in a fair position, before the rag of bunting called the turn mark passes the hand. The line should be stretched and well wet before it is measured, and should be remeasured every day at sea. The inner end of the line is made fast to a light reel upon which it is wound.

The "log-ship" (fig. 1) is a piece of wood about $\frac{1}{2}$ inch thick and the fourth part of a circle, having a radius of 5 or 6 inches, weighted with lead round the curve in order to keep it upright in the water, but not to sink it. Two holes are bored, about $1\frac{1}{2}$ inches from the lower angles, through one a short piece of line is passed and knotted; the other end of the line has a bone or hard peg spliced to it, which is inserted in the other hole, thus forming a span by which it is attached to the log-line, and hangs square.

When the log is used, a man holds the reel over his head, the officer places the peg in the log-ship, and throws it well clear of the wake, then allows it to run the "stray

line" off without assistance, steadying it just before the turn mark comes to hand, as the mark passes he calls to his assistant with the glass to "turn." As the sand runs out freely till the word "stop" is expected, then bring the line into a state of tension similar to what it was in when the turn mark passed. At the word "stop" nip the line instantly, count the nearest knots, and estimate the tenths. When the line is stopped the strain should cause the peg to draw from the log-ship, and it can easily be hauled in. In ships of war it is hoisted every hour. The value of the operation depends, of course, entirely upon the care bestowed.

Ground-Log.—In large rivers, such as the Rio de la Plata, where a strong current runs, and shoals are found out of the sight of land, a lead of four or five pounds weight is used instead of the log-ship; the lead rests on the bottom, the line and sand-glass being used in a manner similar to that above described. This is called the ground-log, and indicates the speed at which the ship is passing over the ground, irrespective of currents or tides. It will show also the lateral effect of current as it is hauled in, this is the only log which can do so.

The sand-glasses are very primitive contrivances for measuring the requisite number of seconds; they are much affected by damp and change of temperature, and no reliance can be placed on their accuracy. In 1868 a timepiece sounding a gong at the required intervals was devised by the late Admiral Sir Walter Raleigh, and was tried on board some of Her Majesty's ships, but failed after a short time from damp or other causes. The writer of this article was then attempting to produce a log-gong, but abandoned it on being told that they could be obtained below his estimated cost.

Scow Log.—In 1725 Henry de Saumarez described a machine which was to supersede the ordinary log. This was on the principle of the scaw, having vanes which caused it to revolve and communicate a rotary motion to a piece of rope, this most probably went inboard to clockwork, hence the failure. Mr. Saumarez made many experiments about 1751, he found the results very irregular, especially at high velocities, just as the writer of this article did with one of Massey's flies and a line or rope attached to a spar, supported by large friction rollers inboard, both experiments were done failures on account of the friction. In 1778 two scaw logs were tried on board H. M. ship "Rachess" during a short voyage to the Polar Sea; each was made to communicate motion to a counter inboard. In 1792 Mr. Gower took out a patent for a scaw log. None of these experiments were sufficiently successful to gain the confidence of seamen.

We see that the principle was not new in 1834 when Mr. Massey patented a scaw log, which has been generally adopted that it deserves special notice and description. Though Massey took out other patents, and others have followed with modifications, the principle of all is the same, and likely to remain in use with the "common log" for many years to come. Massey fitted his log to the stern of a few vessels, a vertical spindle conveying the rotations of the fly to a register in the cabin above, but it did not answer.

The log of 1836 which came into general use is represented in fig. 2. It consists of two parts united by 2 or 3 feet of rope. The "fly" consists of a hollow copper cylinder about 9 or 10 inches long with four fins or blades placed at a given angle, causing it to rotate once in a certain distance. The rope is attached to the fly and to a spindle which freely revolves in a brass box, an endless screw acting upon a system of wheel-work records the fractions of a mile on one dial, turns upon a second, and runs up to one hundred on the third, on the same principle with the index of a gas meter.

The last patent was for the "frictionless log" shown in fig. 3, which is similar to the former except that, by dispensing with the piece of rope and part of the heavy box, it is much more compact and less liable to foul,—an accident to which all logs when towed after a ship are very liable. Walker's harpoon log is very similar

Fig. 1.

Fig. 2.

Fig. 3.

to the list of Massey's, but has a plate at the back in the shape of a luncheon to prevent the upper part from revolving. This log is now supplied to Her Majesty's ships. The fins or blades which cause the rotation in each of the logs above described are flat pieces of brass (not portions of a screw) soldered to a cylinder, which is hollow in order to diminish the tendency to sink when going slowly, but if the log be left overboard when the ship stops, the tow-line will allow it to sink about 100 feet, the pressure of water will then fill it, and there is no means provided for getting the water out. Screw logs will also at low speeds hang obliquely and be useless. Mr. Fidler tried a log with paddles protruding from a brass box instead of using a screw, but the plan was not adopted. However accurate the registering logs may be, an ordinary log cannot be dispensed with, unless the ship be on one course during the whole twenty-four hours, at her speed be uniform; even then the old log and line should not be neglected. Both Massey and Walker are now trying logs the rotations of which are towed, while the dials for registering are on the ship's stern.

Pressure Log.—In 1840 the Rev R. L. Baiton patented a log (fig. 4), indicating the speed of the ship by means of the pressure of water due to the velocity acting upon a tube about 2 of an inch diameter in the close, closed at the end, protruding some 8 inches below the ship's bottom, with an aperture of about an 8 of an inch in diameter in the front end, near the closed end. A vane was used to turn the aperture in the direction of the ship's progress (course and heave combined). At the upper end of the tube a small pointer indicated the amount of heave. To take into account the effect which change of draught would produce, another pipe was used having the aperture in a vertical direction (4120) with regard to the ship's progress, so that the water was neither forced in nor drawn out. The two pipes communicated with air-vessels, which were allowed to be about half full of water. thence two flexible tubes conveyed the pressure to the ends of an inverted syphon partly filled with mercury, one leg of which forms a glass index tube, a glass scale being placed behind it, graduated upon the principle that the pressure will increase according to the square of the velocity. As the specific gravity of mercury is so great, the scale even up to 16 knots is brought within a convenient compass, and it can be hung in gimbals (as a barometer) in any part of the ship. This velocity indicator in more recent fittings has been abandoned. The water of this article first saw it in one of the Jersey packets, when she was steaming about 13 knots, it appeared to be very sensitive, and he was strongly impressed in its favour. For details respecting this log see paper by Vaughan Pendered, before the Society of Engineers, December 6, 1869.

The motions or disturbances imparted to the water by the body of the ship passing through it at high velocity must vitiate in a great degree all attempts to measure the speed by instruments placed near the hull of the ship, and under varying circumstances of draught, speed, and foulness of bottom. For the results of experiments and opinions on this point, see the *Whitaker's Rep.*, p. 235, and Mr. R. Edmund Froude, see *Brit. Assoc. Rep.*, 1874, p. 236, and 1879, p. 210.

Electric Log.—In the chronological order in which we have taken various descriptions of logs, the last deserving notice is Kelway's "electric log," the only such log known to the public. Its chief feature is the making and breaking of an electric circuit by means of a screw passing in the water and an electric battery connected with the step motion indicator. One of the difficulties

to be overcome was that of securing a chamber wherein to form the electric contacts, which should remain watertight under the pressure due to its depth below the surface of the sea, particularly in the event of the ship stopping and suffering it to sink when being towed with 50 fathoms of line. Mr. Kelway now believes that he has overcome that difficulty, and his log has been tried on board several of Her Majesty's ships at Portsmouth, with satisfactory results, a screw similar to Massey's being towed, while in electric connexion with a dial on board.

What is considered by Mr. Kelway to be an improved application of the principle is now (1882) on view in the International Exhibition at the Crystal Palace. It is intended that a hole should be cut in the ship's bottom, by preference in the engine-room, large enough to allow a short cylinder (fig. 5) containing the screw to pass down below the ship's bottom. The cylinder is open in a fore-and-aft line and attached to a cage II, which is drawn up or lowered by means of a large screw C working through a stuffing box F. The iron box D containing the cage is 4 feet in height, made in three parts, the lower part (high enough to receive a sluice valve C) is to be bolted to the ship's bottom, and must, with the rest of the box, be nearly as strong, the central part is secured to the valve box and covered by a lid E, this being space enough above the sluice valve to set the cage and screw.

To place the log, let the sluice valve C be lightly closed; open two small taps to let the water out of the box and to prove that the valve is acting. Open the lid, run the lowering screw through the cage, place it, secure the lid, open the sluice valve, and lower the rotation to the desired standard. The index of the rotation is a portion of a true screw. An endless screw on the spindle of the rotation communicates the revolutions to a vertical spindle M, which moves a train of wheels in a watertight box N, the last of these wheels revolves once in a mile, and on the same spindle is a wheel having eight ratchet teeth, which by moving a lever complete an electric circuit, which passes by the wire O to a dial placed in any part of the ship, sounding a bell and causing one hand of the dial to make a stop and mark an eighth, one revolution indicates a mile, and other dials only the register up to 100 miles. This form of electric log has, however, the disadvantage pointed out as affecting the electric current, or any log placed under the hull of a ship.

The electric towing log (by Kelway) promises to show continuously on board the ship what she is doing, while keeping a record of what has been done. A rating table would be at the dial, in any part of the ship, or several dials could be worked by the same electric current. It will be exposed to the danger of fouling seaweed, &c., as other towing logs are.

The logs now generally used are Massey's, Walker's, and a few of Baiton's, generally in conjunction with the old log-ships and line. (H. A. M.)

LOGAN, JOHN (1748-88), a Scottish poet of some reputation, was born in 1748, and was son of George Logan, a farmer at Soutra, in East Lothian. Being destined for the church, he was in 1762 sent to study at the university of Edinburgh. After finishing his course, Logan was in 1768-69 tutor at Ulbster to the well-known Sir John Sinclair, and in 1770 he edited some of the poems of his college friend MICHAEL BRUCE (*q.v.*). This publication was for the benefit of Bruce's parents, who were in humble circumstances. In order to make up a volume he inserted some poems of his own, with some from other sources, and in his preface he stated that these could be easily distinguished without any names being attached. Of the seventeen pieces in the volume five were by Bruce, two by Bruce and Logan, eight by Logan, one by Sir James Foulis, and of one the authorship is unknown. One of the poems by Logan was "The Ode to the Cuckoo."

In 1770 Logan was licensed as a preacher by the presbytery of Edinburgh, and in 1771 was presented to the charge of South Leith, but was not inducted till 1773. In 1779 he delivered a course of lectures on the philosophy of history in St. Mary's Church, Edinburgh. An analysis of these lectures was published in 1781 under the title of *Elements of the Philosophy of History*, and was followed by one of the lectures *On the Manners and Government of Asia*, 1781.

Logan was an active member of the committee of the General Assembly of the Church of Scotland appointed in 1775 to revise the "Translations and Paraphrases" drawn up in 1745 for use in private families, and to adapt them for public worship. The committee described its

Fig. 4

Fig. 5

labours in 1781, and their collection of paraphrases is still in use. Eleven of them are the composition of Logan, and others were revised or altered by him. In the same year he published his poems in a volume which attracted so much attention that a second edition was issued in 1782. It also included the "Ode to the Cuckoo," with which Edmund Burke was so pleased that when in Edinburgh he sought out Logan and complimented him as the author of the finest ode in the English language.

In 1783 he published a tragedy called *Ruxamede*, which met with little success. In 1786 he resigned his charge at South Leith, retaining part of his stipend. He then went to London, where he devoted himself to literature. He was engaged on the management of the *English Review*, and in 1788 published a pamphlet on the charges against Warren Hastings. He died in December 1788.

A work on ancient history, published that year under the name of Dr. Rathenold, rector of an academy at Uabridge, is believed to have been the lectures written by Logan. His sermons were published in 1790-91, in two volumes, and have been several times reprinted. His poems were collected and published in 1812, with a memoir understood to be by the Rev. R. Douglas of Galashiels.

About forty years after Logan's death what may be called the Bruce-Logan controversy arose by the publication in 1884 of a life of Michael Bruce, prefixed to an edition of his poems by the Rev. Dr. MacKilvie. In this work there is claimed for Bruce the authorship of sixteen of the pieces in the volume issued by Logan in 1770. Logan was at the same time charged with having returned some of Bruce's MSS. entrusted to him, which he used in the revision of the paraphrases. These statements have been reiterated with much abuse of Logan in a memoir of Bruce prefixed to an edition of his works published in 1895, by the Rev. Dr. Gosset. In this edition the paraphrases written by Logan are inserted as having been written by Bruce. The evidence, however, brought against Logan in these biographies of Bruce, being nearly altogether of a hearsay character, is not of much value, and it may be said that Logan was not blamed during his life for any such literary delinquencies. If anything can be brought against him with justice, it is his publishing as his own, with very few alterations, the second Pamphlet, which is the composition of Dr. Doddridge.

Within the last few years the various pieces in the volume of Bruce's poems issued by Logan in 1770 have been subjected to careful criticism, and the statements made from personal knowledge by the Rev. Dr. Robertson of Dalmeny, the college friend of Bruce and Logan, who was often referred to on the subject, must be held to be substantially correct. These will be found in a brochure by Dr. David Laing, *Ode to the Cuckoo* (Edinburgh 1770), with remarks on its authorship, in a letter to J. C. Sharpe, LL.D., 1878. See also a paper by J. Small in the *Brit. and For. Rev.* Nov., 1877, and especially two papers by the Rev. R. Small, *ibid.*, 1878.

LOGANSPOUT, capital of Cass county, Indiana, U.S., is situated at the confluence of the Wabash and the El rivers, and on the Wabash and Erie canal, 75 miles north-west of Indianapolis. It is an important railway junction, and the trading-centre of an extensive agricultural district—dealing in grain, pork, and timber (poplar and black walnut). The Pittsburgh, Cincinnati, and St. Louis railroad maintains at this point large carriage-works, occupying 25 acres, and employing 600 men. The population was 11,198 in 1880.

LOGARITHMS The definition of a logarithm is as follows:—if a, x, m are any three quantities satisfying the equation $a^x = m$, then a is called the base, and x is said to be the logarithm of m to the base a . This relation between a, x, m , may be expressed also by the equation $x = \log_a m$.

Properties.—The principal properties of logarithms are given by the equations

$$\log_a (mn) = \log_a m + \log_a n, \quad \log_a \frac{m}{n} = \log_a m - \log_a n,$$

$$\log_a m^r = r \log_a m, \quad \log_a \sqrt[r]{m} = \frac{1}{r} \log_a m,$$

which may be readily deduced from the definition of a logarithm. It follows from these equations that the logarithm of the product of any number of quantities is equal to the sum of the logarithms of the quantities, that the logarithm of the quotient of two quantities is equal

to the logarithm of the numerator diminished by the logarithm of the denominator, that the logarithm of the r th power of a quantity is equal to r times the logarithm of the quantity, and that the logarithm of the r th root of a quantity is equal to $\frac{1}{r}$ th of the logarithm of the quantity.

Logarithms were originally invented for the sake of abbreviating arithmetical calculations, as by their means the operations of multiplication and division may be replaced by those of addition and subtraction, and the operations of raising to powers and extraction of roots by those of multiplication and division. For the purpose of thus simplifying the operations of arithmetic, the base is taken equal to 10, and use is made of tables of logarithms in which the values of x , the logarithm, corresponding to values of m , the number, are tabulated. The logarithm is also a function of frequent occurrence in analysis, being regarded as a known and recognized function like $\sin x$ or $\tan x$; but in mathematical investigations the base generally employed is not 10, but a certain quantity usually denoted by the letter e , of value 2.71828 18284 . . .

Thus in arithmetical calculations if the base is not expressed it is understood to be 10, so that $\log m$ denotes $\log_{10} m$, but in analytical formulae it is understood to be e .

The logarithms to base 10 of the first twelve numbers to 7 places of decimals are

$\log 1 = 0.0000000$	$\log 5 = 0.6989700$	$\log 9 = 0.9542425$
$\log 2 = 0.3010800$	$\log 6 = 0.7781513$	$\log 10 = 1.0000000$
$\log 3 = 0.4771213$	$\log 7 = 0.8450980$	$\log 11 = 1.0413927$
$\log 4 = 0.6020600$	$\log 8 = 0.9030900$	$\log 12 = 1.0791812$

The meaning of these results is that

$$1 = 10^0, \quad 2 = 10^{0.3010800}, \quad 3 = 10^{0.4771213}, \quad \dots$$

$$10 = 10^1, \quad 11 = 10^{1.0413927}, \quad 12 = 10^{1.0791812}, \quad \dots$$

The integral part of a logarithm is called the index or characteristic, and the fractional part the mantissa. When the base is 10, the logarithms of all numbers in which the digits are the same, no matter where the decimal point may be, have the same mantissa; thus, for example,

$$\log 25618 = 0.4084604, \quad \log 25618 = 1.4084604,$$

$$\log 2561800 = 6.4084604, \text{ \&c.}$$

In the case of fractional numbers (δ), numbers in which the integral part is 0) the mantissa is still kept positive, so that, for example,

$$\log 25618 = \bar{1}.4084604, \quad \log .0025618 = \bar{5}.4084604, \text{ \&c.}$$

the minus sign being usually written over the characteristic, and not before it, to indicate that the characteristic only and not the whole expression is negative; thus

$$\bar{1}.4084604 \text{ stands for } -1 + .4084604.$$

The fact that when the base is 10 the mantissa of the logarithm is independent of the position of the decimal point in the number affords the chief reason for the choice of 10 as base. The explanation of this property of the base 10 is evident, for a change in the position of the decimal points amounts to multiplication or division by some power of 10, and this corresponds to the addition or subtraction of some integer in the case of the logarithm, the mantissa therefore remaining intact. It should be mentioned that in most tables of trigonometrical functions, the number 10 is added to all the logarithms in the table in order to avoid the use of negative characteristics, so that the characteristic 9 denotes in reality 1, 8 denotes 2, 10 denotes 0, &c. Logarithms thus increased are frequently referred to for the sake of distinction as *tabular logarithms*, so that the tabular logarithm—the true logarithm + 10.

In tables of logarithms of numbers to base 10 the mantissa only is in general tabulated, as the characteristic of the logarithm of a number can always be written down at sight, this rule being that, if the number is greater than

unity, the characteristic is less by unity than the number of digits in the integral portion of ix , and that if the number is less than unity the characteristic is negative, and is greater by unity than the number of cyphers between the decimal point and the first significant figure.

It follows very simply from the definition of a logarithm that

$$\log_a b \times \log_b a = 1, \quad \log_a m = \log_a m \times \frac{1}{\log_a b}.$$

The second of these relations is an important one, as it shows that from a table of logarithms to base a , the corresponding table of logarithms to base b may be deduced by multiplying all the logarithms in the former by the constant multiplier $\frac{1}{\log_a b}$, which is called the *modulus* of the system whose base is b with respect to the system whose base is a .

The two systems of logarithms for which extensive tables have been calculated are the Napierian, or hyperbolic, or natural system, of which the base is e , and the Briggsian, or decimal, or common system, of which the base is 10, and we see that the logarithms in the latter system may be deduced from those in the former by multiplication by the constant multiplier $\frac{1}{\log_e 10}$, which is called the modulus of the common system of logarithms. The numerical value of this modulus is 0.43429 44819 03251 83765 11389 ..., and the value of its reciprocal, $\log_{10} e$, 10 (by multiplication by which Briggsian logarithms may be converted into Napierian logarithms) is 2.30258 50929 94045 68401 79914 ...

The quantity denoted by e is the series,

$$1 + \frac{1}{1} + \frac{1}{2} + \frac{1}{2 \cdot 2} + \frac{1}{3 \cdot 2 \cdot 2} + \frac{1}{4 \cdot 2 \cdot 2 \cdot 2} + \dots$$

the numerical value of which is,

$$2.71828 18284 59045 23536 02874 \dots$$

The mathematical function $\log x$, or $\log_e x$, is one of the small group of transcendental functions, consisting only of the circular functions (direct and inverse) $\sin x$, $\cos x$, $\&c.$, arc $\sin x$, arc $\cos x$, $\&c.$, e^x , and $\log x$, which are universally treated in analysis as known functions. It is the inverse of the exponential function e^x , the theory of which may be regarded as including that of the circular functions, since

$$\sin x = \frac{1}{2i} (e^{ix} - e^{-ix}), \quad \cos x = \frac{1}{2} (e^{ix} + e^{-ix}).$$

There is no series for $\log x$ proceeding either by ascending or descending powers of x , but there is an expansion for $\log(1+x)$, viz. —

$$\log(1+x) = x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \frac{1}{4}x^4 + \&c.;$$

the series, however, is convergent for real values of x only when x lies between +1 and -1. Other formulae which are deducible from this equation are given in the portion of this article relating to the calculation of logarithms.

We have also the fundamental formulae—

$$(i.) \text{ Limit of } \frac{x^h - 1}{h}, \text{ when } h \text{ is indefinitely diminished,} = \log x;$$

$$(ii) \int \frac{dx}{x} = \log x + \text{const.}$$

Either of these results might be regarded as the definition of $\log x$; they may be readily connected with one another, for we have in general

$$\int \frac{dx}{x} = \frac{x^{a+1}}{a+1} + \text{const.};$$

but if $a = -1$, this formula no longer gives a result. Putting, however, $a = -1 + h$, where h is indefinitely small, we have

$$\int \frac{dx}{x} = \frac{x^{a+1}}{h} + \text{const.} = \frac{x^h - 1}{h} + \text{const.} = \log x + \text{const. by (i).}$$

The result (ii) establishes a relation, which is of historical interest, between the logarithmic function and the quadrature of the hyperbola, for, by considering the equation of the hyperbola in the form $xy = \text{const.}$, we see at once that the area included between the arc of a hyperbola, its nearest asymptote, and two ordinates drawn parallel to the other asymptote from points on the first

asymptote distant a and b from their point of intersection is proportional to $\log \frac{b}{a}$.

The function $\log x$ is not a *uniform* function, that is to say, if x denotes a complex variable of the form $a+ib$, and if complex quantities are represented in the usual manner by points in a plane, then it does not follow that if x describes a closed curve $\log x$ also describes a closed curve; in fact we have

$$\log(a+ib) = \log \sqrt{(a^2+b^2)} + i(a+2\pi n),$$

where a is a determinate angle, and n denotes any integer. Thus, even when the argument is real, $\log x$ has an infinite number of values, for, putting $b=0$ and taking a positive, in which case $a=0$, we obtain for $\log a$ the infinite system of values $\log a + 2\pi ni$. It follows from this property of the function that we cannot have for $\log x$ a series which shall be convergent for all values of x , as is the case with $\sin x$, $\cos x$, and e^x , as such a series could only represent a uniform function, and in fact the equation

$$\log(1+x) = x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \frac{1}{4}x^4 + \&c.,$$

is true only when the analytical modulus of x is less than unity.

The notation $\log x$ is generally employed in English works, but Continental writers usually denote the function by $\lg x$ or \lg_e .

History.—The invention of logarithms has been accorded to John Napier, baron of Merchiston, in Scotland, with a unanimity which is rare with regard to important scientific discoveries. The first announcement was made in Napier's *Mirifici logarithmorum canonis descriptio* (Edinburgh, 1614), which contains an account of the nature of logarithms, and a table giving natural sines and their logarithms for every minute of the quadrant to seven or eight figures. These logarithms are not what now be called Napierian or hyperbolic logarithms (i.e. logarithms to the base e), though closely connected with them, the relation between the two being

$$e = 10^L \log_e 10, \text{ or } L = 10^L \log_e 10, 10^L = 10^L,$$

where L denotes the logarithm to base e and L denotes Napier's logarithm. The relation between N (a sine) and L its Napierian logarithm is therefore

$$N = 10^N \frac{1}{10^L},$$

and the logarithms decrease as the sines increase. Napier died in 1617, and his posthumous work *Mirifici logarithmorum canonis constructio*, explaining the mode of construction of the table, appeared in 1619, edited by his son.

Henry Briggs, then professor of geometry at Gresham College, London, and afterwards Savilian professor of geometry at Oxford, admired the *Canon mirificus* so much that he resolved to visit Napier. In a letter to Usher he writes, "Napier, lord of Merchiston, hath set my head and hands at work with his new and admirable logarithms. I hope to see him this summer, if it please God; for I never saw a book which pleased me better, and made me more wonder." Briggs accordingly visited Napier in 1616, and stayed with him a whole month. He brought with him some calculations he had made, and suggested to Napier the advantages that would result from the choice of 10 as a base, having explained them previously in his lectures at Gresham College, and written to Napier on the subject. Napier said that he had already thought of the change, and pointed out a slight improvement, viz. that the characteristics of numbers greater than unity should be positive and not negative, as suggested by Briggs. In 1616 Briggs again visited Napier and showed him the work he had accomplished, and, he says, he would gladly have paid him a third visit in 1617 had Napier's life been spared.

Briggs's *Logarithmorum canonis prima* was published, probably privately, in 1617, after Napier's death, as in the short preface he states that why his logarithms are different from those introduced by Napier "aperandum, ejus librum posthummum abunde nobis propediem satisfieturum." The *liber posthummus* was the *Canonis constructio* already mentioned. This work of Briggs's, which contains the

first published table of decimal or common logarithms, is only a small octavo tract of sixteen pages, and gives the logarithms of numbers from unity to 1000 to 14 places of decimals. There is no author's name, place, or date. The date of publication is, however, fixed as 1617 by a letter from Sir Henry Bourchier to Ussher, dated December 6, 1617, containing the passage—"Our kind friend, Mr Briggs, hath lately published a supplement to the most excellent tables of logarithms, which I presume he has sent to you." Briggs's tract of 1617 is extremely rare, and has generally been ignored or incorrectly described. Hutton erroneously states that it contains the logarithms to 8 places, and his account has been followed by most writers. There is a copy in the British Museum.

Briggs continued to labour assiduously at the calculation of logarithms, and in 1624 published his *Arithmetica logarithmica*, a folio work containing the logarithms of the numbers from 1 to 20,000, and from 90,000 to 100,000 (and in some copies to 101,000) to 14 places of decimals. The table occupies 300 pages, and there is an introduction of 88 pages relating to the mode of calculation of the tables, and the applications of logarithms.

There was thus left a gap between 20,000 and 90,000, which was filled up by Adrian Vlacq, who published at Gouda, in Holland, in 1628, a table containing the logarithms of the numbers from unity to 100,000 to 10 places of decimals. Having calculated 70,000 logarithms and copied only 30,000, Vlacq would have been quite entitled to have called his a new work. He designates it, however, only a second edition of Briggs's *Arithmetica logarithmica*, the title running *Arithmetica logarithmica sive logarithmorum chiliadas centum, . . . Editio secunda aucta per Adrianum Vlacq, Goudanum*. This table of Vlacq's was published, with an English explanation prefixed, at London in 1631 under the title *Logarithmicki Arithmetike . . . London, printed by George Miller, 1631*. There are also copies with a French title page and introduction (Gouda, 1629).

Briggs had himself been engaged in filling up the gap, and in a letter to Pell, written after the publication of Vlacq's work, and dated October 25, 1628, he says:—

"My desire was to have these chiliades that are wanting betwixt 20 and 90 calculated and printed, and I had done them all almost by my self, and by some friends whom my rules had sufficiently informed, and by agreement the business was conveniently parted amongst us; but I am eased of that charge and care by one Adrian Vlacq, an Hollander, who hath done all the whole hundred chiliades and printed them in Latin, Dutche, and French, 1000 books in these 8 languages, and hath sold them almost all. But he hath cutt off 4 of my figures throughout; and hath left out my dedication, and to the reader, and two chapters the 12 and 13, in the rest he hath not varied from me at all."

The original calculation of the logarithms of numbers from unity to 101,000 was thus performed by Briggs and Vlacq between 1615 and 1628. Vlacq's table is that from which all the hundreds of tables of logarithms that have subsequently appeared have been derived. It contains of course many errors, which have gradually been discovered and corrected in the course of the two hundred and fifty years that have elapsed, but no fresh calculation has been published. The only exception is Mr Sang's table (1871), part of which was the result of an original calculation.

The first calculation or publication of Briggian or common logarithms of trigonometrical functions was made in 1620 by Gunter, who was Briggs's colleague as professor of astronomy in Gresham College. The title of Gunter's book, which is very scarce, is *Canon triangulorum*, and it contains logarithmic sines and tangents for every minute of the quadrant to 7 places of decimals.

The next publication was due to Vlacq, who appended to his logarithms of numbers in the *Arithmetica logarithmica*

of 1638 a table giving log sines, tangents, and secants for every minute of the quadrant to 10 places; these were obtained by calculating the logarithms of the natural sines, &c., given in the *Theaurus Mathematicus* of Pitiscus (1613).

During the last years of his life Briggs devoted himself to the calculation of logarithmic sines, &c., and at the time of his death in 1631 he had all but completed a logarithmic canon to every hundredth of a degree. This work was published by Vlacq at his own expense at Gouda in 1633, under the title *Trigonometria Britannica*. It contains log sines (to 14 places) and tangents (to 10 places), besides natural sines, tangents, and secants, at intervals of a hundredth of a degree. In the same year Vlacq published at Gouda his *Trigonometria artificialis*, giving log sines and tangents to every 10 seconds of the quadrant to 10 places. This work also contains the logarithms of the numbers from unity to 20,000 taken from the *Arithmetica logarithmica* of 1628. Briggs appreciated clearly the advantages of a centesimal division of the quadrant, and by dividing the degree into hundredth parts instead of into minutes, made a step towards a reformation in this respect, and but for the appearance of Vlacq's work the decimal division of the degree might have become recognized, as is now the case with the corresponding division of the second. The calculation of the logarithms not only of numbers but also of the trigonometrical functions is therefore due to Briggs and Vlacq; and the results contained in their four fundamental works—*Arithmetica logarithmica* (Briggs), 1624; *Arithmetica logarithmica* (Vlacq), 1628; *Trigonometria Britannica* (Briggs), 1633; *Trigonometria artificialis* (Vlacq), 1633—have never been superseded by any subsequent calculations.

A translation of Napier's *Descriptio* was made by Edward Wright, whose name is well known in connexion with the history of navigation, and after his death published by his son at London in 1616 under the title *A Description of the admirable Table of Logarithmes* (12mo); the edition was revised by Napier himself. Both the *Descriptio* (1614) and the *Constructio* (1619) were reprinted at Lyons in 1620 by Bartholomew Vincent, who thus was the first to publish logarithms on the Continent.

Napier calculated no logarithms of numbers, and, as already stated, the logarithms invented by him were not to base e . The first logarithms to the base e were published by John Speidell in his *New Logarithmes* (London, 1619), which contains hyperbolic log sines, tangents, and secants for every minute of the quadrant to 5 places of decimals.

In 1624 Benjamin Ursinus published at Cologne a canon of logarithms exactly similar to Napier's in the *Descriptio* of 1614, only much enlarged. The interval of the arguments is 10', and the results are given to 8 places; in Napier's canon the interval is 1', and the number of places is 7. The logarithms are strictly Napierian, and the arrangement is identical with that in the canon of 1614. This is the largest Napierian canon that has ever been published.

Kepler took the greatest interest in the invention of logarithms, and in 1624 he published at Marburg a table of Napierian logarithms of sines, with certain additional columns to facilitate special calculations.

The first publication of Briggian logarithms on the Continent is due to Wingate, who published at Paris in 1635 his *Arithmétique logarithmique*, containing seven-figure logarithms of numbers up to 1000, and log sines and tangents from Gunter's *Canon* (1620). In the following year, 1636, Denis Hamion published at Paris a *Traité des Logarithmes*, containing Briggs's logarithms of numbers up to 20,001 to 10 places, and Gunter's log sines and tangents to 7 places for every minute. In the same year De Decker also published at Gouda a work entitled *Nieuwe Tekonst, inhoudende de Logarithmi voor de Gheallen beginnende van*

1 to 10,000, which contained logarithms of numbers up to 10,000 to 10 places, taken from Briggs's *Arithmetica* of 1624, and Gunter's log sines and tangents to 7 places for every minute. Vlacq rendered assistance in the publication of this work, and the privilege is made out to him.

The preceding paragraph contains a brief account of the main facts relating to the invention of logarithms. In describing the contents of the works referred to the language and notation of the present day have been adopted, so that for example a table to radius 10,000,000 is described as a table to 7 places, and so on. Also, although logarithms have been spoken of as to the base e , &c., it is to be noticed that neither Napier nor Briggs, nor any of their successors till long afterwards, had any idea of connecting logarithms with exponents.

The invention of logarithms and the calculation of the earlier tables form a very striking episode in the history of exact science, and, with the exception of the *Principia* of Newton, there is no mathematical work published in the country which has produced such important consequences, or to which so much interest attaches as to Napier's *Description*. The calculation of tables of the natural trigonometrical functions may be said to have formed the work of the last half of the 16th century, and the great canon of natural sines for every 10 seconds to 15 places which had been calculated by Rheticus was published by Pitiscus only in 1613, the year before that in which the *Description* appeared. In the construction of the natural trigonometrical tables England had taken no part, and it is remarkable that the discovery of the principles and the formation of the tables that were to revolutionize or supersede all the methods of calculation then in use should have been so rapidly effected and developed in a country in which so little attention had been previously devoted to such questions.

The only possible rival to Napier in the invention of logarithms is Justus Byrgius, who about the same time constructed a rude kind of logarithmic or rather anti-logarithmic table; but there is every reason to believe that Napier's system was conceived and perfected before that of Byrgius; and in date of publication Napier has the advantage by six years. The title of the work of Byrgius is *Arithmetische und geometrische Progress-Tabulen*; in his table he has log 1 = 0 and log 10 = 230270022. The only contemporary reference to Byrgius is contained in the sentence of Kepler, "Apices logarithici Justo Byrgio multis annis ante editionem Neperianam viam preceperunt ad hos ipseiusmodi logarithmos," which occurs in the "Præcepta" prefixed to the *Tabulae Rudolphinae* (1627); the apices are the signs ":", used to denote the orders of sexagesimal fractions. The system of Byrgius is greatly inferior to that of Napier, and it is to the latter alone that the world is indebted for the knowledge of logarithms. The claims of Byrgius are discussed in Kistner's *Geschichte der Mathematik*, vol. ii. p. 375, and vol. iii. p. 14; Montucla's *Histoire des Mathématiques*, vol. ii. p. 10; Delambre's *Histoire de l'Astronomie moderne*, vol. i. p. 560; De Morgan's article on "Tables" in the *English Cyclopædia*; and Mr Mark Napier's *Memoirs of John Napier of Merchiston* (1834).

An account of the facts connected with the early history of logarithms is given by Hutton in his *History of Logarithms*, prefixed to all the early editions of his logarithmic tables, and also printed in vol. i. pp. 306-340 of his *Tracts* (1812); but unfortunately Hutton has interpreted all Briggs's statements with regard to the invention of decimal logarithms in a manner clearly contrary to their true meaning, and unfair to Napier. This has naturally produced retaliation, and Mr Mark Napier has not only successfully refuted Hutton, but has fallen into the opposite extreme of attempting to reduce Briggs to the level of a mere com-

puter. It seems strange that the relations of Napier and Briggs with regard to the invention of decimal logarithms should have formed matter for controversy. The statements of both agree in all particulars, and the warmest friendship subsisted between them. Napier at his death left his manuscripts to Briggs, and all the writings of the latter show the greatest reverence for him. The words that occur on the title page of the *Logarithmical arithmetike* of 1631 are "These numbers were first invented by the most excellent John Neper, Baron of Merchiston; and the same were transformed, and the foundation and use of them illustrated with his approbation by Henry Briggs." No doubt the invention of decimal logarithms occurred both to Napier and to Briggs independently; but the latter not only first announced the advantage of the change, but actually undertook and completed tables of the new logarithms. For more detailed information relating to Napier, Briggs, and Vlacq, and the invention of logarithms, the reader is referred to the life of Briggs in Ward's *Lives of the Professors of Gresham College*, London, 1740, Thomas Smith's *Vita quorundam eruditissimorum et illustrium virorum* (Vita Henrici Briggsii), London, 1707; Mr Mark Napier's *Memoirs of John Napier* already referred to, and the same author's *Naperi libri qui superant* (1839); Hutton's *History*; De Morgan's article already referred to; Delambre's *Histoire de l'Astronomie Moderne*; the report on mathematical tables in the *Report of the British Association* for 1873; and the *Philosophical Magazine* for October and December 1872 and May 1873. It may be remarked that the date usually assigned to Briggs's first visit to Napier is 1616 and not 1615 as stated above, the reason being that Napier was generally supposed to have died in 1618; but it was shown by Mr Mark Napier that the true date is 1617.

For a description of existing logarithmic tables, and the purposes for which they were constructed, the reader is referred to the article TABLES (MATHEMATICAL). In what follows only the most important events in the history of logarithms, subsequent to the facts connected with their invention and the original calculations, will be noticed.

Nathaniel Roe's *Tabulae logarithmicæ* (1638) was the first complete seven-figure table that was published. It contains seven-figure logarithms of numbers from 1 to 100,000, with characteristics appended from the mantissa, and was formed from Vlacq's table (1628) by leaving out the last three figures. All the figures of the number are given at the heads of the columns, except the last two, which run down the extreme columns—1 to 50 on the left hand side, and 50 to 100 on the right hand side. The first four figures of the logarithms are printed at the tops of the columns. There is thus an advance half way towards the strangely now universal eight-figure tables. The final step was made by John Newton in his *Trigonometria Britannica* (1668), a work which is also noticeable as being the only extensive eight-figure table that has ever been published; it contains logarithms of sines, &c., as well as logarithms of numbers.

In 1705 appeared the original edition of Sherwin's tables, the first of the series of ordinary seven-figure tables of logarithms of numbers and trigonometrical functions such as are in general use now. The work went through several editions during the last century, and was at length superseded in 1786 by Hutton's tables, which have continued in successive editions to maintain their position up to the present time.

In 1717 Abraham Sharp published in his *Geometry Improved* the Briggsian logarithms of numbers from 1 to 100, and of primes from 100 to 1100, to 61 places; these were copied into the later editions of Sherwin and other works.

In 1743 a seven-figure table was published in quarto form by Gardiner, which is celebrated on account of its accuracy, and of the elegance of the printing. A French edition, which closely resembles the original, was published at Avignon in 1770.

In 1758 appeared at Paris the first edition of Gallot's tables, which correspond to those of Hutton in England. These tables, which form perhaps the most complete and practically useful collection of logarithms for the general computer that has been published, have passed through many editions, and are still in use.

In 1764 Vega published his *Thesaurus logarithmorum completus*, a folio volume containing a reprint of the logarithms of numbers

from Vlacq's *Arithmetica logarithmica* of 1628, and *Trigonometria arithmetica* of 1633. The logarithms of numbers are arranged as in an ordinary seven-figure table. In addition to the logarithms reprinted from the *Trigonometria*, etc., there are given logarithms for every second of the first two degrees, which were the result of an original calculation. Vega devoted great attention to the detection and correction of the errors in Vlacq's work of 1628. He also published in 1797, in 3 vols. 8vo., a collection of logarithmic and trigonometrical tables which has passed through many editions, a very useful one volume stereotype edition having been published in 1840 by Hulise. The tables in this work may be regarded as so complete and supplementary to those of Callet.

It we consider only the logarithms of numbers, the main line of descent from the original calculation of Briggs and Vlacq is Roe, John Newton, Sherwin, Gardiner, there also then two branches, viz., Hutton founded on Sherwin and Callet on Gardiner, and the editions of Vega form a separate offshoot from the original tables. Among the most useful and accessible of modern ordinary seven-figure tables of logarithms of numbers and trigonometrical functions may be mentioned those of Riemeier, Schron, and Bruhns. For logarithms of numbers only perhaps Babbage's table is the most convenient.

In 1811 Mr Sang published a seven-figure table of logarithms of numbers extending from 20,000 to 200,000; and the logarithms of the numbers between 100,000 and 200,000 were calculated *de novo* by Mr Sang as if logarithms had never been computed before. In tables extending from 10,000 to 100,000 the differences near the beginning of the table are large, and they are so numerous that the proportional parts must either be very crowded, or some of them have to be omitted, and to diminish this inconvenience many tables extend to 108,000. By beginning the table at 20,000 instead of at 10,000, the differences are halved in magnitude, while the number of them in a page is quartered. In this table multiple of the differences, instead of in proportional parts, are given.

As regards the logarithms of trigonometrical functions, the next great advance on the *Trigonometria arithmetica* took place more than a century and a half afterwards, when Michael Taylor published in 1792 his seven-decimal table of log sines and tangents to every second of the quadrant. It was calculated by interpolation from the *Trigonometria* to 10 places and then contracted to 7. On account of the great size of this table, and for other reasons, it never came into very general use. Bagny's *Nouvelles tables des sinusques* (1829), which also contains log sines and tangents to every second, being smaller. In this table was a serious defect to be pointed out. The only other logarithmic canon to every second that has been published forms the second volume of Shorthead's *Logarithmic Tables* (1849). It contains also proportional parts, and is the most complete and accessible table of logarithms for every second. Shorthead's tables originally appeared in 1844 in one volume, during the author's absence in India; but, not being satisfied with them in some respects, he made various alterations, and published a second edition in two volumes in 1849. There have been subsequent editions of the volumes containing the trigonometrical canon. The work is an important one, and the pages are clear, although the number of figures on each is very great.

On the proposition of Carnot, Prier, and Brunet, the French Government decided in 1784 that new tables of sines, tangents, &c., and their logarithms, should be calculated in relation to the centesimal divisions of the quadrant. Frany was charged with the direction of the work, and was expressly required "Non seulement à composer des tables qui ne laissent rien à désirer quant à l'exactitude, mais à en faire le monument de calcul le plus vaste et le plus important qui ait jamais été exécuté on même genre."

These engaged on the work were divided into three sections: the first consisted of one or six mathematicians, including Legendre, who were engaged in the purely analytical work, or the calculation of the fundamental numbers; the second section consisted of seven or eight calculators possessing some mathematical knowledge; and the third comprised seventy or eighty ordinary computers. The work, which was performed in the greatest haste, and independently by two divisions of computers, occupied two years. As a consequence of the double calculation, there are two manuscripts in existence, one of which is deposited at the Observatory, and the other in the library of the Institute, at Paris. Each of the two manuscripts consists of seventeen large folio volumes, the contents being as follows:

Logarithms of numbers up to 100,000	8 vols.
Natural sines	1 "
Logarithms of the ratios of areas to areas from 0° 00' 00" to 0° 59' 00", and log sines throughout the quadrant	1 "
Logarithms of the ratios of arcs to tangents from 0° 00' 00" to 0° 59' 00", and log tangents throughout the quadrant	4 "

The trigonometrical results are given for every hundred-thousandth of the quadrant (10" centesimal or 8" 24' sexagesimal). The tables were all calculated to 14 places, with the intention that only 12 should be published, but the twelfth figure is not to be relied upon. The tables have never been published, and are

generally known as the *Tables du Cadastre*; or, in England, as the great French manuscript tables.

A very full account of the *Tables du Cadastre*, with an explanation of the methods of calculation, formulas employed, &c., has been published by M. Lefort in vol. iv. of the *Annales de l'Observatoire de Paris*. The printing of the table of natural sines was once begun, and M. Lefort states that he has seen six copies, all incomplete, although including the last page. Babbage computed his table with the *Tables du Cadastre*, and M. Lefort has given in his paper just referred to most important lists of errors in Vlacq's and Bagny's logarithms of numbers which were obtained by comparing the manuscript tables with those contained in the *Arithmetica logarithmica* of 1624 and of 1638. These are almost the only uses that have been made of the French tables, the calculation of which involved so great an expenditure of time and money.

It may be mentioned here that the late Mr John Thomson of Greenock made an independent calculation of the logarithms of numbers up to 120,000 to 12 places, and that the manuscript of the table was presented in 1874 to the Royal Astronomical Society by his master. The table has been used to verify the sines which M. Lefort found in Vlacq and Briggs by means of the *Tables du Cadastre*. An account of Mr Thomson's table, and of this and other comparisons between it and the printed tables, is to be found in the *Monthly Notices of the Society*, vol. xxvii pp. 447-76 (1874).

Although the *Tables du Cadastre* have never been published, other tables have appeared in which the quadrant is divided centesimally, the most important of these being Robert and Lidel's *Nouvelles tables trigonométriques* (1799), and Borda and Delambre's *Tables trigonométriques décimales* (1800-1). The former work contains natural and log sines, cosines, tangents, and cotangents to 7 places, up to 3° (centesimal) at intervals of 10" (centesimal), and thence to 60° at intervals of 1'. The latter gives log sines, cosines, tangents, and cosecants for centesimal arguments, viz., from 0° to 10° at intervals of 10", and from 10° to 60° at intervals of 10", to 11 places, and also, in another table, log sines, cosines, tangents, cotangents, secants, and cosecants from 0° to 3° at intervals of 10", and thence to 60° at intervals of 1' to 7 places. After the work was printed it was revised by Delambre with the *Tables du Cadastre*, and a number of last-figure errors which are given in the preface were thus detected. Callet's tables already referred to contain in a convenient form logarithms of trigonometrical functions for centesimal arguments.

Two tables of logarithms of numbers which have been recently published may be noticed, as they involve points of novelty. The first of these is Puot's *Tables de logarithmes* (St Petersburg, 1871). The tables are intended to give in a small space (56 pages) all the results that can be obtained from a complete ten-figure table by means of the following principle:—only the logarithms of the numbers from 1,000,000 to 1,911,000 are given. The logarithms of numbers being brought within the range of this table by multiplication by a factor, the logarithm of which factor is to be subtracted from the logarithm in the table. A list of the most convenient factors and their logarithms is given in a separate table. The principle of multiplying by a factor which is subsequently cancelled by subtracting its logarithm, is one that is frequently employed in the calculation of logarithms, but the peculiarity of the present work is that it forms part of the process of using the table. The other tables, which occupy only ten pages, were published in a tract entitled *Tables de logarithmes à 12 décimales, jusqu'à 434 millions* by MM. Namur and Mansion at Brussels in 1876. The fact that the differences of the logarithms of numbers near to 434294 (these being the first figures of the modulus of the Bignian logarithms) commenced with the figure 100, so that the interpolations in this part of the table are very easily and accurately performed, was ingeniously made use of. The only other extensive tables of numbers near to 434294, and other numbers are brought within the range of the table by multiplication by one or two factors which are indicated.

In the ordinary tables of logarithms the natural numbers are all integers, while the logarithms tabulated are incommensurable. In an antilogarithmic table, the logarithms are exact quantities such as 0.0001, 0.0002, &c., and the numbers are incommensurable. The earliest and largest table of this kind that has been constructed is Dodson's *Antilogarithmic canon* (1748), which gives the numbers to 11 places, corresponding to the logarithms from 0.0001 to .9999 at intervals of 0.0001. The only other extensive tables of the same kind that have been published occur in Shorthead's *Logarithmic tables* already referred to, and in Filipowicz's *Table of antilogarithms* (1849). Both are similar to Dodson's tables, from which they were derived, but they only give numbers to 10 places.

The most elaborate table of hyperbolic logarithms that exists is due to Wylfahm, a Dutch mathematician. It has been given in the logarithms of all numbers up to 3200, and of primes, and also of a great many composite numbers from 2200 to 10,000, to 48 decimal places. The table appeared in Schulze's *Neue und erweiterte Sammlung logarithmischer Tafeln* (1778), and was reprinted in Vega's *Thesaurus* (1794), already referred to. Six

logarithms omitted in Schulze's work, and which Wolfiam had been prevented from computing by a serious illness, were published subsequently, and the table as given by Vega is complete. The largest hyperbolic table as regards range was published by Zacharias Dase at Vienna in 1860 under the title *Tafel der natürlichen Logarithmen der Zahlen*. It gives hyperbolic logarithms of numbers from 10000 to 106000 at intervals of 1 to 7 places, with differences and proportional parts, arranged like an ordinary seven-figure table of Briggsian logarithms. The table appeared in the thirty-fourth part (new series, vol. xiv) of the *Annals of the Vienna Observatory* (1861), but separate copies were issued.

Hyperbolic arithmetics are simple exponentials, i.e., the hyperbolic antilogarithm of x is e^x . A seven-figure table of e^x and its Briggsian logarithm from $x = 0.1$ to $x = 10$ at intervals of 0.1 is given in Hulse's edition of Vega's *Sammlung*, and in other collections of tables; but by far the most complete table that has been published occurs in Gudermann's *Theorie der potestativ-als cyklisch-hyperbolischen Functionen*, Berlin, 1833. This work consists of reprinted papers from Crelle's *Journal*, and one of the tables contains the Briggsian logarithms of the hyperbolic sine, cosine, and tangent of x from $x = 2$ to $x = 5$ at intervals of 0.01 to 9 places, and from $x = 5$ to $x = 12$ at intervals of 0.01 to 10 places. Since the hyperbolic sine and cosine of x are respectively $\frac{1}{2}(e^x - e^{-x})$ and $\frac{1}{2}(e^x + e^{-x})$, the values of e^x and e^{-x} may be deduced from the results given in the table by simple addition and subtraction.

Logistic numbers is the old name for what would now be called ratios or fractions. Thus a table of $\log \frac{a}{x}$, where x is the argument and a a constant, is called a table of logistic or proportional logarithms, and since $\log \frac{a}{x} = \log a - \log x$ it is clear that the tabular results differ from those given in an ordinary table of logarithms only by the subtraction of a constant and a change of sign. The first table of this kind appeared in Kepler's *Chilias logarithmorum* (1624) already referred to. The object of a table of $\log \frac{a}{x}$ is to facilitate the working out of proportions in which the third term is a constant quantity a . In most collections of tables of logarithms, and especially those intended for use in connexion with navigation, there occurs a small table of logistic logarithms in which $a = 3600$ ($= 1^\circ \times 12$), the table giving $\log 3600 - \log x$, and x being expressed in minutes and seconds. It is also common to find tables in which $a = 108000$ ($= 8^\circ \times 3^\circ$), and x is expressed in degrees (or hours), minutes, and seconds. Such tables are generally given to 4 or 5 places. The usual practice in books seems to be to call logarithmic logs when a is 3600, and proportional when a has any other value.

Gaussian logarithms are intended to facilitate the finding of the logarithms of the sum and difference of two numbers whose logarithms are known, the numbers themselves being unknown, and on this account they are frequently called addition and subtraction logarithms. The object of the table is in fact to give $\log(a \pm b)$ by only one entry when $\log a$ and $\log b$ are given. The utility of such logarithms was first pointed out by Leonelli in a book entitled *Supplement logarithmicum*, printed at Bordeaux in the year XI. (1802-3); this work being very scarce, a reprint of it was published by M. J. Houel in 1876. Leonelli calculated a table to 14 places, but only a specimen of it which appeared in the *Supplement* was printed. The first table that was actually published is due to Gauss, and was printed in *Zach's Monatshefte Correspondenz*, vol. xxv, p. 498 (1813). Corresponding to the argument A it gives, to 5 places, B and C , where

$$A = \log x, \quad B = \log \left(1 + \frac{1}{x} \right), \quad C = \log(1+x).$$

so that $C = A + B$.

We have identically

$$\log(a+b) = \log a + \log \left(1 + \frac{b}{a} \right) = \log a + B \text{ (for argument } \log \frac{a}{b} \text{),}$$

and, in using the table, the rule is to take $\log a$ to be the larger of the two logarithms, and to enter the table with $\log a - \log b$ for argument; we then have $\log(a+b) = \log a + B$, or, if we please, $= \log b + C$. The formulae for the difference is $\log(a-b) = \log b + A$ (argument sought in column C) if $\log a - \log b$ is greater than 86108 and $= \log b - A$ (argument sought in column B) if $\log a - \log b$ is less than 86108.

The principal tables of Gaussian logarithms are (1) *Matheseos, Tafel zur begyneren Berechnung* (Altona, 1818), giving B and C for argument A to 7 places—this table is not a convenient one; (2) *Peter Gray, Tables and Formulae* (London, 1849), and *Addendum* (1870), giving full tables of B and $\log(1-x)$ for argument A to 6 places; (3) *Zach, Tafeln der Addition- und Subtraction-Logarithmen* (Leipzig, 1849), giving 7-place values of B for argument A , and 7-place values of C for argument B . These tables appeared originally in Hulse's edition of Vega's *Sammlung* (1849); (4)

Wittstein, *Logarithmus de Gauss* (Hanover, 1866), giving values of B for argument A to 7 places. This is a large table, and the arrangement is similar to that of an ordinary seven-figure table of logarithms.

In 1829 Widenbach published at Copenhagen a small table of modified Gaussian logarithms giving $\log \frac{x+1}{x-1}$ ($= D$) corresponding

to A as argument. A and D are thus reciprocal, the relation between them being in fact $10^{A+D} = 10^A + 10^D + 1$, so that either A or D may be regarded as the argument.

Gaussian logarithms are chiefly useful in the calculations connected with the solution of triangles in such a form as $\cot \frac{1}{2}C = \frac{a+b}{a-b} \tan \frac{1}{2}(A-B)$, and in the calculation of life contingencies $a - b$.

Calculation of Logarithms.—The name logarithm is derived from the words $\lambda \gamma \alpha \nu$ $\delta \rho \alpha \mu \acute{o} \varsigma$, the number of the ratios, and the way of regarding a logarithm which justifies the name may be explained as follows. Suppose that the ratio of 10, or any other particular number, to 1 is compounded of a very great number of equal ratios, as for example 1,000,000, then it can be shown that the ratio of 2 to 1 is very nearly equal to a ratio compounded of 301,030 of these small ratios, or *ratiunculae*, that the ratio of 3 to 1 is very nearly equal to a ratio compounded of 477,121 of them, and so on. The small ratios, or *ratiunculae*, is in fact that of the millionth root of 10 to 1, and if we denote it by the ratio of a to 1, then the ratio of 2 to 1 will be nearly the same as that of $a^{301,030}$ to 1, and so on; or, in other words, if a denotes the millionth root of 10, then 2 will be nearly equal to $a^{301,030}$, 3 will be nearly equal to $a^{477,121}$, and so on.

Napier's original work, the *Descriptio canonis* of 1614, contained, not logarithms of numbers, but logarithms of sines, and the relations between the sines and the logarithms were explained by the motions of points in lines, in a manner not unlike that afterwards employed by Newton in the method of fluxions. An account of the processes by which Napier constructed his table is given in the *Constructio canonis* of 1619. These methods apply, however, specially to Napier's own kind of logarithms, and are different from those actually used by Briggs in the construction of the tables in the *Arithmetica logarithmica*, although some of the latter are the same in principle as the processes described in an appendix to the *Constructio*. It may be observed that in the *Constructio* logarithms are called artificial, and this seems to have been the name first employed by Napier, but which he subsequently replaced by logarithms. It is to be presumed that he would have made the change of name also in the *Constructio*, had he lived to publish it himself.

The processes used by Briggs are explained by him in the preface to the *Arithmetica logarithmica* (1624). His method of finding the logarithms of the small primes, which consists in taking a great number of continued geometric means between unity and the given primes, may be described as follows. He first formed the table of numbers and their logarithms:

Number.	Logarithm.
10	1
3.162277 . . .	0.5
1.778279 . . .	0.25
1.333821 . . .	0.125
1.154781 . . .	0.0625

each quantity in the left hand column being the square root of the one above it, and each quantity in the right hand column being the half of the one above it. To construct this table Briggs, using about thirty places of decimals, extracted the square root of 10 fifty-four times, and then found that the logarithm of 1.0000000000000000 12781 91493 20382 85 was 0.0000000000000000 06951 1112 81267 82702, and that for numbers of this form ($\frac{1}{2^n}$), for numbers beginning with 1 followed by fifteen ciphers, and

then by seventeen or a less number of significant figures) the logarithms were proportional to these significant figures. He then by means of a simple proportion deduced that $\log(1.00000\ 00000\ 00000\ 1) = 0.00000\ 00000\ 00000\ 04342\ 94481\ 90325\ 1804$, so that, a quantity 1.00000 00000 00000 x (where x consists of not more than seven figures) having been obtained by repeated extraction of the square root of a given number, the logarithm of 1.00000 00000 00000 x could then be found by multiplying x by .00000 00000 00000 04342

To find the logarithm of 2, Briggs raised it to the tenth power, viz., 1024, and extracted the square root of 1.024 forty-seven times, the result being 1.00000 00000 00000 16851 60570 53946 77. Multiplying the significant figures by 4343 . . . he obtained the logarithm of this quantity, viz., 0.00000 00000 00000 07318 55936 90633 9336, which multiplied by 247 gave 0.01639 99566 39811 95265 277444, the logarithm of 1024, true to 17 or 18 places. Adding the characteristic 3, and dividing by 10, he found (since 2 is the tenth root of 1024) $\log 2 = .30102\ 99566\ 63981\ 195$. Briggs calculated in a similar manner $\log 3$, and thence deduced $\log 5$.

It will be observed that in the first process the value of the modulus is in fact calculated from the formula

$$\frac{h}{10^4 - 1} = \frac{1}{\log_{10} 10}.$$

the value of h being $\frac{1}{247}$, and in the second process $\log_{10} 2$ is in effect calculated from the formula

$$\log_{10} 2 = \left(\frac{10}{2^{10} - 1} \right) \times \frac{1}{\log_{10} 10} \times 2^9.$$

Briggs also gave methods of forming the mean proportionals or square roots by differences; and the general method of constructing logarithmic tables by means of differences is due to him.

The following calculation of $\log 5$ is given as an example of the application of the method of mean proportionals. The process consists in taking the geometric mean of numbers above and below 5, the object being to at length arrive at 5.000000. To every geometric mean in the column of numbers there corresponds the arithmetical mean in the column of logarithms. The numbers are denoted by $A, B, C, &c.$, in order to indicate their mode of formation.

	Numbers	Logarithms.
$A =$	1.000000	0.0000000
$B =$	10.000000	1.0000000
$C = \sqrt{AB}$	3.162277	0.5000000

Great attention was devoted to the methods of calculating logarithms during the 17th and 18th centuries. The earlier methods proposed were, like those of Briggs, purely arithmetical, and for a long time logarithms were regarded from the point of view indicated by their name, that is to say,

as depending on the theory of compounded ratios. The introduction of infinite series into mathematics effected a great change in the modes of calculation and the treatment of the subject. Besides Napier and Briggs, special reference should be made to Kepler (*Chilias*, 1634) and Mercator (*Logarithmotechnica*, 1668), whose methods were arithmetical, and to Newton, Gregory, Halley, and Cotes, who employed series. A full and valuable account of these methods is given in Hutton's "Construction of Logarithms," which occurs in the introduction to the early editions of his *Mathematical Tables*, and also forms tract 21 of his *Mathematical Tracts* (vol. i., 1812). Many of the early works on logarithms were reprinted in the *Scriptores logarithmici* of Baron Masereus (6 vols. 4to, 1791-1807).

In the following account only those formulae and methods will be referred to which would now be used in the calculation of logarithms.

Since

$$\log_e(1+x) = x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \frac{1}{4}x^4 + &c.,$$

we have, by changing the sign of x ,

$$\log_e(1-x) = -x - \frac{1}{2}x^2 - \frac{1}{3}x^3 - \frac{1}{4}x^4 - &c.,$$

whence

$$\log_e \frac{1+x}{1-x} = 2(x + \frac{1}{3}x^3 + \frac{1}{5}x^5 + &c.),$$

and, therefore, replacing x by $\frac{p-q}{p+q}$,

$$\log_e \frac{p}{q} = 2 \left\{ \frac{p-q}{p+q} + \frac{1}{3} \left(\frac{p-q}{p+q} \right)^3 + \frac{1}{5} \left(\frac{p-q}{p+q} \right)^5 + &c. \right\},$$

in which the series is always convergent, so that the formula affords a method of deducing the logarithm of one number from that of another.

As particular cases we have, by putting $q=1$,

$$\log_e p = 2 \left\{ \frac{p-1}{p+1} + \frac{1}{3} \left(\frac{p-1}{p+1} \right)^3 + \frac{1}{5} \left(\frac{p-1}{p+1} \right)^5 + &c. \right\},$$

and by putting $q=p+1$,

$$\log_e(p+1) - \log_e p = 2 \left\{ \frac{1}{2p+1} + \frac{1}{3} \left(\frac{1}{2p+1} \right)^3 + \frac{1}{5} \left(\frac{1}{2p+1} \right)^5 + &c. \right\};$$

the former of these equations gives a convergent series for $\log_e p$, and the latter a very convergent series by means of which the logarithm of any number may be deduced from the logarithm of the preceding number.

From the formula for $\log_e \frac{p}{q}$ we may deduce the following very convergent series for $\log_e 2$, $\log_e 3$, and $\log_e 5$, viz. —

$$\log_e 2 = 2(7P + 5Q + 8R),$$

$$\log_e 3 = 2(11P + 8Q + 5R),$$

$$\log_e 5 = 2(16P + 12Q + 7R),$$

where

$$P = \frac{1}{81} + \frac{1}{3} \cdot \frac{1}{(81)^3} + \frac{1}{5} \cdot \frac{1}{(81)^5} + &c.,$$

$$Q = \frac{1}{49} + \frac{1}{3} \cdot \frac{1}{(49)^3} + \frac{1}{5} \cdot \frac{1}{(49)^5} + &c.,$$

$$R = \frac{1}{161} + \frac{1}{3} \cdot \frac{1}{(161)^3} + \frac{1}{5} \cdot \frac{1}{(161)^5} + &c.$$

The following still more convenient formulae for the calculation of $\log_e 2$, $\log_e 3$, and $\log_e 5$ are given by Professor J. O. Adams in the *Proceedings of the Royal Society*, vol. xxvii (1878), p. 61. If

$$a = \log \frac{10}{9} = -\log \left(1 - \frac{1}{10} \right), \quad b = \log \frac{25}{24} = -\log \left(1 - \frac{1}{100} \right),$$

$$c = \log \frac{81}{80} = \log \left(1 + \frac{1}{80} \right), \quad d = \log \frac{50}{49} = -\log \left(1 - \frac{1}{100} \right),$$

$$e = \log \frac{128}{125} = -\log \left(1 + \frac{3}{1000} \right),$$

then

$$\log_e 2 = 7a - 2b + 8c, \quad \log_e 3 = 11a - 3b + 5c, \quad \log_e 5 = 16a - 4b + 7c,$$

and

$$\log_e 7 = \frac{1}{2}(80a - 10b + 17c - d) \text{ or } 12a - 4b + 5c + e,$$

and we have the equation of condition,

$$a - 2b + 8c - d + 5e = 0.$$

By means of these formulae Professor Adams has calculated the values of $\log_e 2$, $\log_e 3$, $\log_e 5$, and $\log_e 7$ to 260 places of decimals,

and he has deduced the value of $\log 10$ and its reciprocal M , the modulus of the Briggsian system of logarithms. The value of the modulus found by Professor Adams is

M =	.43429	44819	93921	82765	11299
	18916	80508	03261	97905	80366
	05691	14458	76816	58646	49208
	87077	47292	24949	33843	17488
	18706	10674	47663	08713	84167
	92871	58963	04656	92320	94992
	81926	55521	27086	56867	08326
	03870	86095	49266	53831	13860
	77384	90514	26443	43865	76864
	05890	86186	56148	21594	87658
	43643	43878	17947	48649	05098
	56858	05			

The values of the other logarithms are given in the paper referred to.

If the logarithm are Briggsian all the series in the preceding formulae must be multiplied by M , the modulus; thus, for example,

$$\log_{10}(1+z) = M(x - \frac{1}{2}x^2 + \frac{1}{3}x^3 - \frac{1}{4}x^4 + \dots),$$

and so on.

As has been stated, Abraham Sharp's table contains 61-decimal Briggsian logarithms of primes up to 1100, so that the logarithms of all composite numbers whose greatest prime factor does not exceed this number may be found by simple addition, and Wolfman's table gives 48-decimal hyperbolic logarithms of primes up to 10,000. By means of these tables and of a factor table we may very readily obtain the Briggsian logarithm of a number to 61 or a less number of places or of its hyperbolic logarithm to 48 or a less number of places in the following manner. Suppose the hyperbolic logarithm of the prime number 48,867 required. Multiplying by 60, we have $60 \times 48,867 = 2,932,020$, and on looking in Burckhardt's *Table des densités* for a number next to this which shall have no prime factor greater than 10,000, it appears that

$$2,932,020 = 23 \times 47 \times 2029;$$

thus

$$48,867 = \frac{1}{23} (23 \times 47 \times 2029),$$

and therefore

$$\log 48,867 = \log 23 + \log 47 + \log 2029 - \log 50$$

$$+ \frac{1}{23,198,849} - \frac{1}{2} \left(\frac{1}{23,198,849} \right)^2 + \frac{1}{3} \left(\frac{1}{23,198,849} \right)^3 - \dots$$

The first term of the series in the second line

$$= 0.00000 04659 28795 07819 6286;$$

dividing this by $2 \times 5,108,849$ we obtain

$$= 0.00000 00000 00108 98325 8457,$$

and the third term is

$$= 0.00000 00000 00000 00008 1590,$$

so that the series =

$$= 0.00000 04659 28691 13997 4419;$$

whence, taking out the logarithms from Wolfman's table,

$$\log 48,867 = 10.68891 76079 60668 10191 3661.$$

The principle of the method is to multiply the given prime (supposed to consist of 4, 5, 6 or 8 figures) by such a factor that the product may be a number within the range of the factor table, and such that, when it is increased by 1 or 2, the prime factors may all be within the range of the logarithm tables. The logarithm is then obtained by use of the formula

$$\log(x+d) = \log x + \frac{d}{x} - \frac{1}{2} \frac{d^2}{x^2} + \frac{1}{3} \frac{d^3}{x^3} - \dots,$$

in which of course the object is to render $\frac{d}{x}$ as small as possible.

If the logarithm required is Briggsian, the value of the series is to be multiplied by M .

If the number is incommensurable or consists of more than seven figures, we can take the first seven figures of it (or multiply and divide the result by any factor, and take the first seven figures of the result) and proceed as before. An application to the hyperbolic logarithm of π is given by Burckhardt in the introduction to his *Table des densités* for the second million.

The best general method of calculating logarithms consists, in its simplest form, in resolving the number whose logarithm is required into factors of the form $1 \pm \frac{1}{n}$, where n is one of the nine digits, and making use of subsidiary tables of logarithms of factors of this form. For example, suppose the logarithm of 848689 required to twelve places. Divided by 10^5 and by 5 the number becomes 1.087678 , and resolving this number into factors of the form $1 \pm \frac{1}{n}$ we find that

$$848689 = 10^5 \times 5(1 - \frac{1}{10})(1 - \frac{1}{40})(1 - \frac{1}{16})(1 - \frac{1}{16})(1 - \frac{1}{16}) \\ \times (1 - \frac{1}{16})(1 - \frac{1}{17})(1 - \frac{1}{17})(1 - \frac{1}{17})(1 - \frac{1}{17})$$

where $1 - \frac{1}{16}$ denotes $1 - .0625$, $1 - \frac{1}{17}$ denotes $1 - .000588$, &c., and so

on. All that is required therefore in order to obtain the logarithm of any number is a table of logarithms, to the required number of places, of $\frac{1}{n}$, $\frac{1}{2n}$, $\frac{1}{3n}$, $\frac{1}{4n}$, &c., for $n=1, 2, 3, \dots, 9$.

The resolution of a number into factors of the above form is easily performed. Taking, for example, the number 1.087678, the object is to destroy the significant figure 8 in the second place of decimals; this is effected by multiplying the number by $1 - \frac{1}{10}$, that is, by subtracting from the number that ninth itself advanced two places, and we thus obtain 1.00068378. To destroy the first 6 multiply by $1 - .0006$ giving 1.00006381744, and multiplying successively by $1 - .00006$ and $1 - .000003$, we obtain 1.000000857692, and it is clear that these last six significant figures represent without any further work the remaining figures required. In the corresponding antilogarithmic process the number is expressed as a product of factors of the form $1 \pm \frac{1}{n}$.

This method of calculating logarithms by the resolution of numbers into factors of the form $1 \pm \frac{1}{n}$ is generally known as Weddle's method, having been published by him in *The Mathematician* for November 1846, and the corresponding method for antilogarithms by means of factors of the form $1 + (\frac{1}{n})^k$ is known by the name of Hearn, who published it in the same journal for 1847. In 1848 Mr Peter Gray constructed a new table to 12 places, in which the factors were of the form $1 - (\frac{1}{17})^k$, so that n had the values 1, 2, 3, 4, 5, and subsequent to this he constructed a similar table for factors of the form $1 - (\frac{1}{17})^k$. He also discovered a method of applying a table of Hearn's form ($1 \pm \frac{1}{n}$) of factors of the form $1 \pm \frac{1}{n}$ to the construction of logarithms, and calculated a table of logarithms of factors of the form $1 \pm (\frac{1}{17})^k$ to 24 places. This was published in 1879 under the title *Tables for the formation of logarithms and antilogarithms to twenty-four or any less number of places*, and contains the most complete and useful application of the method, with many improvements in points of detail. Taking as an example the calculation of the Briggsian logarithm of the number 48,867, whose hyperbolic logarithm has been calculated above, we multiply it by 6 giving 181,602, and find by Mr Gray's process that the factors of 1.81602 are

(1) 1.816	(5) 1.00170003
(2) 1.000007	(6) 1.0017802
(3) 1.0017698	(7) 1.00176412
(4) 1.0017780	(8) 1.0017840.

Taking the logarithms from Mr Gray's tables we obtain the required logarithm by addition as follows—

522	878	745	280	837	562	704	972	=	colog 3
119	255	889	277	936	638	553	918	=	log (1)
	8	040	050	738	157	610	226	=	log (2)
		259	708	022	625	458	597	=	log (3)
			338	749	636	752	424	=	log (4)
					388	538	964	=	log (5)
					261	445	278	=	log (6)
						178	929	=	log (7)
							148	=	log (8)

$$4.442 137 904 655 780 757 298 404 = \log 48,867$$

In Shortrede's *Tables* there are tables of logarithms and factors of the form $1 \pm (\frac{1}{17})^k$ to 16 places and of the form $1 \pm (\frac{1}{17})^k$ to 25 places; and in his *Table des Logarithmes à 27 Digits* (Paris, 1867) Réaumur gives a table of logarithms of factors of the form $1 \pm \frac{1}{n}$. In the *Essayer of Mathematics*, vol. iii, pp. 65-92, 1878, Mr Henry Wace gave a simple and clear account of both the logarithmic and antilogarithmic processes, with tables of both Briggsian and hyperbolic logarithms of factors of the form $1 \pm \frac{1}{n}$ to 20 places.

Although the method is usually known by the names of Weddle and Hearn, it is really, in its essential features, due to Briggs, who gave in the *Arithmetica logarithmica* of 1624 a table of the logarithms of $1 \pm \frac{1}{n}$ up to $n=16$ places of decimals. It was first formally proposed as an independent method, with great improvements, by Robert Flower in *The Essayer, a new way of making Logarithms*, which was published in 1771; and Leonelli, in his *Supplément logarithmique* (1802-8), already noticed, referred to Flower and reproduced some of his tables. A complete bibliography of this method has been given by Mr A. J. Ellis in a paper "On the potential radix as a means of calculating logarithms," printed in the *Proceedings of the Royal Society*, vol. xxii, 1881, pp. 401-407, and vol. xxxii, 1881, pp. 877-879. Reference should also be made to Hoppe's *Tafeln zur dreissigstelligen logarithmischen Rechnung* (Leipzig, 1876), which give in a somewhat modified form a table of the hyperbolic logarithms of $1 \pm \frac{1}{n}$.

The preceding methods are only appropriate for the calculation of isolated logarithms. If a complete table had to be reconstructed, or calculated to more places, it would undoubtedly be most convenient to employ the method of differences. A full account of this method as applied to the calculation of the *Table des Chiffres* is given by M. Lefort in vol. iv of the *Annales de l'Observatoire de Paris*. (J. W. L. G.)

LOGIC

1. LOGIC, in the most general acceptance of the term, may be regarded as the systematic study of thought. So wide a definition is certainly sufficient to comprehend all that may have been at various times included within the scope of logical doctrine, but in other respects it is of small value. It does not serve to mark off logic from philosophy as a whole, which is unquestionably the systematic exposition of thought, nor from psychology, which includes within its wider range what may well be described as the study of thought. Without some more accurate discrimination of the provinces and method of logic, neither the extent of matter to be included within the study nor the peculiarity of the method by which such matter is treated can be determined.

Preliminary queries of a similar kind are naturally encountered in the case of all other branches of human knowledge, and are generally answered by two methods. We may refer either to the distinct characteristics of the matter to be treated, or to the essential features of the method of treatment. We may determine the province of a science either by external division, by classification of objects according to their prevailing resemblances and differences, or by internal definition, by exposition of the fundamental characters of the method employed. By neither process, unfortunately, can an unambiguous answer be supplied, at least without much art, in the case of logic.

2 The reasons for the manifold difficulties encountered in the attempt to determine accurately the province of logic, whether by reference to a division of the sciences or by precise definition of the essential features of logical analysis, are not far to seek. The systematic classification of the sciences involves not only consideration of the contents of the sciences as empirically presented, but also certain leading principles or fundamental views, which are in essence of a philosophical character. According to the general conception of knowledge which in various kinds is manifested in the special sciences, there will be radically divergent methods of classification, and the province assigned to each member of the ensemble will, for the most part, have its limits determined according to the character of the general view adopted. Moreover, if any of the more prominent specimens of classification of the sciences be critically inspected, they will be found to presuppose a certain body of principles, of scope wider than any of the special disciplines, and to which no place in the ensemble can be assigned. In short, a systematic distribution of human knowledge into its distinctly marked varieties rests upon and presupposes a general philosophy, the character of which affects the place and function of each part of the distribution. Logic, as may readily be imagined, has therefore experienced a variety of treatment at the hands of systematizers of scientific knowledge. It has appeared as one of the abstract sciences, in opposition to those disciplines in which the character of the concrete material is the essential fact; as a subordinate branch of a particular concrete science, the investigation of mental phenomena; as a nondescript receptacle for the formulation in generalized fashion of the method and logical precepts exemplified in the special sciences. By such processes no more has been effected than to bring into light, more or less clearly, some of the characteristics of the supposed science, without in any way supplying an exhaustive and comprehensive survey of its boundaries and relations to other branches of knowledge. Thus, when logic is marked off from the concrete sciences and associated with mathematics in the most general sense, as the treatment

of formal relations,¹ and further differentiated from mathematics as implying no reference to the quantitative character of the most general relations under which facts of experience present themselves,² there is certainly brought to the front what one would willingly allow to be a common-place respecting all logical analysis, namely, that its principles are coextensive with human knowledge, and that all objects as matters of conscious experience have an aspect in which they are susceptible of logical treatment. But no more is effected. It is still left to a wider consideration to determine what the specific aspect of things may be which shall be called the *formal* and be recognized as the peculiarly logical element in them. There may be selected for this purpose either the general relations of coincidence and succession in space and time, or the fundamental properties of identity and difference, or the existences of classes, but in any case such selection depends upon and refers to a theory of the nature of knowledge and of the constitution of things as known. In truth, the notions of *form* and *formal relations* are by no means so simple and free from ambiguity that by their aid one can at once solve a complicated problem of philosophic arrangement. To lay stress upon *form* as the special object of logical treatment still leaves undecided the nature and ground of the principles which are to be employed in evolving a science of form, and therefore leaves the logical problem untouched.

Still less satisfactory are the results when logic is regarded as in some way a subordinate branch of the psychological analysis of mental phenomena.³ Neither the grounds on which such a classification rests, nor the conclusions deduced from it, seem beyond criticism. The simple facts that certain mental processes are analysed in logic, and that psychology is generally the treatment of all mental processes, by no means necessitate the view that logic is therefore the outgrowth from and a subordinate part of psychology. For it is clear, on the one hand, that logic has a scope wider than psychology, since in any sense of the term it has to deal with all the processes (or with some aspect of all the processes) by which on any subject knowledge is formed out of disjointed or disconnected experiences. And, on the other hand, since the subordination of one science to another, as species to genus, is fallacious, unless the two agree in fundamental characteristics, the position so assigned to logic would imply that in aim and method it shall be essentially one with psychology, a position equivalent to the negation of logic as a separate and independent discipline. It is not surprising therefore to find that so soon as logic has been distinguished as arising from psychology, and so dependent on it, the peculiarity of its position and functions compels the recognition of its more general scope and the reduction of its connexion with psychology to an amount small enough to be compatible with absolute independence. Strong

¹ *Ans. c.p.*, by H. Spencer, *Classification of the Sciences*, pp. 6, 12; H. Grossmann, *Die Ausdehnungslehre* von 1844 (1878), Einleitung, xxi.—xxii.

² Logic and mathematics, under this view, may be regarded either as generically distinct—which is apparently the opinion of Spencer, H. Grossmann, and Jevons—or as species of a more comprehensive genus, the theory of formal (symbolic) operations—which is apparently the opinion of B. Grossmann (see his *Formenlehre*, 737ff) and Boole (see his *Mathematical Analysis of Logic*, 1847, p. 4, and *Differential Equations*, 1869, chap. xvi., specially pp. 888, 890). An admirable treatment of that which is implied in Boole's method is given in Mr Veit's *Symbolische Logik*, 1891.

³ For this extremely common arrangement, see Hamilton, *Lectures on Metaphysics*, i p. 191–3; Ueberweg, *System der Logik*, § 6.

reasons, indeed, may be advanced for holding that logic is entirely to be separated from psychology, as differing from it in aim, method, and principle, that logical analysis is generically distinct from psychological, and that the two disciplines, while connected as parts of the general body of philosophical reflection, hold to one another a relation the reverse of that commonly accepted.¹

As to the endeavour to collect from consideration of the sciences in detail a body of precepts, the rules of scientific method, and to assign the systematic arrangement of such rules to one special discipline, called logic, it seems to stand on the same footing and to be open to the same criticism as the allied attempt to treat general philosophy as the receptacle for the most abstract propositions reached in scientific knowledge. There is a peculiar assumption underlying the supposed possibility of distinguishing between scientific method and its concrete exemplifications in the special sciences, and only on the ground of this assumption could there be rested the independence of logic as the systematic treatment of method. It is taken for granted, without examination, that the characteristic features of correct and well-founded thinking are palpable and general, and that we thus possess a criterion for marking off what is common to all scientific procedure from that which is special and peculiar to the individual sciences. An elaborate philosophic doctrine lies at the root of this assumption, and the position assigned to logic may easily be seen to depend, not on what is apparent in the argument, namely, comparison of the sciences with one another, but on what lies implicit in the background, the philosophic conception of the nature of scientific knowledge in general. Without reference to the ultimate philosophic view, no definite content could be assigned to logic, and it would remain impossible to distinguish logic from the sciences in detail.²

3. Thus the various attempts to define the province and functions of logic from general classification of the sciences, to define, in short, by the method of division, yield no satisfactory answer, and refer ultimately to the philosophic view on which classification and division must be based. A similar result becomes apparent when we consider the various descriptions of logic that have been presented as following from more precise and accurate determination of the essential features of logical analysis and method.

"The philosophical deduction or construction of the notion of logic presupposes a comprehensive and well-grounded view, whether of the nature and mode of operation of the human mind, a definite part of which falls under logical treatment, or of the problems and objects of philosophy in general, from among which in due order may be distinguished the particular problem of logic."³ The most elementary distinctions, by means of which, in the ordinary exposition of logic, progress is effected towards an accurate determination of the province of the science, not only refer to some such ultimate philosophic view, but lead to the most diverse results, according to the peculiarities of the views on which they are based. Of these elementary distinctions the following are at once the more usual and the more important,—the distinction between the province of logic and the province of the special sciences, as that between general and special; the distinction between

natural growth of knowledge, with its natural laws, and the normal procedure whereby grounded knowledge is obtained, with its normal or regulative principles; the distinction between knowledge as a whole and its several parts, immediate and mediata, with restriction of logic to the treatment of all or portion of mediata knowledge; the distinction between the constituents of knowledge as on the one hand given from without (in experience), and on the other hand due to the elaborative action of intellect itself. To one or other of these may be traced the common definitions of logic, and a brief consideration of their contents will be sufficient to show that they severally rest upon more or less developed general philosophic doctrines, and that their significance for accurate determination of the field of logic depends not so much on what is explicitly stated in them as on what is implied in the general doctrines from which they have taken their rise.

The distinction of logic from the sciences, as dealing in the abstract with that which is concretely exemplified in each of them, is certainly a first step in the process of determination about which there can be little or no doubt. But if the distinction remains vague, it is not sufficient to differentiate logic from many other disciplines, philosophical or philological, and if it be made more precise, the new characteristics will be found to involve some special view as to what constitutes the common feature in the sciences, and to vary with the possible varieties of view. As a rule, too, the added characteristics do not serve by themselves to mark off logical treatment as an independent kind of investigation. They are most frequently obtained by a general survey of scientific procedure. Thus it may be said that in all sciences there are implied clearly defined notions, general statements or judgments, and methodical proofs; logic therefore, as the theory of the general element in science, will appear as the treatment of notions, judgments, and proofs generally, or in the abstract. If so, then, unless some implied principle further determine the course of procedure, logic would be regarded as a merely descriptive account of the parts making up scientific knowledge, and it would be not only impossible to assign to it an independent position, but hard to discriminate it from psychology, which likewise deals with the parts of knowledge. If it be understood, however, or explicitly stated, that in all scientific knowledge there is community of method, resting on common principles or laws of knowledge as such, than clearly not only the province of logic, as now made identical with the treatment of the essence of knowledge, but the special nature of the theorems making up the body of logic, must depend upon the general conception of knowledge with which the thinker starts. In the view of logic taken, e.g., by Mill, the fundamental idea is that of *evidence*, under which must be included all the grounds for any judgment not resting on immediate perception. So far as verbal statement is concerned, the adoption of this as the root idea would not distinguish in any special way the treatment of logical problems resting on it, but in fact each problem is dealt with in accordance with the particular theory of what, from the nature of human knowledge, constitutes evidence. Logic thus involves, or in truth becomes, a theory of knowledge, and in the end, for general spirit and details of doctrine, refers to an ultimate philosophic view. There seems no escape from this conclusion. Start as we may, with popular, current distinctions, no sooner do logical problems present themselves than it becomes apparent that, for adequate treatment of them, reference to the principles of ultimate philosophy is requisite, and logic, as the systematic handling of such problems, ceases to be an independent discipline, and becomes a subordinate special branch of general philosophy.

The attempt to avoid this conclusion must of necessity

¹ It is to be acknowledged that most of the writers on logic who emphasize the connexion of psychology with logic introduce distinctions equivalent to the remarks above made, but the grounds for such distinctions and the conclusions to be deduced from them are not generally brought into clear light.

² See, for a clear statement of this impossibility, Comte, *Philos. Positive*, i. 34, 35. Definitions of logic as theory of method, which are based on general philosophic views (e.g., the definition by Sigwart, *Logic*, i. § 1), stand on a different footing, and are to be examined on different principles.

³ Twiss, *Die Logik, insbesondere die Analytik* (1825), p. 2.

take form in some discrimination of logic from other varieties which may with it be classed under philosophy in general, and such discrimination is usually effected by laying stress on one or other of the following characteristics.

(1) In the whole process of knowledge, it may be said, we are able to distinguish and to regard in isolation the methods according to which, from a combination of various elements, cognition of things grows up, and the laws according to which these elements must be ordered, if our subjective consciousness is to represent accurately and faithfully the relations of things. The laws of knowledge, there being understood by knowledge the whole sum of mental determinations in and through which the world of external and internal experience is realized for us, are of two distinct kinds, natural and normal. For the treatment of the natural laws the most appropriate title is psychology; for that of the normal or regulative laws the title logic is peculiarly appropriate. By the one science knowledge is regarded in its relation to the subjective consciousness, as so much of what enters into and constitutes the world of inner experience; by the other knowledge is regarded in its relation to truth, to the objective system, as the means whereby, for theoretical or practical purposes, an orderly and verifiable conception of this system is realized. A definite place seems thus secured for logic, but, if one may judge merely from the various attempts to expound the body of logical doctrines from this point of view, the characteristic feature is not yet sufficient to determine the boundaries of the science or the specific nature of its problems. In fact, the feature selected might be accepted as the distinguishing mark of logical-science by writers who would include under that common title the most diverse matters, and who would differ fundamentally in respect to the treatment of isolated problems. The metaphysical logic of Hegel, the empirical logic of Mill, the formal logic of Kant, might all claim to be developments of this one view of the essence of logic. So wide a divergence is clear evidence that the criterion selected, though possibly accurate, is not sufficiently specific, and that the interpretation of it, which in truth determines for each the nature and boundaries of the science, depends upon the view taken respecting knowledge as a whole in its relation to the objective order of experience, respecting the import of the so-called normal laws, and respecting the subjective elements supposed to constitute knowledge.

On all sides this particular definition of logic is beset with difficulties, which it cannot afford to dismiss by means of the simple demand that knowledge shall be accepted as somehow given. For, apart altogether from the danger that under so wide a term as knowledge many differences may be accommodated, it, then becomes impossible to do, more than treat in a quasi-empirical fashion mental facts, the nature and peculiarities of which are to be learned from some external source. In the later, more detailed examination of the view of logic here briefly described, it will be pointed out that the usual formula by which the several logical notions are introduced, viz., that their nature as mental facts is dealt with in psychology, from which logic borrows, is in fact much more than a formula. The logical peculiarities will be found to rest mainly upon the psychological characteristics as borrowed, while it is evident that no substantive, independent existence can be vindicated for a doctrine, the succession of whose parts, and their essential nature, are given externally.

(2) Some of the perplexities that arise when logic is treated as the theory of the normal laws of knowledge may be obviated by the current distinction between immediate and mediate knowledge. The normal laws of knowledge might be said to apply solely to the process of mediate cognition, and their final aim would be defined as harmony

between mediate knowledge and immediate experience. But it is difficult to distinguish with perfect accuracy between the two kinds of knowledge in question; it is impossible that the treatment of the logical problem should not depend entirely on the view taken as to the nature of that which differentiates mediate from immediate knowledge. Whether we express this as thought or as belief, its nature then becomes the all-important factor in determining the course of logical treatment, and further progress will manifest divergencies according as stress is laid on the subjective characteristics of thought, the laws to which, from its essential nature, all its products must conform, or on the limitations imposed by principles which have reference to the most general relations of the things thought about. In the one case a formal logic, of the type commonly known as the Kantian, would be developed, in the other either an empirical logic, like that of Mill, wherein the nature of notions, propositions, and reasonings is considered from the point of view of the empirical conception of experience, or a transcendental logic, like that involved in the *Critique of Pure Reason*, or a metaphysical logic, like that of Hegel, or a mixed doctrine, like that of Trendelenburg, Lotze, and Ueberweg. In short, the general philosophic view of thought is that upon which the character of logic as a science rests.

(3) There has above appeared, incidentally, one of the most current methods of solving the logical problem, by procedure from the distinction between that which is given to the mind in knowledge, and that which is supplied by the mind itself. No distinction seems more ample; none is in reality more complex. The opposition on which, in its popular acceptance, it rests is that between the individual concrete thinking subject and the world of objective facts, existing, as it were, to be cognized. The full significance of such an opposition, the forms in which it presents itself in conscious experience, the qualifications which must be introduced into the statement of it that it may have even a semblance of reality,—these are problems not solved by a simple reference to the distinction as existing. It may well be held that knowledge is, for the individual, the mode (or one of the modes) in which his relation to the universe of fact is subjectively seized, but it is not therefore rendered possible to effect an accurate and mechanical separation of knowledge into its matter and form. Even on lower grounds it may be held that by the employment of this criterion little or no light is thrown upon the logical question. For no determination is supplied by it of the universal characteristic of form as opposed to matter in knowledge, and a comparison of various expositions will show the most startling diversity of view respecting the nature and boundaries of the formal element in knowledge. It is of course true that in one sense any scientific treatment of knowledge is formal. Our analysis extends only to the general or abstract aspect of cognition, not to its actual details. But we are not, on that account, dealing with the form of knowledge. So soon as it is attempted to define more accurately what shall be understood by form then it is found that various views of logic arise, corresponding to the variety of principles supposed to be applied in the treatment of form. Thus the stricter followers of the Kantian logical idea, e.g., Manass and Spalding, recognize, as sole principles which can be said to be involved universally in the action of thought, the laws of identity, non-contradiction, and excluded middle, and in their hands logic becomes merely the systematic statement of these laws, and the exposition of the conditions which they impose upon notions, judgments, and reasonings. Analytical consistency, i.e., absence of contradiction, is on this view the one aspect of knowledge which is susceptible of logical treatment. On the other hand, the idea of a contribution furnished by the

mind itself to knowledge may lead to a more concrete and yet not less exact system of the forms of knowledge, if there be taken into account the real character of the operation by which such contribution is made. Thus in the logic of Uriol, from the view of thought as essentially the distinguishing faculty, by which definiteness is given to the elements entering into knowledge, there follows not simply an iteration of the principle that thought must not contradict itself, but a systematic evolution of the fundamental relations involved in the action of thought, in which the more specifically logical products, the notion, judgment, and reasoning, have a determinate place assigned to them.

Not only, then, may quite distinct provinces be assigned to logic by thinkers who start with the same idea of thought as contributing to knowledge, but, as may well be imagined, the treatment of special logical problems presents a most bewildering variety. The nature of judgment, the principle of reasoning, the characteristics of thought which is in accordance with logical rules, will be viewed differently according to the special interpretation put upon the functions of the subjective factor in knowledge. Here again we find that the really influential fact in the determination of the province and method of logical sciences is a general philosophic conception of knowledge or thought.¹

4 There remains yet one method by which a clear and sufficient definition of the province and function of logic may be attainable. It may be that the separation of logic from other philosophic disciplines has come about historically, and that the assignment to logic of a special body of problems and a special kind of treatment is due to the accidents of its development. We might therefore hope to gain from a comparative survey of the field of logic, as that has been historically marked out, some definite view not only respecting the specific problems of logical theory, but also regarding the grounds for the isolated treatment of them. That in the history of logic there should be found a certain continuity of doctrine and development may, however, be compatible with entire absence of a common body of received logical matter, and the result of an historical research may be little more than a statement of distinct conceptions regarding the nature and province of the science, leading to the inclusion of very distinct materials within its scope. It requires but a superficial investigation of that which at various intervals has presented itself as logical theory to arrive at the conclusion that the differences in general spirit and in the mass of details far outweigh any agreement as to a few detached doctrines and technical symbols. If the survey were limited even to the period preceding the attempts at radical reformation of philosophy in general, and of logic as included therein, to the period in which the Aristotelian doctrines, as they may be called, formed the common basis of logical treatment, we should be able to detect differences of such a kind as to indicate radically distinct fundamental views. The scholastic logic, which, even by itself, cannot be regarded as one theory with unimportant modifications, is most falsely described as Aristotelian. The technical terminology, the general idea and plan, and some of the formal details are certainly due to the Aristotelian analysis of reasoned knowledge, but in spirit, in ruling principles, and in the mass of details the method of the scholastic logic is alien to that of Aristotle. It will be shown later that the Aristotelian analysis is saturated with the notions, and aims of the Aristotelian metaphysics and general theory of knowledge, and that on this account alone, apart from

the introduction of many foreign ingredients, from Stoic, Arab, and Byzantine sources, into the scholastic system, an important difference must subsist between the original doctrine and that which presents itself as but its historical development. Even more radical is the divergence of modern logic from the Aristotelian ideal and method. The thinker who claimed for logic a special pre-eminence among sciences because "since Aristotle it has not had to retrace a single step, . . . and to the present day has not been able to make one step in advance,"² has himself, in his general modification of all philosophy, placed logic on so new a basis that the only point of connexion retained by it in his system with the Aristotelian may be not unfairly described as the community of subject. Both deal in some way with the principles and methods of human thinking, but as their general views of the constitution of thought are diverse, little agreement is to be found in the special treatment of its logical aspect. So when a later writer prefaces his examination of logical principles with the declaration that "logic is common ground on which the partisans of Hartley and of Reid, of Locke and of Kant, may meet and join hands,"³ we are not unprepared for the result that, with a few unimportant exceptions, his views of logical principle coincide with those of no recognized predecessor in the same field, diverge widely from either the currently received or the genuine Aristotelian doctrines, and lead to a totally new distribution, in mass and detail, of the body of logical theorems and discussions. Such divergence is, indeed, most intelligible. If one reflects on the significance which would be attached in any one of these logical systems, of Aristotle, of Kant, of Mill, to the *universal* or universalizing element of thought, and on the fact that such universal must manifest itself as the characteristic feature in all the important products of thinking, the notion, the judgment, the syllogism, the conclusion is inevitable that difference of view in respect to the essence must make itself felt in difference of treatment of details. The ultimate aim of proof, and the general nature of the methods of proof, must appear differently according as the accepted ground is the Aristotelian conception of nature and thought, the Kantian theory of cognition, or subjective empiricism.

If, adopting a simpler method, one were to inspect a fair proportion of the more extensive recent works on logic, the conclusion drawn would be probably the same,—that, while the matters treated show a slight similarity, no more than would naturally result from the fact that thought is the subject analysed, the diversity in mode of treatment is so great that it would be impossible to select by comparison and criticism a certain body of theorems and methods, and assign to them the title of logic. That such works as those of Trendelenburg, Ueberweg, Uriol, Lotze, Sigwart, Wundt, Bargmann, Schuppe, De Morgan, Boole, Jevons, and these are but a selection from the most recent, treat of notions, judgments, and methods of reasoning, gives to them indeed a certain common character; but what other feature do they possess in common? In tone, in method, in aim, in fundamental principles, in extent of field, they diverge so widely as to appear, not so many different expositions of the same science, but so many different sciences. In short, looking to the chaotic state of logical text-books at the present time, one would be inclined to say that there does not exist anywhere a recognized, currently received body of speculations to which the title logic can be unambiguously assigned, and that we must therefore resign the hope of attaining by any empirical consideration of the received doctrine a precise determination of the nature and limits of logical theory.

¹ In Rosenkranz, *Die Modificationen der Logik abgeleitet aus dem Begriff des Denkens* (1848), a similar conclusion is illustrated by an elaborate classification of possible modifications of the view of logic. Compare also Brandes, *Die Logik in ihrem Verhältnisse zur Philosophie geschichtlich betrachtet* (1856).

³ Mill, *System of Logic*, i. p. 18.

5. In order to make clear the reasons for this astonishing diversity of opinion regarding the province and method of logic, and so make some advance towards a solution of what may well be called the logical problem, it seems necessary to consider some of the leading conceptions of logic, with such reference to details as will suffice to show how difference of fundamental view determines the treatment of special logical problems. In this consideration the order must be historical rather than systematic. Not, indeed, that it is useful, nor is it proposed, to present an historical account of philosophy at large, or even of logic in particular, our purpose is merely to disentangle and bring clearly forward the nature of the principles respecting logical theory which have served as basis for the most characteristic logical systems. Such an inquiry will not only assist in explaining the divergencies of logical systems, but throw light upon the essence of logic itself.¹

In this historical-critical survey, the first section must naturally be devoted to a consideration of the Aristotelian logic. The records of Oriental attempts at analysis of the procedure of thought may, for our present purpose, be disregarded.²

The Aristotelian Logic.

6. In a remarkable passage at the close of the tract called by us the *Sophistical Refutations*, Aristotle claims for himself distinct originality in the conception of subjecting to analysis the forms or types of argument. "The system I have expounded had not been partially, though imperfectly, elaborated by others; its very foundations had to be laid. The teachers of rhetoric inherited many principles that had long been ascertained; dialectic had absolutely no traditional doctrines. Our researches were long, tentative, and troublesome. If, then, starting from nothing, it bears a comparison with others that have been developed by a mass of labour in successive generations, candid criticism will be readier to commend it for the degree of completeness to which it has attained than to find fault with it for falling short of perfection."³ Although the specific reference in this passage is to the analysis of dialectical argument contained in the *Topics*, the same claim might with justice have been made in regard to the more extensive analysis of the forms of reasoning in general which makes up the substance of the other books of the *Organon*. There had been, prior to Aristotle, much discussion of problems that would under any view be included under the head of logic, but no systematic attempt had been made to analyse knowledge as a whole in its formal aspect, to throw under general heads or classes the types of reasoning, whether dialectical or scientific, and to exhibit the general relations in which the elements of all reasoning stand to one another. After Aristotle, it became possible to refer all such discussions to a common head, and to view them as component parts of one systematic doctrine. In a peculiar sense, then, Aristotle may be described as the founder of logical science.

The precise nature of the inquiries falling within the scope of the Aristotelian logic may receive some preliminary explanation supplementary to that which can only be given by a careful study of the chief theorems of the system. If there be taken into account (a) the advance towards a theory of logical method contained in the speculations of earlier Greek thinkers, (b) the classification of philosophic discipline which underlies the body of Aristotle's writings, and (c) the general conception of the matter of logical analysis which may be deduced from any special or incidental treatment of the question in Aristotle. Of these in order.

7. (a) Logical discussions prior to Aristotle.

The inquiries which find a place in the Aristotelian logic are all, in a large sense, problems of the theory of knowledge. They arise, therefore, only in connexion with critical reflection on the nature, grounds, and method of knowledge. The earliest forms of Greek speculation, turning rather upon explanation of natural fact, being in essence attempts to reduce the multiplicity of known fact to unity of principle, contain, as a consequence, problems of a metaphysical character, which might involve problems of strictly logical analysis which may be deduced from any special or incidental treatment of the question in Aristotle. Of these in order.

¹ For a notice of works on the history of logic, see note A. p. 802.

² For notices of some of the more developed systems of Oriental logic, see note B. p. 802.

³ The above translation, which is somewhat free, is taken from Mr Porter's edition of the *Sophistical Elements*, p. 95.

history of philosophic speculation. In the first period of Greek speculation, the problem presented itself in its simplest, most direct aspect, and, after a few rough attempts at a quasi-physical explanation of the genesis of many out of one, these came forward, as reasoned, ultimate solutions, the Eleatic doctrine that one unity has laid being the Heraclitic counter-doctrine that only in change, in the many, is truth to be found, and the Pythagorean notion of number, harmony, as containing in abstract the union of the opposites, one and many. No one of these philosophic treatments can be said to contain specifically logical elements, but they raise questions of a logical kind, and, especially in the records of the Eleatic view, one can trace a close approximation to the critical reflection which marks the transition to a new order of ideas. Results which in these systems are stated with metaphysical reference only, reappear with new aspect among the sophists and the Socratic schools. The transition stage, indeed, partly aided by the atomic separation of objects far from a subjective sense experience, is mainly the effect of the sophistic and Socratic teaching. Socrates and the sophists have this in common that both treat the fundamental problem of philosophy as it had been handed down with special reference to the subjective experience of the individual. In the teaching of the sophists generally it is to be discerned the opposition between subjective reflection and objective fact, in that of Protagoras and Gorgias in particular there appear as problems of the theory of knowledge difficulties for the older metaphysics of Heraclitus and the Eleatics respectively. The Heraclitic principle of change is the general foundation for the doctrine that the momentary perception is the only fact of cognition, and upon it may be based the conclusion that all truth is relative to the individual state of the individual subject, and that judgment, as a mode of expressing truth, is a contradiction in itself. Thus the extremes Heraclitism, as a unity, rejected the proposition, or combination of words, as expressing a unity and permanence not to be found in things, and reduced speech to the symbolism of pointing with the finger. Less developed but not less clear is the connexion between the brief sceptical theses of Gorgias and the Eleatic doctrine of unity. As knowledge was impossible on the Heraclitic view, since it implied a synthesis not discoverable amidst incessant change, so Gorgias' knowledge was impossible, since in the synthesis was involved an element of difference, multiplicity, not reconcilable with the all-embracing unity of things. It is evident from the treatment of such views in Plato and in Aristotle, how many of the illustrations used in support of the general theses depended for their apparent strength on neglect of some of the elementary conditions of thought, and how inevitably reflection upon those difficulties led to the construction of a theory of thought. The first outlines of such a theory are to be found in the Socratic principle of the notion (or concept, as we may call it, for the notion as viewed by Socrates is certainly the concrete class notion, the ample result of generalization and abstraction), and to Socrates is assigned by Aristotle the first statement of two important logical processes—induction, or the collection of particulars from which by critical comparison a generalized result might be drawn, and definition, or the explicit statement of the general elements disclosed by critical comparison of instances. In the Socratic teaching, so far as records go, no explicit reference was made to the problems in connexion with which those processes are of greatest significance, but in the lesser Socratic schools on the one hand, and in Plato on the other, we find the new principle either brought to bear upon the old difficulties, or developed into a comprehensive method.

The Socratic concept contains in itself the union of one and many, but it is in nature subjective; it is a mode of knowledge. If, then, it be regarded as only subjective, the old difficulties reappear. How is it possible to reconcile, even in thought, an opposition so fundamental as that between unity and diversity? But there yet is a like irreconcilable opposition between the subjective counterparts of these objective relations, between the individual notion, the atom of knowledge, and the proposition or definition. How, indeed, can there be a combination in thought of that which is in essence irreconcilable? Wherever we take these questions, which draw mainly for theory of knowledge on the Heraclitic Pythagorean sources, or Antisthenes, who leans towards the Eleatic, or the Megarics, who also, in accordance with the Eleatic thoughts, devoted chief attention to the polemical aspect of the theory, we find a set of problems appearing, the solution of which impetively called for a theory of knowledge as the combination of one and many. Perhaps the most interesting of these early thinkers, so far as the history of logic is concerned, is Antisthenes, whose extreme nominalism presents the most curious analogies to some recent logical work.⁴ According to Antisthenes, the world of cog-

⁴ *Metaph.*, 1078b, 27-28.

⁵ On Antisthenes, see the third part of the *Thaïs*, which appears, beyond doubt, to refer to him (comp. Peipers, *Untersuchungen über das System Platons*, 1874, pp. 124-48), and Aristotle, *Metaphysics*, 1028a, 32; 1049b, 24; *Topics*, 1048b, 21.

simplest fact consists of combinations of elementary parts (*πρώτα*). These *πρώτα* appear in cognition as irreducible elements denoted by the simplest elements of speech, names. The name is the mark for the sense-impression by which each *πρώτον* is communicated to us, for they are only known by sense, and are strictly individual. A composite thing is known through the combination of names of its parts, and such a combination (*σύνθεσις*) is a proposition or definition (*λόγος*). Each thing has its specific *λόγος* (*οικείος λόγος*), and a judgment is merely the expression of this. There is therefore no distinction of subject and predicate possible; even identical propositions, the only possible forms of this theory, are mere repetitions of the complex name. Predication is either impossible or reduces itself to naming in the predicate what is named in the subject. It is the simple result of so consistent a nominalism that all truth is salutary or relative; there is no possibility of contradiction, not even of one's self.

The theory of Anaximenes, strange as it may at first sight appear, rested on certain metaphysical difficulties, which lie at the root of all the perplexity regarding the import of propositions, and it is not too much to say that these difficulties were kept continually in mind by Plato and Aristotle in their several attempts to explain the nature of knowledge. Both thinkers find themselves confronted with the ultimate question, What is the ground of unity in things known, and in what way does thought unite the detached attributes of things into a subjective whole? What is the nature of the unity which binds things, themselves in a sense unites, into classes or wholes, and how does it act in the judgment subject and predicate are, in a sense, set at one?

In Plato, for whom the solution was found in the participation in or immanence of ideas by things, we find more distinctly conceived the series of logical processes involved obscurely in the Socratic method. So far as positive statements regarding the ideas can carry one, it may be said that in essence these processes concern only the formation of or deduction from the concrete universal concept or general notion. The ideas, in the Platonic system, at least in reference to the thought which apprehends them, resemble most closely class notions. A deeper analysis often appears to attach to the relative processes of *induction*, whereby the resemblance of things, the idea in them, is disclosed, *definition*, whereby the content of the idea is made explicit, and *division*, whereby the external connection of ideas with one another, their system, is deduced, but such significance attaches to the merely metaphysical aspects of the theory, and had no particular bearing on the Aristotelian treatment of the same problems. Not much is given in Plato towards a theory of the proposition, though sometimes an analysis of its elements is sketched, and the method of division could yield only a few of the types of deductive reasoning. But, over and above these more definite contributions towards the construction of a theory of knowledge, there are general aspects of the Platonic work of not secondary importance for the Aristotelian logic. In Plato the fundamental differences of earlier philosophy views appear in a new phase, and are elevated to a higher stage. Sophistic method is analysed, not as in forms actually existing, but in its essential features, and the opposition between sophist and philosopher is viewed as the opposition between opinion and knowledge. Heraclite principle of change and Eleatic doctrine of unity are resolved into the more comprehensive opposition of the universal and the particular, while hints of an ultimate solution, of a universal which is at once and *per se* particular, are not wanting. The Socratic method of thought appears as that by which alone a solution of philosophic difficulties is to be obtained, and the consideration of thought in its relation to facts is marked out for special investigation. A deeper view of thought was thus made at once possible and necessary.

(8) Much, then, had been effected by Aristotle's predecessors in the way of preparing a definite body of problems and a method of dealing with them, problems and method which might fairly be said to belong to a theory of knowledge as such, and in the occasional references in the *Organon* to opinions of contemporaries it is evident that many isolated attempts at solution of such questions were being carried on. In Aristotle we find a systematic examination of many of these problems, but it is left by him doubtful what place in the general scheme of philosophy science should be assigned to the distribution into physics, mathematics, and first philosophy, or the wider classification of doctrines as poetic, practical, or theoretical, in no way enables us to class logic or the body of speculations making up the *Organon*. That the forms of proof analysed in these writings are of universal scope is unambiguously declared; that the first principles assumed in all proof are dealt with in first philosophy is also made clear; but the relations between the two doctrines so reciprocally related cannot be determined from any statement made by Aristotle himself. That he should have regarded the inquiries of the analysis as propaedeutic in character and should have held that those who assume to discuss problems of first philosophy ought to have made themselves acquainted with the general theory of proof is intelligible, and more than this significance cannot, we think, be assigned to the passage in the *Metaphysics*, on the ground of which the logical

inquiries have been classed as the general, common introduction to the whole system.¹ For the close connexion between the analytical researches of the *Organon* and the inquiry into essence or being as such forbids us to accept, in any strict sense, a separation of these as forming distinct and independent sciences. To metaphysics is assigned the consideration of the principles of proof, and the kind of inquiry making up first philosophy is described by Aristotle in a fashion which assimilates it most closely to the researches of the analytics. That which is left undecided by the Aristotelian classification is the relation of the logical inquiries to the organic whole of which first philosophy is the main or sole part. To obtain any fresh light we must turn to the consideration of indications supplied by Aristotle as to the nature of the inquiries grouped under the head *Analytics*.

9 (4) Such indications are unfortunately most scanty. As we probably have not the *Metaphysics* in its full extent actual or contemplated, the want of a clear separation between the inquiries belonging specially to first philosophy and those appropriate to the analytical researches may be due in part to the deficiency of our materials. There are, however, two lines of separation discernible, from which some useful inferences may be drawn. What we call the logic of Aristotle, *i. e.*, the treatise making up the *Organon* is roughly divisible into three parts.—(1) the formal analysis of syllogism and its allied types of reasoning, with the more particular discussion of the elementary parts of reasoning: the proposition; (2) the theory of scientific proof and deduction (apodictic); (3) the theory of probable arguments, or of reasoning based on currently received opinions and leading to conclusions more or less probable (dialectic). Certainly for Aristotle there was no such distinction between the first and the remaining two parts as would in any way correspond to the modern separation of general or formal logic from the logic of knowledge, or mental logic; the three parts in conjunction make up one body of doctrine. Now dialectic is very specially indicated as being of a formal character, *i. e.*, as dealing with no special matter, but with *κατά*, opinions, or types of opinions common to all sciences.² Apodictic, we may assume, is in like manner a formal study of which constructs knowledge rests, so-called, the nature of the principles on which knowledge rests, the special marks distinguishing it, and the method by which knowledge is framed. But in every body of doctrine we may distinguish, according to Aristotle, three things,—the genus or *γένος* of which we deal, with which the demonstration converges, the essential or fundamental attributes, qualities of these objects, which are to be demonstrated of them, and, thirdly, certain common axioms or principles of demonstration, not themselves demonstrable, and not entering as integral parts into the demonstration, but lying in the background as the security for the security of the argument employing them. Can anything corresponding to these three facts be discovered, if we assume for the moment, what certainly is not explicitly stated by Aristotle, that analysis constitutes a special body of doctrine? The genus or class about which the doctrine is concerned can only be reasoning itself, either as apodictic or dialectic, and the latter for a special reason may be left out of account, *ἀπεὸς*, then, is the matter concerning which the doctrine is put forward. But *ἀπεὸς* is a form of knowledge, that is to say, is subjective. The properties, therefore, of apodictic science can only be made clear if we consider on the one hand the objective counterparts of necessity and universality in thought, and on the other hand the nature of universality and necessity of thought itself. The common principles or axioms, finally, can only be such presuppositions as are made in apodictic or reasoning generally concerning thought in its relation to fact, as grasping or apprehending reality. The consideration of such axioms, if it has been already seen, pertains to first philosophy. Analytics then would appear as an independent doctrine, holding of first philosophy on the one hand, both in regard of the common axioms and in regard of the attributes of being, by which it is as possible object of science, and on the other hand referring to the subjective treatment of thought, whether in relation to principles or to fact generally.

A very similar result may be attained if we follow out a line of distinction indicated in more than one portion of the *Metaphysics*.³ Separating the modes in which being is spoken of into four—(1) *τὸ βεβαιὸν καὶ ἀμεταβάτον*; (2) *τὸ βεβαιὸν καὶ μεταβάτον*; (3) *τὸ ἄν καὶ ἄν καὶ ἐκ φύσεως τὸ ἐκ ἀνάγκης*; (4) *τὸ βεβαιὸν καὶ ἀμεταβάτον*—Aristotle excludes the second from the special researches peculiar to first philosophy, the study of being as being, but neither excludes it from general consideration in metaphysics as a whole,

¹ *Metaph.* vi. 1026b, 9. See Zeller, *Phil.* 2. d. Gr. 1. 2 (86 ed.), p. 194, n.; Bannov, *De Definit.* Not. 46, 47; Schwartz, *Comment. sup. Metaph.* vi. 1021; and, contra, Prantl, *Gesch. d. Logik*, I. 187. Prantl maintains the view that Aristotle intends to indicate the uses occupied by the analysis in his general scheme of philosophy.
² On Aristotle's use of the term *κατά* and its allies, see [its addition to White, *Phil. in Organ.*, p. 345-360] Schwartz, *Comment. sup. Metaph.* vi. 17, p. 48-51.
³ See *Anal. Post.* I. 1; *Ethic.*, I. 1, and in many passages. Cf. Heyder, *Method.* d. *Anal.*, p. 148.

⁴ *Metaph.* vi. 4, v. 20, 12. Cf. Schwieger, *Comment.* vi. 241, v. 29 sq., 106; and Brentano, *Reinhold des Aristoteles nach Arist.*, 21 sq.

nor handles it at length, deferring it either for more detailed treatment. A comparatively clear account, however, of what is understood by him under the idea of being as truth and non-being as falsity may be extracted from the various passages referred to, and little doubt can remain that being so regarded is in a peculiar sense the matter of analytical (i.e., logical) researches.

Being as truth and non-being as falsity refer to and rest upon combination and division of the elementary parts of thought. For truth and falsity have no significance when applied to things, but only to the connexion of thought which is dominated by the one principle of non-contradiction. Nay, thinking has not even immediate and direct reference to being as such, but only to being as the existent, as qualified, or quantified, or modified in some other way (i.e., according to the categories), and it is in its very essence the conjunction or unifying of elements. What cannot be conjoined, as, e.g., the notions of elementary ideas themselves, are not either true or false, and are not matters of thought. Thought thus moves in a definite sphere, that of the combinable or separable, the correspondence of concepts with real relations, and has its limits on the one hand in the elementary data apprehended by intellect (*noûs*—reason), and on the other hand in the infinite sea of particular, accidental qualifications of things (*συμβεβηκός*).¹ The possibility of contradictory assertions (for true and false judgments together make up this contradiction, *ἐκ τῶν ἀληθῶν καὶ ψευδῶν ἀποφάντων*) is the distinguishing mark of thought. Now it is this very possibility that lies at the root of all the analytical researches. Not, indeed, that one can assume for Aristotle a view which has appeared in later logical works, that all forms of logical reasoning are to be deduced from the principle of contradiction. Quite the reverse. The common axioms underlie all processes of proof, direct or indirect, but they do not enter into or form part of proof. Nothing can be deduced from them, but their authority can be appealed to against any one who refuses to allow a conclusion reached by a correct syllogism from true premisses.² (The nerve of logical proof would thus lie in the distinctive proposition; either this conclusion is to be granted or the principle of contradiction is denied.) Now the analytical researches are in especial the treatment of combination and separation in thought, or even the syllogism may be regarded as a special instance of combination and separation in the exposition of the forms of combination and separation we shall find a complete system extending from the unproved principles and exhibiting the methods according to which thought proceeds towards the determination of the essential properties of things or the discrimination under which things are the transitory and accidental attributes may be advantageously classed.

So far then as one can judge, the matter of Aristotle's analytical researches may be expressed as the concrete nature of thought, characterized by its fundamental attribute, the possibility of contradiction, contradiction, contradiction, contradiction, and having as its end the realization of systematic knowledge, i.e., the adequate subjective interpretation of being.

10. The indication that the analyses have to do with being as conceived by thought, conducted under the general axiom of non-contradiction and expressed in language, requires to be filled up by a more detailed treatment of the Aristotelian theory of thought in relation to being. Upon the characteristics assigned to thought or knowledge in this special relation, must depend the general nature of the Aristotelian logic, the determination of the scope of logical treatment, and the essence of logical method. For from a quite similar starting-point regarding the province within which logic moves totally diverse conclusions might be drawn respecting the precise function of logical method. One might have either a formal doctrine or *techné*, or a real methodology, either an attempt to evolve logical principles from the axiom of contradiction, or a development of the laws according to which thought necessarily setting under the aid axiom, proceeds towards the construction of knowledge. The history of logic clearly shows how differently the matter of the analysis may be viewed. For one of the possible conclusions, that logic is a techné or quasi-mathematical exposition of formal relations, has been accepted as the undoubted result of Aristotle's teaching, and has so prevailed as to make itself the current conception.³ The other, the view of logic as theory of the method of scientific thought, has been cast entirely into the background, so far as logical doctrines are concerned, and, if allowed at all, has been regarded as foundation for a species of applied logic, an appendix to the other.

11. Not much aid is afforded directly by any classification or division of the books now collected together as the *Organon*. As above noted, the *Prior* and *Posterior Analytics* with the *Topics* form one connected whole, while the *Categories* and the *De Interpretatione* stand apart as isolated treatments of special problems, not organically or necessarily part of researches. The genuineness of both these treatises has been doubted (see ARISTOTELIS, vol. II, p. 514), and it is not improbable that both are redactions of Aristotelian

material, perhaps drawing from other lost writings of Aristotle, perhaps based on oral teaching, by some Aristotelian scholar. A summary view of the contents of the other books will be found at vol. II, p. 516.

12. The logical researches as a whole manifest a strong unity, and at the same time refer to one fundamental opposition, that between *apodictic* and *dialectic* reasoning.⁴

The opposition between apodictic and dialectic is in the Aristotelian system the development of that which had already played so important a part in Plato and Socrates, the distinction between *science* and *opinion*. Knowledge in the strict sense had there presented itself as the generalized notion referring to being in its very essence, and resting on thought or reason. Opinion is the quasi-knowledge of the particular, referring to that which is not being but only accident, and resting on senses or imagination. In the Platonic method, this distinction had come forward as the underlying basis for the opposition of philosophy and sophistical rhetoric; in Aristotle a much more precise formulation is given of the characteristics of the two opposed forms of thought, and the connexion between opinion or dialectic and rhetoric-sophistical discussion is made more concrete and profound. Dialectic, with Aristotle, is the system resulting from the attempt to reduce to rule or generalize modes of argument which rest upon current received doctrines as principles, which move within the region of interests about which current opinions *pro* and *con* are to be found, and which terminate not in the decisive solution of a problem but in clearing the way for a more profound research or at least in the establishment of a *modus vivendi* against an opponent. Dialectic, then, has no special province; it deals with *κείν* or *ἐκείν*, and its methods are perfectly general. On the one hand, as being the application of reasoning, it refers to and employs the specific types of reasoning, syllogism and induction; on the other hand, as being applied to matters of opinion, and borrowing its principles from current floating data about matters of common interest, the type of reasoning tend in it to assume special forms resembling those employed in rhetoric (which is a kind of offshoot from dialectic—the application of dialectic to political principles). The province of dialectic being thus essentially vague, the matters about which dialectic reasoning is concerned being of the most fluctuating character, there must be, for Aristotle, the greatest difficulty in determining, *per se* and apart from the opposition to apodictic, what is the character of dialectic syllogism and induction. Nor can it be said that the interpreter of Aristotle has as any easy task in the endeavour to disentangle the frequently dual actual reasoning and in what way the forms which are assumed to be common both to apodictic and dialectic come to have any application to the fluctuating mass of current opinions. It is comparatively simple to say apodictic and dialectic differ in this, that the one rests on principles essential, necessary, seen to be true, while the other proceeds from data which are merely received as credible and as containing probable, received opinions on a subject about which there may be difference of view; and it may be added that in the one we reach conclusions which are essential, in which the predicate is necessarily and universally true of the subject, while in the other the conclusion remains like the data, credible merely, and is, at best, only one of the probable answers to a question. But there remains the difficulty, which is certainly not cleared up by any direct statement from Aristotle—of what nature is the syllogistic method that applies to material of this kind and what is the *νέστω* *προβάν* in a dialectic syllogism? There are two possible views—either that the principle of syllogistic inference is purely formal, deducible from the characteristics of thought as either affirming or denying in reference to a particular subject, and therefore capable of application either to probable or to necessary matter, or that the syllogism is explicable only as a form in which knowledge is established and is applicable but, *per se*, as one may express it, to probable matters. Under this second view, that a dialectic syllogism and reality of syllogistic inference would be traced to the correlative peculiarities of human thought and of the nature of the objects of thought, and it would follow that in strictness there is no dialectic syllogism. Such a conclusion at first sight appears to stand in sharp opposition to quite emphatic utterances of Aristotle, in which we are told that the principle of syllogistic inference is the necessary support, for the acts of example, that a dialectic syllogism, when framed, we should readily discern that the link of connexion between data and conclusion, the *νέστω* *προβάν*, as it may be called, does not in fact differ from that involved in the apodictic syllogism. The merely probable character of the data prevents the conclusion

¹ The most important treatments of the principles and details of the Aristotelian logic, which are here drawn upon freely, are (1) *infer* *opinion*, that of Franz (Quint. & Logic, I, pp. 87-94); (2) *infer* *opinion*, that of Franz (Quint. & Logic, I, pp. 87-94); (3) *infer* *opinion*, that of Franz (Quint. & Logic, I, pp. 87-94); (4) *infer* *opinion*, that of Franz (Quint. & Logic, I, pp. 87-94); (5) *infer* *opinion*, that of Franz (Quint. & Logic, I, pp. 87-94); (6) *infer* *opinion*, that of Franz (Quint. & Logic, I, pp. 87-94); (7) *infer* *opinion*, that of Franz (Quint. & Logic, I, pp. 87-94); (8) *infer* *opinion*, that of Franz (Quint. & Logic, I, pp. 87-94); (9) *infer* *opinion*, that of Franz (Quint. & Logic, I, pp. 87-94); (10) *infer* *opinion*, that of Franz (Quint. & Logic, I, pp. 87-94); (11) *infer* *opinion*, that of Franz (Quint. & Logic, I, pp. 87-94); (12) *infer* *opinion*, that of Franz (Quint. & Logic, I, pp. 87-94); (13) *infer* *opinion*, that of Franz (Quint. & Logic, I, pp. 87-94); (14) *infer* *opinion*, that of Franz (Quint. & Logic, I, pp. 87-94); (15) *infer* *opinion*, that of Franz (Quint. & Logic, I, pp. 87-94); (16) *infer* *opinion*, that of Franz (Quint. & Logic, I, pp. 87-94); (17) *infer* *opinion*, that of Franz (Quint. & Logic, I, pp. 87-94); (18) *infer* *opinion*, that of Franz (Quint. & Logic, I, pp. 87-94); (19) *infer* *opinion*, that of Franz (Quint. & Logic, I, pp. 87-94); (20) *infer* *opinion*, that of Franz (Quint. & Logic, I, pp. 87-94); from having a higher value than mere likelihood, but does not affect the chain of inference, which proceeds on assumptions identical with those involved in apodictic. Aristotle is chary of any examples of dialectic syllogism, and indeed, if one considers that all forms of modality are investigated in the general analysis of syllogism, it becomes difficult to see what specially distinguishes dialectic inference. It is not to be denied, however, that the investigation of the grounds for the coexistence of dialectic and apodictic is incomplete in Aristotle, as it confessedly is in Plato

... unless, these can be shown beyond possibility of question that Aristotle does lay down purely formal rules for syllogism, *aletheia* and *episteme* simply from the fundamental axiom of thought—and the evidence on which such a view is based will be examined later—we do not obtain much light from the opposition between dialectic and apodictic. More important results, however, are gained when we consider the Aristotelian doctrine of genuine knowledge, of *arêteis*; for, among the numerous elements that here fall to be noted, some are of quite general import, and apply to the whole process of the formation of knowledge.

13 Apodictic knowledge generally is definable through the special marks of its content. It deals with the universal and necessary, that which is now and always, that which cannot be other than it is, that which is what it is simply through its own nature. It is the expression of the true universal in thought and things, *τὸ καθόλου*. Further, as a method, *ἀποδεικτικὴ* is characterized by the fact that it is a method of proceeding from a connecting link derived, as well as by the primacy of its result. It rests on the first, simplest, best known, unprovable elements of thought, the *πρώτα καὶ ἀμετάβλητα*, which are not themselves in the strict sense matters of apodictic science, they are *ἀμετάβλητα*. In all the intermediate processes of scientific proof there is involved generally this dependence upon previously established principles, and, when apodictic science is concerned, these principles are themselves established principles, are seen to be the prior ultimate elements, assumptions in thought about things, as one may provisionally describe them. The peculiar connexion involved is simply what we understand by the principle of syllogism. No syllogism is possible without the universalizing element, the *καθόλου*, and knowledge in its essence is universalizing. The conclusion of the syllogism is the universal, which is attached to the subject of the conclusion or closing together of the two aspects of all thought and being, the universal and particular.

The fuller explanation of apodictic truth refers us to three points of extreme importance in the Aristotelian theory of knowledge, the precise nature of the *καθ'αυτὸν*, which presents itself as the characteristic of the *ἐπιστήμη*, the nature of the *ἐνδεχόμενα*, or the *ἐνδεχόμενα* in things, on which the possibility of *ἀποδεικνύναι* is founded, and the forms of thought through which the universal and particular facts are subjectively realized. The three are most closely connected, and as they involve the main distinctive of the Aristotelian philosophy, we must give a general sketch of them.

First then of *τὸ καθ'αυτὸν*, the characteristic term in the explanation of knowledge. This notion is essentially double-sided. On the one side it is the universal of empirical knowledge, the generic or *κατὰ γένος* of the *ἐπιστήμη*, the *κατὰ γένος* of the *ἐνδεχόμενα* or ground of the empirical universal—it is *τὸ καθ'αυτὸν κατὰ γένος*, that which is in, for, and through itself, the essential. Now the essential, *κατὰ γένος*, is, in the first place, either that which enters into the composition of the *ἐνδεχόμενα*, or, finally, that which is *ἡ ἑστὶν* as the cause or ground of a fact or event. Thus the function of thought (of apodictic) is the exposition with reference to a determined class of objects of all that necessarily inheres in them, on account of the elementary facts which determine their existence in the world. In this range of knowledge, the *ἐνδεχόμενα* are not knowledge, but in these individuals the elementary parts, causally connected, and leading to ulterior consequences, form the general element about which there may be demonstrative sciences. The thought of the *ἐνδεχόμενα* is not a mere *ἐνδεχόμενα* but has the character of the peculiar restriction of its very nature the subjective rule.

zation of the notion of things, and the principles expressing this restriction, the logical axioms, may be appealed to if demonstration be opposed groundlessly, but these axioms do not enter into the process of demonstration. "When the apodictic process has attained its end, that is, when all the universal propositions relating to a given class, with insight into the necessary character of the predication in each case, have been gathered up, then the *καθόλου* of knowledge in respect to that class has been realized."⁸

14 Probably the example of apodictic truth Aristotle bases chiefly in mind is mathematical science, and in his treatment of the characteristic marks of this doctrine most of the peculiarities of apodictic occur. In mathematical science abstraction is made of all that is extraneous to the objects considered, of those qualities which give to them their physical existence, and the result is what is not to be conceived as entities, self-existing. They are not even to be conceived as existing only in mind, as ideal types, they truly exist in things, but are considered separately (*ἐξ ἀπαρτησεως*). The chief principles of mathematical science are few and definite, and the proof proceeds by deduction from them to the particular theorems known to the concrete and relatively more known. As in the proof generally, so in mathematical demonstration, an essential quality (*κατὰ φύσιν ἀπὸ αὐτῆς*) may be proved of a subject, and yet such quality may be still accidental, i. e., not predicated of the subject as such, but as a consequence of its nature. The truth is deduced from the constituent mark of that which enters into the subject, as, e. g., a given figure's exterior angles are equal to four right angles. Why? Because it is an isosceles triangle. Why has it an isosceles this property? Because it is a triangle. Why has a triangle this property? Because it is a figure. Why has a figure this ultimate, it completes our knowledge, *καὶ καθόλου τὴν τέχνην*. Thus the range of mathematical proof extends from the *εἶδη*, the original definitions, which at the same time assume the existence of the things defined, through the determinations *κατὰ φύσιν* to the qualities which are predicated of the subject as such, and finally to the proof to be in a sense *κατὰ φύσιν*, while a continuous series of middle notions concerning which there cannot be much ambiguity, effects the transition. Moreover, in mathematical science, one can see with the utmost evidence the correlation of reason and sense, which will presently be seen as the basis of all knowledge, and the general history of knowledge. The *εἶδη* are not to be conceived as innate, but as possessed before experience. They are seen or envisaged, intimated in perception by *αἶσθησις*, and induction here as elsewhere is the process by which perceptions are gathered together for the reflective process of abstraction. The *εἶδη* are not innate in any individual, more evidently than in any other case, it is visible that the *εἶδη* of thought and sense. The demonstration which employs a diagram does not turn upon any properties of the diagram which are there for some only, not for reason, but upon the general elementary properties of the diagram, which are the basis of its development, and which is potentially contained in the *εἶδη* and the *αἶσθησις*. Mathematical thinking operates is brought forward into actuality by the constructive processes through which the proof is mediated, and the potential knowledge contained in the intuition of mathematics becomes actual through the process of constructive thought.

Finally, the relation of pure mathematical reasoning to that found in sciences generically one with mathematics, *e.g.*, optics, astronomy, harmonics, &c., furnishes an interesting example of the relation between reasoning based on fact and on causal ground.⁹

16. The process of *anagoge* generally and of mathematical demonstration in particular has brought into clear light the prominent characteristic of knowledge according to the Aristotelian view. Knowledge must always be regarded from two sides, as having relation to the universal, and as bearing upon the particular.¹⁰ It is an *anagoge* from the particular to the universal, and from the universal to the individual. The fundamental notion of *anagoge* is that the integral element in the Aristotelian theory of science, but also the guiding principle in his scientific method.¹¹ In all cases we require to keep in mind the necessary correlation of the particular facts and the general grounds, the multiplicity of effects and the unity of causes. The particular is not apart from the other. Universals as such are not at all other than the particulars. There are no grounds of existence. Particulars, such as infinite, indivisible

¹¹ This is excellently put by Bucken, *op. cit.*, pp. 44-55.

comment is induction, of the nature of which something has already been said. The obscure chapter in which the formal analysis of induction is undertaken, a chapter which has much exercised the ingenuity of commentators,¹ presents difficulties of varied kinds. An opposition is indicated between syllogism and induction, yet induction is treated as a kind of syllogism, that is, freely interrelated, induction is so analyzed as to show that in it, also, there is the union of general assumption and particular detail which is characteristic of syllogistic reasoning. Further, Aristotle seems to waver between induction as a kind of inference, through which we arrive at general principles, and as a species of proof, and his teaching is therefore perplexed by the want of some clear statement regarding a difficulty in the theory of induction, which is still far from perfect solution. For, according to Aristotle, induction *as such*, starting from the particulars of sense, and proceeding by comparison of similar cases and enumeration of all the similarly constituted members, never, even when the enumeration is complete, attains to probative force.² It is still a syllogism of *fact*, not of ground or reason, there is a distinction of kind between the survey of empirical detail, even when complete, and the assertion of causal connection between the characteristics of the class and its deduced properties.³ Thus, perception of the law (*νόμος*) from induction is a kind of new element in the process; it is recognition by means of the empirico-critical survey which is the essence of induction.⁴ Induction makes clear only, and does not prove.⁵ If we interpret according to more modern phraseology, this peculiarity may be expressed as the distinctive feature of inductive research based on facts or effects. We do not regard the inquiry as terminating in the establishment of a law until it is possible to reverse the process and show that from the assumed cause the effects do actually follow. Otherwise we have a conclusion of "coexistence" merely—an empirical rule or generalization. If, bearing in mind these sources of difficulty, and also the conviction which for Aristotle always obtains between empirical details and grounds of reason, we consider the example given in the obscure chapter before us, some light may be cast on the exposition there given. The example selected is one touched upon by Aristotle in other two passages, in the treatises on *Metaphysics* and in *Physics*. In *Anal.*, II, 18.⁶ As regards the first of these, reference is desirable only to bring out the fact that causal nexus is the *καθόλου* in question, the second is of the utmost importance as clearing up what has always seemed an obscurity in the account of the inductive syllogism. In chapters 15-17, *Anal. Post.* II, Aristotle considers the relation of cause and effect as the essential basis of proof, and he points out with much clearness the difference between the fact as cause of knowledge and the cause as ground of existence and proof. In some cases cause and effect are so united, so reciprocal, that we may infer from one to the other. But the doubt arises, may there not be a causal nexus for any given attribute in which case all such inferences from effect must become problematical. Aristotle's solution is remarkable, both in itself and in its bearing on the inductive syllogism. Suppose the attribute β as found in all individuals of a class A , and also in individuals of class B, C , etc. In order to discover the cause, investigations must be carried on until we have a defined number of classes A, B, C , etc., in all of which β is found, and which comprehend all cases of the presence of β . Then that which is also common to A, B, C , etc., may be regarded as the cause of β , say α , an attribute α . If this attribute α be really the cause of β , it will enter into its definition; it will be its definition. There must, however, be a connection of α and β of this universal and reciprocating kind, and yet a might not be the cause in question, it might be only a fact from which β could be inferred, the real cause γ , which gives rise to β , lies in the background. Characteristic of causation, then, is constant reciprocal conjunction of facts. Even if it be admitted, then, that there may be more causes for a phenomenon than one, it will yet be true that each of these causes will be manifested in one class of phenomena where there will be the universal reciprocating coexistence that is characteristic of the relation in question. Thus the attribute longevity observed in all animals and in human beings may be due to different causes, e.g., to absence of gall in the one case, to predominance of solid, dry matter in the other. But in each case there will be a definite species characterized by the constant conjunction

of the cause and the effectum, the whole class long-lived animals and the class gall-less animals will coincide.

Turning now to the chapter on inductive syllogism, we find induction defined as inference through the minor that the major belongs to the middle. Here evidently major and middle are regarded not as determined by form only but naturally distinct, and we must assume that by middle term we are to understand the ground or reason of the attribute (major term) characteristic of a defined species or group (the middle term). Were our knowledge complete and scientific, we should be able to express this in apodictic form—whatever animal has no gall is long-lived, man, horse, etc., animals having no gall; therefore they are long-lived. The progress of knowledge, however, may be from the empirical details. We may have given to us the fact of the attribute, long-liveness, in the group of animals, man, horse, etc., and discover that these long-lived animals are also wanting in gall. If then, in accordance with the rules above sketched, there can be discovered a reciprocating relation between want of gall in animals and long-liveness, if we can constitute a class distinguished by conjoint presence of gall-lessness and longevity, we have the basis for an inductive proof. We may infer therefrom that gall-lessness *is, in this species*, the cause of longevity. Such a reasoning is founded on particulars given, and as the coexistence is given, the conclusion seems to be immediately drawn; there does not appear to be mediation or use of a middle term; nevertheless the middle term is implied, not in the supposition that the two classes reciprocate, but in the transference from empirical coexistence to causal nexus.

Aristotle's mode of stating this argument has presented so many difficulties of interpretation that various emendations have been proposed. Grote, e.g., who has not apprehended why the class long-lived animals should be taken universally—"we are," he says, "in no way concerned with the totality of long-lived animals,"—suggests an emendation which makes the essential part of the induction turn upon the extension of what we know regarding some gall-less animals to all of that class. But this is not the inductive step according to Aristotle. Induction has not to prove or assume that α and β , found coexisting in some members of a species, coexist in all of that species; this the universe of discourse must grant as the basis of the argument. The inductive step is the transference from this universal coexistence to causal nexus. Apodictically, we should say, if α is the cause of β , then all A which possesses α possesses β ; thus reasoning from cause to effectum. Inductively we say, all which possesses β has α ; therefore α is the cause of β . Induction, as dealing with particulars, starts with the senses, data, and resting upon the more evident fact in order to point towards the essential ground or reason, is therefore more persuasive, more palpable, more adapted for popular inquiries, and relatively more apparent. Syllogistic proof, on the other hand, is more stringent, more efficacious in establishing a scientific conclusion or position.

Aristotle's mode of dealing with induction, in so far at least as any specific process is designated by that term, seems on the surface to diverge widely from modern logical theory, and we look in vain in his analytical researches for consideration of the methods of observation and experiment which has come to be recognized as the essential portion of a doctrine of inductive reasoning. Yet it may fairly be argued that in modern theories the term induction is used with great laxity, so as to cover either all processes connected with scientific method or some one special variety of scientific reasoning, and that the difference between the Aristotelian and modern views

¹ The following is the relative position of chap. 28 of bk. II of the *Anal. Post.*—"Now induction and syllogism share in the same nature, but differ in the manner of the means of the conclusion term that the major term is predicable of the middle" (that is to say, of coming from given facts that an attribute found in all of them is predicable of some other attribute also found in all of them). The example, if β be the middle term, A and B the extremes, we know, by means of C , that A is predicable of B ; for this is the inductive process. Thus let A be long-lived, B the want of gall, C individual long-lives (as long-lived). If A is predicated universally of C (that is to say, the attribute A is found in all the examples before us), "for also that which is long-lived is long-lived" (that is to say, as given fact, gall-lessness and longevity in the species group, before we coexist). If, wanting gall, thus is predicated universally of C , if then B and A be reciprocally connected, it does not extend beyond the middle term. Thus we do not find other animals than the long-lived animals enumerated which are devoid of gall; it is necessary that A should be predicable of B . For it has been shown previously that if two terms are predicable of the same thing, and if the extremes reciprocate with one of them, then the other of those predicable will be predicable of that with which the first reciprocates. Thus, if A is predicable of C and C is the complex of all the individual cases." The last sentence is extremely hard to interpret. The expression *β ἀναγο* occurring in it is generally the technical word for the middle term, but as in the syllogism there is no middle, for we do not find the predication, this signification would seem to contradict the words *ἀναγο* *ἀναγο*. Hamilton reads *β ἀναγο*, which makes the argument intelligible and coherent with the passage immediately referred to in *Metaphysics*, viz. *Anal. Post.* II, 21, 38, 21-22. Probably Aristotle uses *β ἀναγο* here as equivalent to *β ἀναγο* in the induction which the induction process is based upon. In the passage above, the essence of the Aristotelian induction does not lie in the universalizing of C , but in connecting in one proposition the attributes A and B found to coexist in some group C . There is thus in some no middle, for we do not reach; in another sense there is, for C is the material link connecting A and B . Aristotle then might naturally use *ἀναγο* for C , and emphasize the process of induction in which there was a reduction to a common term, viz. C . But, however, induction regarded after this fashion results merely in the constitution of a group or class characterized as possessing two attributes in common.

² On induction and syllogism, cf. Heyder, *op. cit.* II, 268, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, and chap. 3, § 1 in which this last similarity is viewed as being valid in scope than the basis of induction. This last sentence implies an enumeration, see *Anal. Post.* II, chap. 28, 29, *Anal. Post.* II, chap. 2, § 1. Thus induction even when complete is not deductive, see *Anal. Post.* I, chap. 1, C. On this distinction, see *Anal. Post.* II, 18, where a very fine description of deductive and inductive proof occurs.

³ Compare the passages above noted, and see the various expressions used in the discussion regarding the relation of universal and particular in *Anal. Post.* II, 21, p. 274, 275, 276.

⁴ *Anal. Post.* II, 6, p. 210, 33, *op. cit.* *ὅτι ἡ ἀναγωγή ἐστὶν ἀποδεικτική, ἀλλ' ἄρα ἀναγωγή ἐστιν*. Cf. *Metaphysics*, *Met.*, I, p. 288, n. On *Anal. Post.* II, 18-19, see the valuable summary by Grote, I, pp. 268-68.

temporal significance, but he also notes that in universal judgments there is no reference to any specific time, and also that the copula, the verb *is*, has no existential meaning. He is thus driven to the enumeration of a view, common among recent logicians, that the judgment is a reflective or critical act, pronouncing on the truth or falsity of a contemplated separation or conjunction of facts, while, on the other hand, the very contemplation of conjunction or separation has appeared as the essence of the judgment. So, in dealing with opposition, he distinguishes contradictories from contraries, and is inclined to refer the second to the given nature of facts, whereas extreme opposition of members falling under the same genus is presented. Modality, likewise, he treats confusedly, in the assignment of the modal relations to the predicate does not sufficiently determine their place in a theory of judgment, nor explain the relation in which they stand to the judgment as the simplest activity of thought.

Further, in dealing with the quantity of judgments, Aristotle is perplexed by his own theory of what constitutes generality. He is compelled to throw together universal judgments of a totally distinct kind,—empirical and rational, as one may call them,—and though the underlying view that empirical universality is the expression of, and is dependent on, rational consciousness is sufficiently clear in the doctrine of proof, it is not carried out to its consequences in the doctrine of judgment. Finally, to note only the crowning difficulty, the theory of proof and of definition turns upon the nature of the essential connexion of attributes in a subject, but the explanation of essence is precisely the business of the system of a theory of essence is not wanting, but it does not seem possible so to unite them as to form a consistent whole. The greatest obscurity still hangs over the fundamental part of the system, the nature of the *spora* which are apprehended by *voia*, of the specific nature of attributes *essētia* to their subjects, and of the *forma hypotē* from which particular sciences start. That the *hypothēsis* *essētia*, so frequently adduced as integral parts of proof, are analytical judgments¹ cannot be accepted without such qualifications as to render the use of such a term misleading, but what their precise nature is remains in the Aristotelian system undetermined.

Logic from Aristotle to Bacon and Descartes.

20. The long history of philosophic thought from Aristotle to the beginning of the modern period furnishes no new conception of logic so complete as that of Aristotle as to require detailed treatment, but exhibits variations in special additions, corrections, and new points of view numerous enough to account for a certain radical change in the mode of regarding logic which is, for our present purpose, the only interesting feature. This change may perhaps be expressed not inaccurately as the tendency towards formalizing logic. Gradually the Aristotelian came to have his boundaries extended in one way by the introduction of new matter, and narrowed in another by restriction of logical consideration to one special aspect of knowledge. Much in the history of this movement still remains in obscurity, but the general result is sufficiently clear. The periods into which this historical development of logic throughout this long interval may be naturally divided, with their main characteristics, are the following: (1) *The Peripatetic School*, represented by Theophrastus and Eudemus, following in the main the Aristotelian tradition, but deviating in certain fundamental respects, and on the whole treating the matter of logical research as though it were separate from and independent of the theory of knowledge as a whole. To this school is due the distinct recognition of the hypothetical and disjunctive proposition and syllogism, and the more complete enumeration of the possible valid modes of ostensive reasoning. In both cases the additions are made to turn upon purely formal considerations. The hypothetical and disjunctive judgments are treated as given *termini*, to be discussed in ordinary language and expression, not as resting upon any fundamentally distinct principle or activity of thought.² The addition of five indirect moods to those recognized by Aristotle as belonging to the first class proceeds on the purely formal ground of difference in position of the middle term in the two premisses. (2) *The Epicurean and Stoic Logics*. Of these the Epicurean presents no points of interest. The Stoic logic, on the other hand, is the first example of a purely formal doctrine based on and associated with a thoroughly scientific theory of epistemology. In essence the Stoic doctrine is identical with that of Aristotle, above noted, and it is interesting to observe that, under the purely nominalist theory, logic becomes almost identical with the doctrine of expression, or rhetoric. The theory of naming, and that of the

conjunction of names in propositions, are the fundamental portions of the body of logic. Naturally the Stoic doctrine tended to increase the bulk of logic by introducing numerous disjunctions of language, and by signaling varieties of judgment dependent on varieties of verbal expression. (3) *The conception of Logic among the Romans*. Here there must be distinguished the quasi-rhetorical logic, such as is found in Cicero, which is altogether Stoic in character, and the Aristotelian logic, as developed by Boetius with the additions of the later commentators. In Boetius one notes specially the technical or formal character of the treatment, which was of special importance historically, from the fact that the earlier scholastic writers derived their main knowledge of logic from certain of the treatises of Boetius. (4) *The scholastic Logic*. On the details of the scholastic logic it is not necessary to enter, but there must be noted the following points as of interest in determining what may well be called the current conception of the Aristotelian logic in modern times. The earlier scholastics, in possession of but few of Aristotle's writings, added nothing of importance to the body of logical resources, and the permanent aspect of discussion, the nature of universals, did not, through any of its solutions, affect the treatment of logical doctrines. The introduction of the body of the Arabic writings was contemporaneous with the introduction of the Arab writings and commentaries into western Europe, and there grew up therewith a more developed treatment of what may be called the psychological element of logic. The logic of the later scholastics is characterized by two points of interest, historically unconnected, but having a natural affinity,—the one, the introduction of an immense mass of special disjunctions, mainly verbal, making up the body of the *Perma Logica*; the other, the influence of the nominalist conception of thought.³ The peculiarity of the nominalist view is the severance of immediate apprehension from discursive thought, the assignment of all matter of knowledge to the one, and of all form to the other. But form, under this conception of discursive thought, can be found only in the generalizing function of signs or names; accordingly the fundamental processes of logical thought are regarded as so many modes of application of names. The later nominalist logicians were thus naturally led to the existence of immense subtleties and digressions on the theory problems of the *Perma Logica*, while at the same time the peculiar inner difficulty of the theory became apparent as the consequences were worked out. (5) *The Renaissance against Aristotelianism and the Humanist Modification of Logic*. Little of positive value for logical theory is offered by the numerous works representing this stage of historical development. Yalla, *Logica*, the other, the influence of general criticism in general spirit and detail, present a rhetorical-grammatical logic that resembles most closely Cicero's eclectic reproduction of Stoicism. Ramus, the only logician of the period with historic renown, contributes really nothing to the history of logic, his innovations consisting mainly in the deletion of the most valuable portions of the genuine Aristotelian logic, the insertion of preface and interesting examples, and finally rearrangement or redistribution of the heads under which logical doctrine was expounded. The Ramist school, most numerous and flourishing, produced no logical work of the first importance.⁴

The net result of this whole period was the severance of a certain body of doctrine, formal in character (the theory of second intentions), from theory of knowledge generally, and from all the concrete sciences. The boundaries and even the functions of this doctrine remained unified, for difference regarding fundamental points of extra-logical theory led to difference in mode of treatment, as well as to difference in conceptions of the end and value of logic.

Logic of Bacon and Descartes.

21. Modern reform of logic, by which may be understood the attempt to place logical theory in a more close and living relation to actual scientific method, begins with Bacon and Descartes. To both the scholastic logic presented itself as the essence of a thoroughly false and futile method of knowledge. Neither had the acquaintance with the genuine Aristotelian system enabled in order to distinguish the elements of permanent value from the worthless accretions under which these had been buried, and, as a natural consequence, the views of both have a far closer resemblance to the Aristotelian doctrine than might be supposed from the attitude of opposition common to them. Both thinkers were animated by the spirit of reformation in science, and both emphasize the practical and of all speculation. For both, therefore, logic, which to neither is of high value, appeared to be a species of practical science, a generalized statement of the mode in which intellect acquires new knowledge, in which the mind proceeds from known to unknown.⁵ But such a conception of logic is, if the expression be permitted, formal; that is to say, the actual province of logic is not determined thereby, but aware determination from

¹ As Zeller will have it, see *Ph. d. Gr.* II, § 321, n. Doubtless Aristotle does define an essential attribute as being one contained in the subject or one of which the subject notices is an integral part; but this relation of *essētia* to the definition is not to be identified with the modern view of the analytical relation of subject and predicate.

² The nature of hypothetical inference and the law are recognized with the greatest distinctness by Aristotle. From his theory of essence as causal, and any distinction of kind between an epistemic (epistemic) syllogism and a hypothetical of the type contemplated by later logicians was impossible and needless.

³ The first of these is no doubt as Freilich has laboured to prove, Byzantine in origin, but it still remains doubtful whence the Eastern logicians drew. The most probable source is the Stoic writings.

⁴ See note C, p. 608.

⁵ Comp. *Princip. Phil.*, Pref., *De Aug. Sc.*, bk. I, chap. 1, 2.

the further idea of the nature of knowledge and the ultimate constitution of that which is to be known. When this point is reached, a radical divergence presents itself between the views of Descartes and Bacon, consequent on which appears a radically divergent statement of the main processes and methods of logical theory.

To Descartes the ideal of cognition is the mathematical, that is, in which from assumed and distinct data we proceed by strict sequences of proof to determine accurately and completely the nature of complex phenomena. Such an ideal, extended so as to embrace knowledge as a whole, dominates the whole of the Cartesian speculation, and, as in the case of the Socratic doctrine of knowledge, is the ground of the Cartesian doubt. Perfect certainty, i.e. clearness and distinctness of principles, logical consequentials, &c. deduced from them, and exhaustive enumeration of details—such are the characteristics of completed knowledge. There follow naturally therefrom the main processes of knowledge—*intuition*, by which the simple data and axioms are apprehended; *induction*, or exhaustive enumeration of the elementary factors of any phenomenon; *deduction*, or determination of the complex as the necessary result of the combination of simple factors. To the processes of induction and deduction, when viewed more generally, the titles analysis and synthesis may be given.¹ On other portions of logical theory Descartes does not enter, and the text-books of the Cartesian school, even the celebrated Port Royal logic, do little more than expound with some freshness such of the older material as seemed capable of harmonizing with the new conception.

Two things only require note in respect to the Cartesian logic, apart from its freshness and completeness, the one is the obscurity which hangs over the nature of intuition, the other is the step in advance of the scholastic logic effected in the assimilation of deduction to synthesis. As regards the first, the criteria laid down by Descartes, viz. clearness and distinctness, are unsatisfactory and ambiguous. It is evident that he implied under these clear and distinct recognition of necessity in the data, or principle, but the nature of this necessity is never made clear.² As regards the second, it was of importance to signalize, as against the scholastic view, that the universal in thought or reasoning was not only of the nature of the class notion, that genera and species were not necessarily natural, but were themselves products of the mind, formed by reasoning, and based upon essential connexion of facts. In this Descartes was but returning to the genuine Aristotelian doctrine, but his view has all the advantage derived from a truer and more scientific conception of what these connexions in nature really are.

32. What is the logic of Bacon springs likewise from the peculiarities of the underlying conception of nature. The inductive method, expounded in the *Novum Organum*, as, however, only part of the Baconian logic, and, since it is commonly regarded as being the whole, a brief statement of what Bacon included under logic may here be given.

Turning logic as the doctrine which deals with the use and object of the intellectual faculties, Bacon divides it (in this approximating somewhat to the extended division of the Stoic logicians) into (1) the art of inquiry or invention, (2) the art of examination or judgment, (3) the art of memory, and (4) the art of elocution or tradition. The third and fourth divisions are unimportant; the first and second might be called respectively the theory of the acquisition of knowledge and the theory of evidence or proof. The art of inquiry is subordinated to the art of the discovery of arts and the art of the discovery of arguments. The second of these Bacon regards as identical with the *Topos* of the Greek and Roman dialectic, and therefore as of comparatively slight value. Of the first there are two main branches,—(A) *Experientia Literata* and (B) *Interpretatio Naturae*. The art of judgment has two subdivisions—*the examination of methods of reasoning*—induction and syllogism—*which resembles the older analysis*, and *the examination of errors of reasoning*—whether these be epistemical, i.e. the logical fallacies of the older doctrine, or errors of interpretation to be removed by careful criticism of scientific terms, or arising from erroneous tendencies of the mind (the doctrine of *idola*)—*which resembles the older treatment of dialectic*.

The peculiarity of the Baconian logic, then, must be sought in the processes included under the art of discovering arts or knowledge. Among these the syllogism is not included. It is a process with no practical utility, it involves premises of which the truth is simply assumed, and consequently its conclusions can have no validity beyond that of the premises. Its efforts to determine the particular from the general, but in fact nature is much more subtle than intellect, and our generalizations, which are but partial abstractions, are quite inadequate to afford exhaustive knowledge of the particular; it throws no light upon the essential part of cognition as a process

in formation, viz. the method by which we are to obtain accurate notions of things, and judgments based on those notions. Moreover, the deductive or syllogistic procedure favours and encourages the tendency to rush generalization, to the formation of a universal axiom from few particulars, and to the uncritical acceptance of that axiom. If syllogism exist at all, there must be a prior process, that of generalizing by rigid and accurate methods from experience itself. Syllogism is not entirely worthless. It is of particular service in some branches of science (e.g. the mathematical), and generally may be employed so soon as the principles of a science are well established, but it is a subordinate and secondary method.

The art of discovery, then, is the method of generalizing from experience. What this method shall be depends entirely on the thinker's conception of experience. Now Bacon's conception is perfectly definite. Observation presents to us complex natures which are the results of simpler, more general forms or causes. From the complex phenomena these forms are to be sifted out by a methodical process of analysis and experiment. A general proposition is one stating the connexion between complex natures and their simple forms or causes, it is, therefore, the result of a graduated process. No doubt there may be generalizations based only on an ingenious comparison of the complex phenomena as they are presented to us, such a process Bacon calls *Experientia Literata*, and the maxims recommended for it much resemble the ordinary methods of experiment, but truly scientific knowledge is only to be obtained by the complete inductive method. The characteristics of this inductive method follow at once from the nature of the object in view. The fact which is sought can be detected only by examination of cases in which the given complex effect is present, in which it is absent, and in which it appears in different degrees or amounts. By a critical comparison of these cases we may be able to detect, and, were the enumeration exhaustive, we must infallibly detect, by process of exclusion or elimination, a phenomenon constantly present when the effect is present, absent whenever the effect is absent, and varying in degree with the effect. Such a phenomenon would be the form in question,—the cause of the given fact or attribute. Exhaustive enumeration is, of course, in itself, and therefore the method of exclusion can never be perfectly carried out, but all additional aids have significance only as supplying in part the place of exhaustive enumeration. We may, on the basis of a wide examination, frame a first generalization (*first vintage* as Bacon metaphorically calls it), and proceed to test its correctness by carrying out the critical comparison with it. If we were to proceed under the guidance of our leading principle, take advantage of certain typical cases presented by nature, or force cases by experiment in such a way as to supersede the enumeration. There are *perogrative* instances, critical phenomena, helpful in discovery of the cause of a phenomenon. Of other *anecdotal*, or rules to which under the titles are given by Bacon, and it would be hazardous to conjecture as to their significance.³

The Baconian logic, then, or at least what is peculiar to it, is thoroughly conditioned by the peculiarities of the Baconian metaphysics or conception of nature and natural processes. As to the novelty of the logic, this to us does not appear to lie in the mere fact that stress is laid upon induction, nor do we think it correct to assign to Bacon the introduction of the theory of induction as an integral portion of logic. But it consists in the new view taken of what constitutes the universal in thought, a view which may be inadequate, but which colours and affects every process of thought, and therefore every portion of logical theory. It is but the sequence of Bacon's narrow view of the essence of syllogism that he should set induction in opposition to deduction, and regard syllogism as of service only for communication of knowledge. His inductive methods are throughout syllogistic in this respect, that they take the processes of thought involve the combination of universal and particular. Experience is nature itself, and that is to say, viewed under the light of a general idea or notion.

Logic on the Basis of Psychological Empiricism.
Locke, Hume, Mill, Comte.

23. The universal element in thought which is recognized by Bacon as present received from him no special treatment. His theory of the nature of knowledge affords no explanation of the origin, significance, and validity of the notions involved in inductive procedure. The *Essay on the Human Understanding*, which carries out in the domain of inner experience the practical tendency of the Baconian method, supplied from the point of view of individualism the metaphysical theory common to both, a certain psychological theory of the universal element in knowledge, and thereby afforded a new foundation for logical doctrines. The *Essay* contains, in an unsystematic fashion, much that bears directly on logic (e.g., the whole discussion on names, the classification of the significance of

¹ See *Regulae ad directionem ingenii*, Nos. 2, 3, and especially 7. The celebrated rules of speculation (*de Methodo*) are only a more popular statement of the same process.

² The ultimate standard is, no doubt, necessity for a thinking subject. What never is connected with the existence of the thinking being without it this existence is inconceivable. But to give this ideal its own position, see the first, the *Copius error*, is for Descartes the fundamental difficulty of his philosophy.

³ See *Op. II*. In addition to perogrative instances there are mentioned—supporters of induction; destruction of induction; variation of the investigation according to the nature of the subject; preference of the subject to the investigation; application to practice; preparation for investigation; ascending and descending scale of existence.

judgments, the criticism of syllogistic argument), but of more importance than those detached and direct portions is the general principle which underlies the whole view of human knowledge. This principle is unity that of psychological genesis. All the complex facts of knowledge are regarded as mechanical compounds due to the coherence of simple data, the facts of inner and outer sense. The method of Locke is that which underlies and determines all the logical work of one very important school of logicians.

It is not difficult to enter into details of Locke's own contributions to the foundation of logic. But it may be pointed out that from his position there were two possible lines of development. In his view the primitive impressions, the facts of inner and outer sense, were in themselves primitive facts of cognition; they were cognitions (it is the very essence of Locke's method to identify a simple impression of sense with the knowledge of a simple sense fact). The processes of abstraction, comparison, *i. e.*, judging and reasoning, were exercised upon their data, and these products were, in consequence, of a secondary and, so to speak, artificial character. It was natural that a thinker who identified impression of sense with knowledge of a sense fact should maintain that the secondary formations of thought (general ideas, general propositions, syllogisms) were not indispensable for cognition; that we could and did reason from particulars to particulars. At the same time Locke admitted the secondary processes as having actual existence, and in one important case (that of the judgment of coexistence, with which may be taken the idea of substance and of real relation) seemed to allow that in judgment something was added to the primitive data. It was possible, then, for development from Locke's position to proceed either by offering an explanation of the added elements, which should be in stricter harmony with the fundamental doctrine of psychological genesis, or by throwing them entirely out of account and concentrating attention on the primitive data as the only materials of cognition. The first is the line taken by Hume, which finds its logical completion in Mill; the second is the line taken by Comenius.

Hume has an easy task so long as he merely subjects Locke's position to negative criticism, for the added elements, the ideas of substance, relation, cause, &c., are clearly inept and defenceless when the facts to be linked by them are already contemplated as so many completed, isolated cognitions. But where connectedness of cognition is in question, and where some explanation is demanded of the relations which seem to supply the universal rule in thinking, Hume's task is not so simple, and his final answer that these relations are psychological growths or products of association is neither satisfactory in itself nor quite in keeping with other portions of his doctrine. Hence, however, we find the first thorough attempt to construct a theory of knowledge on the basis of psychological empiricism or individualism, and the first contribution to a doctrine of inductive proof as portion of this more comprehensive theory. Briefly, so far as logic is concerned, Hume offers as explanation of the universal in thought association of ideas, but does not treat of logic specially or in detail.

The complete statement of the theory of knowledge from the psychological point of view is that contained in Mill's *System of Logic*.

The aim of that work is the exposition of the theory of knowledge. Now knowledge, the term being taken in a wide sense, is characterized by one quality mainly, *vis*, evidentiary force. For every item entering into the sum of our beliefs at any moment, immediate perception being discontinued, there may be reasons advanced, adequate or inadequate. The exposition of the relations between beliefs and their evidence or grounds is logic, and logic is thus in one sense or formal, inasmuch as the relations of evidence and belief are general, not dependent on the special nature of the facts believed, and in another sense real, in that knowledge is conceivable only in strictest relation to the things known.

Now, the exposition of the general nature of grounds of belief is in fact identical with a theory of the universal element in thought or cognition, and this theory is the essential portion of Mill's logic. It being assumed that the facts with which knowledge is concerned are minds, bodies, states of consciousness, and the relations (coexistence, sequence, identity) among those states, and that propositions express, therefore, existence, coexistence, sequence, or resemblance, on what is based any inference going beyond a present perception? The propositions which make up cognition, strictly so called, are not more expressions of momentary states; they are expressions of belief regarding the more or less constant relations of fact. They are, in fact, cognitions. The theory of proposition and of reasoning is one. On what, then, do such conclusions rest?

The warrant for any conclusion based upon experience, and referring to experience itself, can be found only in experience or in some principle derived from experience. It may be shown that evidence for a conclusion is adequate, if we can compare this evidence with the kind of evidence on which a wider conclusion, frequently or constantly verified, rests. This comparison of particular evidence with more general evidence is the preliminary

answer furnished by Mill. But what is the general evidence referred to, and what is the principle founded on it? The general evidence is the repeated experience of constancy of connexion among groups of phenomena, and the principle founded on it is that of the existence of uniformity or rather of uniformities in nature. The evidence and the principle are purely psychological in character, that is to say, repeated experience, beginning with familiar cases and extending itself as time goes on, produces, by the natural laws of association, an assumed belief that phenomena as a whole, or at least in the main, are connected together in constant, uniform, invariable series. Such a belief, once established, serves as an ultimate criterion of proof, and as an index for research. We proceed on our investigations in the light of this principle, and the tests by which we estimate the validity of evidence for any particular inference as to uniformity are generalized statements deducible from it. So soon as our evidence is of such a character that, in the case before us, repeated the inference of uniformity is warranted or the general principle must be held not to apply to this particular case, we have proof as cogent as experience can afford.

The universal in knowledge, then, is this naturally formed assumption regarding the course of nature. The logic of knowledge is the exposition of the modes in which evidence is obtained, of the tests by which its validity is estimated, and of the forms in which evidence and conclusion are connected.

The characteristic features of the subordinated processes of proof are at once deducible from this fundamental view. For if the simplest form of inference by psychological law, the transition effected by association from one particular case to another resembling it, and if the essence of proof consist in comparison of the evidence for any one conclusion with the type of evidence for the general assumption regarding nature (or at least a wider portion of nature), it is evident that syllogism, in the ordinary ascription of the term in which it implies a concrete general proposition, a particular assumed thereunto, and a conclusion, is neither a primitive form of inference nor a valid mode of proof. Doubtless we do in reasoning employ general propositions in order to express the determination of some particular belonging to the same class, but the general proposition is itself a conclusion, resting on evidence of the same kind as the one described, and the essence of syllogistic reasoning is not the subsumption of a particular under a general in which it is included, but the expression of belief that the evidence for the general proposition is adequate to cover all the particular cases, including those which have not been taken into account in formulating the general major premise of a syllogism is the record of a previous induction, and the syllogistic process, bringing forward a new case, is a valuable method for testing the adequacy of the previous generalization. As to generalization itself, this basis of evidence to be sought in experience, apprehended by observation and reflection, did experience present to us isolated phenomena, *i. e.*, phenomena so arranged that enumeration of the elementary constituents, whether antecedents or consequents, were possible, then our inductive procedure must be regulated by these canons or axioms which express the kind of evidence already referred to as establishing uniformity. These canons or axioms, however, are, like the Baconian method of exclusion, tests for an ideally perfect experience, and they, therefore, only lie in the background of actual scientific procedure, which has to employ other processes, both of inference and of proof. For, if we can in no way obtain more than a knowledge of the coexistence of facts, we are unable to bring our evidence into conformity with the inductive canons, save in the ideal instance in which absolutely exhaustive experience both of positive and negative cases is possible. Inferences as to law or uniformity of coexistence must here be based on numerical calculation of probability, and the canons themselves in the peculiar numerical form appropriate to propositions of probability. Further, if the phenomena under investigation be complex, so that the canons of either observation nor experiment are immediately applicable, the process of investigation must necessarily be the combined method of analysis and synthesis, and analysis, aided by hypothetical conjecture, formulating such general laws of elementary factors as are known or presumed to exist in the case in question; synthesis, combining these laws and calculating with greater or less numerical exactness, according to the nature of the matter, the probable combined effect, the whole tested by critical comparison of the calculated result with the actual phenomena. Here, as one can see, syllogistic procedure appears in its true scientific aspect as the form of thought by which we pass from the simple to the more complex, from the elementary essence or cause to the complex accident or effect. The elementary causes, no doubt, have no more cogent evidence than that which can be afforded by experience viewed in the light of our psychological assumption of uniformities, nevertheless the whole procedure of scientific investigation is recognized as being essentially of the type which is somewhat imperfectly called by Aristotle

So far, then, as the logic of Mill is concerned, and apart from the undeniable richness and completeness of knowledge with which the various processes are treated, we note but one fundamentally new feature, namely, the explanation offered of the universal element

sphere of apprehension. According to this view the whole province of knowledge is excluded from logic, and it is assumed that knowledge is somehow given, mechanically, without the co-operation of processes, if not identical with, yet strongly resembling, those recognized as logical. Herbert does not succeed in vindicating an independent place for a purely formal logic.

The Kantian Logic.

27. The critical method, which has so influenced general philosophy that all later speculation refers more or less directly to it, has at the same time profoundly modified later conceptions of the sphere and method of logic. From the Kantian philosophy there spring directly the three most important modern doctrines of logical theory,—that which, with many variations in detail, regards logic as a purely formal science, the science of the laws of thought or of the laws under which thought as such operates, and of the forms into which thought as such develops, that which, likewise with many variations, unites logical doctrines with a more general theory of knowledge, and finally that which identifies both logic in the narrower sense and theory of knowledge with an all-comprehensive metaphysic.

It is matter of history that the critical system was developed mainly from the basis of the Leibnizian logic and metaphysical theodice, and it is likewise matter of history that Kant, even in the speculative work which was to so large an extent antagonistic to these theories, remained under the influence of some of their cardinal positions.¹ In particular the view of logical thought as purely discursive, analytic in character, a view never by Kant harmonized with his general system, is a relic, most significant for the development of his logic, from the Wolfian reproduction of Leibniz's philosophy. This historic bias is not to be lost sight of in attempting to acquire a clear idea of the special place and function assigned by Kant to logical theories.

But a brief reference to the general result of the critical philosophy will suffice to introduce the more special treatment of the Kantian logic. Knowledge, or real cognition, which is analysed in the *Kritik* in reference to its origin and validity, appears, when subjectively regarded, as a compound of intuition and thought, of sense and understanding. The isolated data of sense experience do not in themselves form parts of cognition, but are only cognized when related to the unity of the conscious subject, when the subject, as it may be put, has consciousness of them. This reflex act, resembling in some respects Leibniz's apprehension, or process of uniting in consciousness, is the act of understanding, and is itself only conceived or explained. Only through its means do representations become cognitions. The forms in which the synthetic act of understanding is carried out are, as opposed to the intuitive data on which they are exercised, discursive or logical in character. Essentially they are *rules* and *principles* governing the judgments, and, as judgments, they imply a general element with which the particular of sense is combined, and in the light of which the particular becomes intelligible. In ultimate analysis it appears that no particular, whatever be its empirical character, can become an intelligible fact, save when determined through some specific act of understanding, through combination with some specific notion or general element.² Combination of particular and general is thus the very essence of understanding, the mark of knowledge as such. In every term of cognition the same elements may be discerned as necessarily present. The consideration of the ultimate modes of intellectualization, of the series of acts by which understanding subsumes the particular, draws the particular into the unity of cognition, may be called in a large sense logic. If the consideration be specially directed to the mode in which, by means of this combination, knowledge arises, and therefore includes discussion of the wide problem regarding the relation between understanding and objectivity in general (the matter of knowledge taken generally), the special title transcendental logic may be used. But if, concentrating attention solely on the kind of operation implied in understanding, we endeavour to lay out fully the modes in which understanding proceeds in the construction of knowledge, making abstraction of all questions regarding the origin, worth, significance of knowledge itself, the consideration is of a more general character, and may receive the title of general logic.³

The understanding, then, like everything else, works according to laws, the laws of its own nature. If we abstract from all that may characterize the matter considered, and take into account solely the laws according to which understanding must act, we may construct a purely formal doctrine, a theory which is rational both in matter and in form, for the matter consists of the laws of reason, and the form is prescribed by the very nature of reason,—a demonstrative theory, for nothing can enter between, which cannot be shown to have its ground in reason,—a completed theory, for although the matter of thought is infinite and infinitely varied, the modes in which the understanding must operate if unity of

cognition is to result, are finite and capable of exhaustive statement,—and a theory developed from its own basis, and standing on a needed psychology or metaphysic, but deducible from the meta idea of understanding as that which introduces unity into representations, whether given (empirical) or *a priori* (pure).

Were this the only determination of the province of logic given by Kant, the question which at once arises as to the possibility of any such independent doctrine would receive an easy solution. For it is evident that logic, as a theory of the form of thought, could consist only of a portion of the more general doctrine, by whatever title that be known, in which the nature of understanding as synthetical activity is unfolded. The distinction on which Kant lays stress between matter and form, a distinction employed by all subsequent writers of his school, is ambiguous and misleading. If by matter be meant the particular characteristics of the things thought about, in which sense we might speak of judgments of physical, chemical, grammatical matter, and so on, then to say that logic does not take this into account is perfectly right. If logic be a philosophic discipline at all, a theory in any way concerned with thinking, it is at once evident that it can in no way deal with the specialities of any particular science. But this distinction between matter and form is by no means identical with another, lying in the background, and too frequently confused with the first, the distinction of understanding as a faculty *per se* with its own laws, deducible from its mere notion, and understanding as the concrete real act of thinking. What Kant calls the meta idea of understanding, and what in other writers of his school appears as a definition of thought, is really nothing but a reference to what has presented itself in the wide inquiries of the *Kritik* as the complex nature of the synthetical activity of understanding. Kant himself never attempts to deduce from the notion of understanding the varied characteristics of logical forms, and his followers,—e. g., Hegel,—even they are consistent, start from concepts as expressing the bare notion of thought, and regard all other forms of thought as combinations of concepts.

But Kant does introduce another element into his treatment of the province of logic, one not original to him, but of the utmost importance for later developments from his point of view. He inquires what Kant calls the elements among the elements which form the matter of logical treatment, and defines these as two in number—(1) formal consequence, (2) non-contradictoriness. By formal consequence we are to understand the relation between a conclusion and its premisses, no inquiry being raised as to the truth or validity of the premisses. By non-contradictoriness we are to understand that, logically, notions, judgments, reasonings can be subjected to treatment only in regard to the absence of explicit contradiction among the factors entering into them. Thought, which introduces unity and unity into experience, must certainly introduce formal consequence and preserve analytic truth or correctness. Formal logic, then, treats only of these formal qualities of all products of thought.⁴

The detailed treatment of logic, so far as that can be gathered from the very brief summary (*Logik, Werke*, iv. 289-340), shows with the utmost clearness how impossible it was for Kant to deduce the forms and relations of thought from the mere notion of understanding, even when coupled with the principles of formal consistency and consequence. Assuming that understanding is the discursive faculty, the faculty of cognizing the many particulars through the one concept or notion, Kant deals first with concepts (*Begriffe*) as general or discursive representations. He is careful to avoid an error into which many of his followers have fallen, that of regarding *Begriffe* in a mechanical fashion as a specific kind of *Vorstellung*, distinguished only by containing a few of the marks making up the single intuitions. He rightly notes that cognition proceeds by subsuming the particulars under the common elements contained in them, and that the generality of the concept thus rests upon the relation in which it stands, as reflective ground of cognition, to the particulars. The characteristics of concepts, as possessing extent and content, are treated briefly, after the fashion familiar in the more detailed logics of his school. It is, however, when the doctrine of judgment is reached that the distinction of logic most appears with greatest clearness. Judgment is defined "as the representation of unity in the consciousness of distinct representations, or the representation of the relation of

¹ Two at least of the followers of Kant have worked out the system of logic from this point of view,—the one, Dierksen, in his *Logik*, mentioned in the introduction (1850), the other, the late Professor Demme, in his *Principien der Logik*, Kassel, recognizing the distinction between the two modes of determining formal laws, and adapting the result, and so therefore led to the error of deducing the science of the laws and forms of thought, but as the science treating of formal thought, or of the formal element in the forms of thought. In other words he recognized that the statement of the forms of thought must be introduced into logic *ab extra*, from psychology or what not, and thus logic, accepting these, has to consider the formal element (non-contradictoriness) as a condition, but to have the doctrine brought thus to its ultimate basis, for it is there apparent that there is no independent science called logic, but only one comprehensive doctrine, which may be called *logico-psychic*, or *epistemic*, embracing all thought. Illustrations of the ways in which contradictoriness manifests itself may be offered, and a careful logical grammar may thus be afforded, but these do not make up any science or theory.

² See article Kant, vol. xiii, pp. 840, 832.

³ It does not seem necessary to advert more in detail to the divisions and subdivisions of logic drawn out in the *Kritik*, pp. 38-42 (Hartenstein's ed., 1868).

Throughout the Kantian work there appears a constant tendency to regard the ego, or central unity of self-consciousness, as merely abstract, as related mechanically, not organically, to the complex of experience in which its inner nature is unfolded. This tendency finds expression in various ways. Thus the synthesis, which has been shown to be the essential basis of cognition, is regarded as on its objective side a union of intellectual function and receptivity of sense, and the contributions from either side are viewed as somehow complete in themselves.¹ Knowledge, in accordance with this, might be considered to be the mechanical result of the combination or coherence of the two, a combination which in the last resort must appear to the conscious subject as contingent or accidental. (2) Knowledge, the systematic union of universal and particular in experience, is thought as containing in some obscure fashion a reference to the most real world, the realm of things in themselves, and therefore as being, in antithesis thereto, strictly subjective. The processes of thought, by which unity is given to experience, thus manifest themselves as limited in scope, and as being the very ground or reason of the restriction of knowledge to phenomenal in opposition to noumenal reality.²

The presence of these two difficulties or perplexities in the Kantian system, which are, indeed, at bottom but one, led to revision of transcendental logic in two directions. The one line proceeded from the analysis of knowledge as the product of intellectual function and receptivity, and, uniting therewith metaphysical conceptions of varied kinds, culminated in a doctrine of cognition which, retaining the distinction between real and ideal as ultimate, endeavored to show that the forms of the ideal, i. e., of thought, and the forms of reality were parallel. Logic, under this new conception, appeared as a comprehensive theory of knowledge, the systematic treatment of the modes in which thought, conditioned by its own nature and by the nature of the reality upon which it is exercised, develops into knowledge, i. e., of the modes in which a representation of things characterized by universality and evidential force is obtained. On the whole this is the position assigned to logic by Schleiermacher, whose view is followed in essentials, though with many variations in detail, by a large and important school of logical writers.³

The second direction may be characterized generally as the attempt to develop fully what is involved in Kant's conception of thought as the essential factor of cognition. Any opposition between metaphysics as dealing with the real and logic as dealing with the ideal element in knowledge appears, in this view, as a mere effort of false abstraction to separate the nature of reality as it is from the way in which it is thought. The system of pure determinations of objectivity, which Kant had imperfectly sketched, is not to be regarded as a piece of subjective machinery, because it expresses the inmost conditions of intelligence as such. Nothing is more real than the ego, than intelligence or thought. Transcendental logic, or logic which is at the same time metaphysics, is the only discipline to which the title logic by right belongs. For it contains the complete system of the forms in and through which intelligence is realized. The notion, judgment, and syllogism are doublets of forms of thought, but they have their definite content. They are the modes in which the forms of objectivity are realized for intelligence, and are thus at once abstract and concrete. The so-called formal logic is a mere *caput mortuum*, a descriptive study of some few types of the application of thought to matters of experience. On the whole this is the view of logic developed through Fichte (and in part Schelling by Hegel), and the Hegelian system shall here be regarded as its complete and only representative.

Logic as Theory of Knowledge.

29. The position assigned to logic as theory of knowledge and the range of problems included in it are determined by the general philosophic view of the distinction between the reality to be apprehended by thought and the subjective nature of thought itself. There may be, therefore, numerous variations in the mode of treating logic with general adherence to the one point of view.⁴ In the *Deutsche* of Schleiermacher, for example, the fundamental characteristic is the attempt to unite some portions of the Kantian analysis of cognition with Spinozistic metaphysics. Knowledge as regarded as the complex combination of intellect, the formative, unifying, idealizing, and organizing or organizing of sense. The generality or common validity of cognition rests on the uniform nature of organization and on the identity of all ideas in the one

ideal system. The objective worth of cognition is referred on the one hand to the determined connection between the real universe and the organization through which the individual is part of the real order of things, on the other hand to the ultimate metaphysical parallelism between the system of ideas and reality. The primary forms of knowledge, notion, and judgment, distinct from one another only as being knowledge viewed under as stable, now as a process, correspond to the ultimate elements of the real, the permanent force or substance and its variable manifestations. Syllogism and induction, with the subordinate processes of definition and division, analysis and synthesis, are technical modes of the organization of notions and judgments, modes by which inchoate notions are rendered definite, by which incomplete judgments are rendered complete.⁵

That there is much valuable and suggestive material in this mode of regarding logic is undoubted, and in the discussion of isolated forms of knowledge, such as judgment, it is always desirable that there should be kept in mind the reference to the ultimate character of objectivity. But the whole point of view seems imperfect and open to such objections as will always present themselves when a principle is not carried out to its full extent. It may, for propaedeutic purposes, be desirable to separate the handling of logical forms from metaphysics, but such separation cannot be complete. The system of forms of reality to which the forms of knowledge are assumed to correspond must in some way enter into knowledge, and they cannot enter in as an absolutely foreign ingredient, to which knowledge has simply to conform itself. For, if so, these metaphysical questions would be discoverable only by an analysis of concrete knowledge, and they would remain as inference from the nature of cognition, not as data directly known. The cardinal difficulty which appears in all treatments of logic from this point of view is that of explaining how there comes to be known as objective system of things with characteristic forms or aspects, and it is not hard to see that the acceptance of a reality as formed is but a robe of the pernicious abstraction which gave rise to the Kantian severance of knowledge from noumenal reality.⁶ In short the position taken by Schleiermacher and his school, as final standing ground, is but an intermediate stage in the development of that which lay implicit in the cry implicit in the Kantian system.

Moreover, it is hardly possible to assume this point of view without tending to fall back into that mechanical view of knowledge from which Kant had endeavored to free philosophy. If there be assumed the severance between real and ideal, it is hardly possible to avoid that it is characterized by a certain arbitrariness. From the observed or conjectured psychological peculiarities of inner experience. The real appears only as ultimate point of reference, but in no other way determines the form of knowledge. The characteristic relations which give content to notions, judgments, and syllogisms are deduced psychologically.⁷ In the long run, it would not do to be found that the real key to the position is the belief, more or less expressed, that the systematic view of thought as comprehending and evolving the forms of reality is an unattainable ideal,—that metaphysics, to put it briefly, is impossible. To some extent this is the position taken by Lotze, whose cautious and ever thoughtful expositions are invariably directed to the elucidation of the real *modus*, the real roots of perplexity or incompleteness of doctrine. In his view logical forms are the modes in which thought works up the material, supplied in inner experience by the psychological mechanism of the soul, in conformity to the ultimate presuppositions with the aid of which alone can harmony or ethical and aesthetic completeness, be gained for our conceptions of things. But with this doctrine, which approaches more clearly than any other of the type to the metaphysical logic, there is coupled the reverse that any actual point of view from which the development of these presuppositions, their rationality, their truth, their certainty, is possible is unattainable. Our confidence in them is finally of an ethical character, and depends upon our conviction of the ethical end or purposes of all the surroundings within which human life and

¹ Perhaps the most complete treatment of logic from this point of view is that of George, *Logik als Wissenschaftstheorie*, 1888. Ueberweg, dissenting from Schleiermacher's view of syllogism and the systematic treatment of logic, does not more fully what is in his view the aspects of reality corresponding to the typical forms of knowledge. Transcendental endeavor to fill up the gap between real and ideal by emphasizing the community of character, however inexact, as the ultimate reality, and constructiveness in knowledge, the central

² Thus we find in Schleiermacher (*Phil.*, §§ 123-5) that the ultimate difference of ideal and real is accepted as simple datum. In Ueberweg (*Logik*, § 8) and elsewhere there is constant reference to an inner creation of forms, out of which are the metaphysical categories, but the actual treatment is altogether independent of these forms, and we may conjecture that, in the last resort, Ueberweg would here explain the characteristics of logical theories by reference merely to the psychological mechanism than to a supposed nature of things. See also Lotze, *Phil.* §§ 60-62, and thus approximated to the position of Beneke rather than to that of Schleiermacher.

³ This tendency, which appears in Schleiermacher and Ueberweg, and indeed in all the modern school (George's *Logik* is a notable example), is due to a lack of firm psychology, is prominent in Beneke. It is curious to note a parallel result in the logical theory of Mr H. Spencer. Mr Spencer supposes himself to be directed in referring to the nature of things, but in fact he is actually in the forms of reasoning developed by him is of psychological origin (see *Pr. of Psych.*, II § 302-3).

¹ See vol. xiii, pp 861, 862.

² It is unnecessary to consider what exactly was Kant's teaching on either of these points, or what the significance of the relative doctrine may be in his system. It is sufficient, for the present purpose, to indicate the general tendency of the work, for from the later developments take their rise.

³ See, for an examination of the more prominent members, Ueberweg's *Logik*, § 64, a work which, though not complete, is covered by the main expression.

⁴ It appears an historic error to identify the point of view here referred to with the Aristotelian. The notion of a parallelism between the forms of reality and the forms of knowledge, to be covered by the main expression, is due to whether in Aristotle or in Plato, of the doctrine that knowledge is knowledge of being.

importance, whether there remains over and above the difference between the more immediate determinations of thought and its more complex or reflective modes an essential difference in knowledge between thought and reality. In less careful critics the oversight simply leads to the contention that we shall always repeat the problem of knowing and being as insoluble, and shall view knowledge as a mechanical, subjective product.

Many of these objections doubtless result from a very simple fact, more than once alluded to in this article. Particular distinctions, apparently the most elementary, frequently involve and are unattainably apart from a developed, though not necessarily consistent or well grounded, conception of thought in general. Thus the emphasis laid upon thought as essentially subjective, as being merely the system of operations whereby the individual brings into order and coherence in his own experience what is furnished *ab extra* through the natural connection in which he is placed to the objective world, seems at first sight the most simple and direct consequence of the actually given distinction between the individual as one natural unit and the sum of things comprehending him and all others. But, on analysing more closely the title for applying to philosophical problems a view which is that of practical life, and doubtless legitimate and necessary within that sphere, we readily become aware of a whole series of speculative assumptions implicit in that view, and possibly without any adequate justification. At all events, whether or not the view be ultimately defensible, and in the same form in which it is at first assumed, it is unphilosophical to start in the treatment of a difficult and important discussion from principles so ambiguous and undetermined. The practical difference between the individual agent and the external sphere within which his individual operations are realized and which is therefore treated by him, from his point of view, as external, throws no light *per se* on the nature of the ultimate relation between the individual thinker as such and the world within which his thought is exercised. The confusion between ultimate distinctions and practical points of view is productive of most pernicious consequences not only in logic specially but in philosophy at large.

Criticism of the Chief Logical Schools.

§1. It will probably be now apparent that determination of the nature, province, and method of logic is, and has always been, dependent on the conception formed as to the nature of knowledge. Discussions regarding the precise definition of logic are not more analysing than the best mode of expressing in terms the nature of a subject actually agreed upon; variations in the treatment of particular portions of logical discipline do not arise from more or less accurate discrimination of the nature and relations of given material; nor are differences in respect to the amount to be included or excluded in the expression of difference as to the range of the same fundamental principles. The grounds for divergence are much more deeply seated, and, looking back upon the historical survey of the main conceptions of logical science, it seems quite impossible to hope that by comparison and selection certain common points of view or methods may be extracted, to which the title of logical might beyond dispute be applied. The logic, as one may call it, of each philosophical theory of knowledge is an integral part or necessary consequence of such theory; and its validity, whether in whole or in part, depends upon the completeness and coherence of the explanation of knowledge in general which forms the essence of that theory. Any criticism of a general conception of logic or special application thereof, which does not rest upon criticism of the theory of knowledge implied in it, must be inept and useless. It is not possible to include such expanded criticism in an article like the present; there remains there only on the aspect of these various logical schemes which may be subjected to special and isolated examination, viz., the inner coherence of each scheme as presented by its author. Naturally such an examination can be applied only to views which imply the separate existence of logic as a body of doctrine developing into system from its own, peculiar principles. When it is a fundamental position to deny the separate existence of logic, but is one with the all-comprehensive doctrine or theory of the ultimate nature of cognition, it is not possible to criticize such conception of logic separately; criticism of logic then becomes criticism of the whole philosophical system. In most of the views brought before us, however, a special place has been assigned to logic; it is therefore possible to apply internal criticism to the more important of these general views, and to consider how far the pretensions of logic to an independent position and method are substantiated.

From the foregoing remarks it will also have become apparent that a general classification of logical schools, as opposed to the reference of these to ultimate distinctions of philosophical theory, is impossible. A distribution into formal (subjective), real (empirical), or, as certain German authorities designate it, *Wissenschaftstheoretisch*, and metaphysical conceptions of logic is rather confusing than helpful. For the formal logics of the Kantian writers, of Hamilton, and of Maassel are distinct, not only from one another,

but from such equally formal logics as those of Hobbes, Condillac, Leibnitz, Herbert, Ulricz, Boole, De Morgan, and Jevons. Logics theory of knowledge presents quite special features when handled by Mill, or by Schlägelmacher, Ueberweg, Bencke, and Wundt. And it cannot even be admitted that the threefold classification affords room, without violence, for the Aristotelian logical researchers. There are no points of agreement and difference so unambiguous that by their aid a division can be effected.¹

§2. Few conceptions of logic contain, with so little real ground, such professions of completeness and independence as that developed in the writings of the Kantian school.² According to this view, logic is a pure science, having as its special material the form of thought, demonstrative in character and with theorems capable of complete deduction from the elementary principles contained in the very notion of form as opposed to matter of thought. But, when one comes to the examination of the system itself, one finds (a) that the notions of form and matter are much too nebulous to limit themselves readily to analysis, and that explanations of what exactly constitutes form fluctuate between a merely negative definition (whatever is not treated in any other science, philosophical or otherwise) and a psychological deduction from the assumed nature of thought;³ (b) that the really important factor in determining the contents of logical science is psychology, from which science more is borrowed than the mere preliminary definition of thought; (c) that demonstrative character rests entirely on an abstract interpretation of the laws of identity and non-contradiction; (d) that throughout the whole system there is not a trace of development, merely the reiterated application of the law of identity and contradiction, or of some confused distinction between form and matter, to logical products, the notion, judgment, and syllogism, whose nature, characteristics, and distribution are arbitrarily accepted from psychology or general criticism or vice versa. Thus, in the majority of cases, logicians who simply followed the lines indicated by Kant introduced into their system without any criticism, the fundamental distinctions contained in the *Kritik der reinen Vernunft*. The fourfold scheme of quantity, quality, relation, and modality was applied without hesitation, though in varied and always arbitrary fashion, to notions; judgments were accepted as being categorical, hypothetical, and disjunctive in kind, though the differences are altogether foreign to the logical principle applied; and generally no attempt was made to do more than treat, in an abstract fashion, some aspects of a procedure of thought determined in all its phases by extra-logical considerations.

§3. The best and most desirable result of such a procedure of thought is a logical system which is commonly associated with the name of Sir W. Hamilton spring entirely from this view of notions. For, if notions be regarded as the elements of thought, then the judgment which elaborates them can only present itself as the explicit statement of immediate relations discernible among notions. These immediate relations reduce themselves, for Hamilton, to one,—the quantitative relation of whole and part,—and, attention being concentrated on the extensive reference of concepts, the eightfold scheme of propositional forms is the natural consequence. To such a scheme the objections are manifold. It is neither coherent in itself, nor expressive of the nature of thinking, nor deduced truly from the general principle of the Hamiltonian logic. For it ought to have been kept in mind that extension is but an aspect of the notion, not a separable fact upon which the logical processes of elaboration are to be directed. It is, moreover, sufficiently clear that the relation of whole and part is far from exhausting or even adequately representing the relations in which things become for intelligent entities of cognition, and it is further evident that the procedure by which types of judgment are distinguished according to the total or partial reference to extension contained in them assumes a stage and amount of knowledge which is really the completed result of cognition, not that with which it starts, or by which it proceeds. The utility of basing logical theorems on psychological premises, a method involved in the procedure of most explications of formal

¹ Nor are more detailed classifications, such as those of Rosenkranz (*Die Methodik der Logik*, 1842), Prunt (*Logik*, 1848), Rehm (*Elemente der Logik*, 1880), of service, except when historical.

² Under this head Kant himself, for reasons above given, is not included; the view entertained by him is too different from the others.

³ Much criticism on Hamilton's confused statements regarding forms (*Elements of Metaphysics*, 428-464), is perfectly applicable to the generality of the Kantian theories on logic.

⁴ See, e.g., Krug, *Logik*, § 31 et seq.

⁵ The extension of a notion has no numerical or quantitative definiteness. To formulate the judgment as expressing definite amounts of extension, therefore, presupposes complete empirical survey of what, by its very essence, remains necessarily and is specially noteworthy in its indefiniteness. To speak of judgment as a judgment such as only *some A* is *all B* assumes total and perfect knowledge of the whole sphere of *A* and *B*. It is in the strictest sense of the word external. Hamilton, it may be added, is not at all clear in his work, and a coherent doctrine of syllogism from the point of view taken in the treatment of the judgment.

logic, may well be matter of doubt. For psychology, as ordinarily conceived, has certainly close relations with logic, but in aim and in point of view is distinctly opposed or at all events subordinate to it. The psychological investigation of thought, if carried out consistently, must take one of two forms, either that of description, in which thought, like any other mental fact, is regarded *ad extra* as that upon which attention and observation are to be directed,—in which case therefore any relations of thoughts among themselves must be of such an external nature as can be presented in the field of observation, or that of genesis, development, in which the subjective processes of mind are viewed as forms of the one grand process wholly identical with observation and the individual consciousness. Investigations from the first point of view are diametrically opposed to the logical treatment of thought, for in the latter the essential feature, the reference in the subject, with its mental forms, to an objective order within his experience is entirely wanting. Such investigation is abstract; it proceeds upon and remains within the limits of a distinction drawn in and for conscious experience, a distinction the grounds, significance, and modes of which require to be treated by a larger and more comprehensive method. Investigations from the second point of view are subordinate to logic in the wider sense, for the treatment of the subjective processes therein is illuminated and determined by the general principles regarding the nature and meaning of conscious experience which it is the sole function of logic to bring forward and establish. The psychology which Hamilton generally has in view is that commonly called empirical, and with his conception of it the two sciences, logic and psychology, are really identical.

83. A possible exit from the difficulties or assumptions of the current Kantian logic may be sought by following out and consistently applying the hint contained in Kant's distinction of analytic and synthetic thought, analytic and synthetic truth. It may be said that all thinking involves the fundamental law of identity and non-contradiction. That in these laws only is to be found the characteristic and most general feature of thought, that in them only is the form, or element contributed by mind itself, to be detected. Logic would thus be regarded as the explicit statement of the conditions of non-contradictoriness in thought, as the evolution of the formal element of thought, and since in these laws truth only as non-contradictoriness be discovered without material aid, as the theory of analytic thought. Such is the position assigned to logic by Twisten, Mansel, Spalding, and some others, and the consequences of that which inevitably leads are sufficiently interesting to require that some special attention shall be given to it. In the first place, then, it seems evident that the fundamental distinction implied, that between analytic and synthetic thought, is wrongly conceived. That analysis and synthesis are methods of cognition, differing in many important respects, is undoubted, but such difference has in a sphere altogether alien to that within which the present distinction is to be sought. Analytic thought, as here conceived, is only to be understood when taken in reference to the judgment, and then also in reference to a peculiarity in the Kantian doctrine. Kant, emphasizing the principle that judgment is essentially the form in which the particulars of experience is determined by the universal element of thought, but identifying this universal with a formal concept (resembling, therefore, a class notion), contemplated a class of judgments in which the predicate was merely an explication of the subject notion. Such judgments, had the matter been more fully considered, would have appeared as far from primary, and Kant has himself, in the most unambiguous language, indicated the correct view that analysis is consequent and dependent on synthetis,—that analytic judgments, therefore, are merely special applications of abstracting thought within a sphere already treated, handled, formed by thought. Mansel, too, whose views are generally acute if not profound, has signified as the primitive unit of cognition the so-called psychological judgment, which is essentially synthetic in character. The logical judgment, in fact, about which his conception of logic centres, as recognised as a posterior act of reflection, directed upon formal notions, and is not in any way to be regarded as containing what is a common, universal feature of all judgments.

In the second place, even granting what cannot be maintained, that the process of thought is mere explication of the content of previous knowledge, and that the theory of logic has to do with a comparatively small and subordinate portion of cognition, there is in such a principle the nucleus of development. We may take up in succession class-notions, judgments, reasonings, and in relation to each referate, as the one axiom of logic, that the consistent elements shall be non-contradictory; but such a treatment is only possible in relation to a material already formed and organized. The utmost possible value being given to such a view, logic, under it, could be but a petty and unimportant doctrine.

Finally, there is involved in the doctrine of analytic thought, and in the consequences to which extension will next be drawn, a peculiar and one-sided conception of identity or of the principle of identity as an element in thought. Historically this conception has played a most important part: it lies at the root of all nominalist

logic from Antisthenes downwards, and has found metaphysical expression of the most diverse kinds. *That things are what they are* is the old fashion in which a well-nigh forgotten English writer states what is taken to be the universal foundation of all thought and knowledge. The representatives of things in our subjective experience, the units of knowledge, may be called notions, and, accordingly, that each notion should be what it is appears as the corresponding logical axiom. The whole process of thought is therefore regarded as merely the explicit statement of what each notion is, and the separation of it by direct or indirect methods from all that it is not. The judgment, essentially the active movement of thought, is reduced to the mere expression of the identity of a notion, and in truth, were the doctrine consistently carried out, Antisthenes's conclusion that the judgment is a fallacious and inept form of thought would be the necessary result. When such a conclusion is not drawn, its place is generally taken by much vague declamation regarding the limited, imperfect, and uncertain character of our knowledge, which is regarded as asymptotically approaching to the adequate determination of truth.

The conception which underlies this view is the abstract separation of thought from things which has been already noted, but the genuine principle is a deduction therefrom. Knowledge or thought is treated externally as a series of isolated units or parts, and the results of cognition— notions, judgments, and reasonings—are viewed as the constituent factors. Thus, *e.g.*, when it is said that a judgment is the expression of an identity, there are possible only two modes of explanation,—the one, that the identity is referred to is that between the original notion (subject) as unqualified by its predicates and the same as qualified, in which case manifestly the result of the judgment is taken as being its constituent essence; the other, that the identity is that of the applicability of distinct names to the same fact, in which case we accept without further inquiry and exclude from logical consideration the processes of thought by which the application of names is brought about, and assume as being the procedure of thought itself that which is its consequence. Under all circumstances, difference is as important an element as identity in the judgment, and to concentrate attention upon the identity is to take a one-sided and imperfect view.

84. So soon, however, as the real nature of thought has been thrown out of account as not concerned in the processes of logic, so soon as the law of non-contradiction, in its manifold statement, has been formulated as the one principle of logical or formal thinking, there appears the possibility of evolving a vast system of the conditions of non-contradictoriness. The ultimate units of knowledge, whatever we call them, whether notions or ideas or classes or names, have at least one characteristic,—they are what they are, and therefore exclude from themselves whatever is contradictory of their nature. They are combined positions and negations, that which is posited or negated being left undetermined,—referred, in fact, to matter as opposed to form. With respect to any article of thought, therefore, the only logical requirement is that it shall possess the characteristic of not being self-contradictory, and the only logical question is, what exactly is posited and negated thereby. Complex articles of thought viewed in like manner as complexes of positions and negations may have the same condition demanded of them and the same question put regarding them. A judgment and a syllogism, if narrowly investigated, will appear to be merely complex articles of thought, complexes of positions and negations. Proceeding from such a conception there may be treatments more or less systematic and fruitful. In the hands of certain logicians, such as Twisten, Mansel, Spalding, and the like, little else effected, for, as the forms of thought are accepted as given and as having their characteristic otherwise fixed (by psychology or critical theory of knowledge), the treatment resolves itself either in to repetition, in respect to each, of the underlying logical condition, or into the erection of a specific kind of thought (analytical) which has no other feature save its correspondence with the said condition. But it is clear that restriction by any psychological or critical doctrine of thought is an arbitrary limitation. It is useful only to regard the operation of thought as establishment of positions and negations, and to develop, by whatever method, the systematic results of such a process. Hobbes's doctrine of thought as dealing with names and as essentially addition and subtraction of nameable features, Boole's doctrine of thought as the determination of a class, Jevons's view of thought as simple apprehension of qualities,—any of these will serve as starting point, for in all of them the fruitful element is the same. The further step that the generalization of the system of thought must take a symbolic form presents itself as an immediate and natural consequence.

85. By the application of a symbolic method is not to be understood what has been practised by many writers on logic—the illus-

¹ John Sergeant. See *The Method in Science*, by J. S., 8vo, Lond., 1868, pp. 164, 166. This curious book contains much interesting matter.

² On the difficulty of attempting to treat judgments (or equations) some excellent remarks will be found in *De Tracy, Mémoires*, iii. 182-184, cf. *De la Méthode*, i. 28-34.

tration of elementary logical relations by numerical or algebraic signs or by diagrammatic schemata. The expression has the significance which it bears in mathematical analysis, and implies that the general relations of dependence among objects of thought, of whatsoever kind, in correspondence with which operations of perfectly general character are carried out, shall be represented by symbols, the laws of which are determined by the nature of these relations or by the laws of the corresponding operations. The mere use of abbreviations for the objects of treatment is not the application of a symbolic method¹, but so soon as the general relations of, or general operations with, these objects are represented by symbols, and the laws of such symbols stated as deductions themselves, then arises the possibility of a symbolic development in method of treatment, which may lead to more or less expanded results according as the significance of the symbols is more or less general. This quantity, whether discrete or continuous, presents, as an aspect of phenomena, relations of a highly general kind, and is therefore peculiarly the subject of symbolic treatment. Currently, indeed, the treatment of quantity is assumed to have the monopoly of symbolism, but such an assumption is not self-evidently true, and it is permissible to inquire whether methods non-quantitative do not present relations of such generality that they, too, can be symbolically dealt with. It is, however, a further question whether the generality of the relations and therefore the significance of the symbols in such cases, although subject to some special conditions not necessarily involved in the nature of quantity, do not spring from the fact that we treat the matters as quantities of a special kind, and so unscrupulously find ourselves applying quantitative methods. In other words, it remains to be investigated, after the preliminary definitions and axioms of any symbolic method have been laid down, whether the conception of thought with which we start, or a special feature distinctly quantitative in character, has been the truly fruitful element in after-development of this system.²

The first step in any symbolic logic must evidently be the determination of the nature and laws of the symbols, and, as these follow from the nature and laws of operations of thought, the first step is likewise a statement of the essential characteristics of thinking. As above noted, there have been adopted various modes of expressing this characteristic, and in some cases the mode adopted is not one from which any generally applicable symbolic rules of procedure could have followed. If, on the other hand, we adopt, as representing special views, first, that which proceeds from the idea of thought as essentially the process of grouping, classing, determining a definite set of objects by a mark or notion, and second, that which proceeds more generally from the conception of thought as consisting of a series of self-identical units, to be specially determined in obedience to the law of self-identity.³ Adopting the first view, we find that processes capable of symbolic representation, by the customary algebraic signs of addition, subtraction, equivalence, multiplication, and division, have a perfectly general significance in reference to the combination, separation, equalization of classes, to the imposition and removal of relations on a class, that to the symbols there can therefore be assigned a set of general laws; and that any peculiarity of these symbolic laws which differentiates them from the laws of like symbols in mathematical analysis is detachable from the notion of thought with which we started, and is consequently to be carried along with them in all the after development. Symbolic representation of relations of classes follows with equal directness from the general notion that by any such relation a new group is determined in reference to the original groups, or rather that the position or negation of a new group (or series of groups) is given, definitely or indefinitely, as the result of such a relation.

With this aid of the symbolic laws so reached, the logical problem as such may then be approached. Given any number of logical terms (ϵ , classes, or, as it may be better put, positions and negations) connected together in any relations, to determine completely any one in reference to the others, or to express any one in terms of the others. The symbolic procedure, expounded with marvellous ingenuity and success by Boole, may take various forms, and may be simplified by many analytical devices, but consists essentially in determining systematically how given positions and negations,

definite or indefinite, combine with or neutralize one another. A more detailed account of these formal processes is beyond our limits.⁴

The first question which suggests itself in connexion with Boole's symbolic logic is the necessity or advisability of retaining the difference between classes, or the description of thought as classification. Do the symbolic laws really depend to any extent on the logical peculiarities of class arrangement? Mr. Venn, who emphasizes this feature in Boole's scheme, has, however, done good service in leading up to a different explanation. The general reference to objects, which is also noted as implied in all Boole's formulae, has nothing to do with the possible difference of conceptual or material doctrines of the proposition, and, in fact, as all distinctions of thing and quality, resemblance and difference, higher and lower, subject and predicate vanish, or are absorbed in the more general principle underlying the symbolic method, phrases such as classification, extension, intension, and the like should be banished as not pertinent. Nay, the usual distinctions of quantity and even of quality either disappear or acquire a new significance when they are brought under the scope of the new principle. "What symbolic logic works upon by preference is a system of dichotomy, of x and not x , y and not y , and so forth."⁵ In other words, quantitative differences require to find expression through some combination of the positions and negations of the elements making up the objects dealt with,⁶ while the usual qualitative distinctions are merged in the position or negation of various combinations.

The whole philosophy then of classification and its allied processes seems needless when used to denote the simple determination of objects thought. The literal signs express, not "classes," but units, determined in and for thought as self-identical. For this reason then it appears that the view of the foundations of the symbolic methods of logic taken in Grassmann's *Ergebnisse* is more thoroughgoing, and more closely represents the underlying principles, than that involved in Boole's formulae and expounded in detail by Mr. Venn.

Grassmann, as above stated, deduces logical relations as a particular case of the more general laws necessarily attending the quantities (ϵ , determined contents of thought), extracted by himself from all peculiarities which may be due to their special constitution, quantities exhibit certain formal relations when they are combined (added, subtracted, &c.). Each quantity is a unit of thought, a definite position, and of such units there are but two classes, elements and complexes. Units of thought, which are self-identical, and therefore subject to the specific law that addition of each to itself or multiplication of it by itself yields as result only the original unit, are notions. The theory of notions, therefore, is the development of the general formal conditions of units under the special restrictions imposed by their nature, by their self-identity.

There appears very clearly in Grassmann's treatment the essence of the principle on which symbolic logic proceeds. Thought is viewed as simply the process of positing and negating definite contents of units, and the operations of logic become methods for rendering explicit that which is in each case posited or negated. To apply symbolic methods, we require units as definite as those of quantitative science, and the only laws we can employ are those which spring from the nature of units as definite. Now it seems a profound error to reduce the whole complex process of thinking to this restricted position of self-identical units. Undoubtedly if we start from any given fact of thought, ϵ , ϵ , ϵ , a judgment, and inquire what can be exhibited as involved in it, we have before us a problem of analysis, the solution of which must take form in a series of positions and negations, but our thinking is not therefore as a whole more analysis. More analysis, more explicit connections of thought among the objects of our conscious experience are established is not the mechanical aggregation of elementary parts. The relations which give intelligible significance to our experience are not simply those of identity and non-identity. It is an altogether abstract and external view of thought, resting on all probability on an obscure metaphysical principle,⁷ that would treat it as in essence the composition and decomposition of elementary atoms, of ϵ , ϵ , as Anaximenes would have called them. It has, indeed, been imagined that a symbolic logic might be developed, which should be independent in all its foundations of any such metaphysical or psychological assumptions, but this is an illusion. No logical method can be developed save from a most definite conception of the essential nature and *modus operandi* of thinking, and any system of symbolic logic finds it necessary, if it is to be complete and consistent, to adopt some such view, that above criticized, to regard thought as purely analytic, as dealing with compounds or

¹ Thus one would not describe Aristotle's use of letters for the terms of his syllogisms, nor the current logical abbreviations of \mathcal{A} , \mathcal{B} , and \mathcal{M} in the case, as before, in any true sense of the word, as the application of a symbolic method. The instructive work of Mr. Venn (*Symbolic Logic*, 1881) should be consulted. Mr. Venn has not only in his title to the contrary, but he has expounded generally the character of Boole's logic with a care and skill that leave nothing to be desired, but he has, independently of any real contribution to logical analysis, put in his true light the nature of symbolic method in logic. He has rendered it impossible, even for the outsider, to complain that symbolic logic is an arbitrary application of mathematical method to logical material.

² An excellent note on symbolic logic will be found in Lotze, *Logic* (Old ed., 1880), pp. 42-48.

³ Some of these, as, ϵ , Lambert's and Peirce's, are noted and discussed by Mr. Venn (*Symbolic Logic*, xxiii.-xxviii., and *passim*).

⁴ The first is the view taken by Boole (and expounded with great fulness in Venn, as above), that the truth-bricks of logic are the *Formae* and *Modi*, 1872, especially \mathcal{B} . Die *Begriffstheorie* oder *Logik*.

⁵ Mr. Venn's work is here again irretrievable. Jevons's *Principles of Science and Studies in Deductive Logic* should be here consulted, especially the *Operational* and *Formal* chapters, which give very elegant and simple methods.

⁶ Venn, as above, p. 128.

⁷ Venn, as above, p. 128.

⁸ See Die *Begriffstheorie* oder *Logik* (1872), p. 48. Schuler (op. cit.) follows Grassmann's view with the use of class phrases.

⁹ As above noted, p. 800.

[illegible]

conclusion requires a similar analysis. See, for instance, the discussion of the fallacy of the composition in the previous section. The fallacy of the composition is grounded has been shown to fall in explaining the observed fact, the thesis may be stated in an absolute and definitive form (type 9). The remaining seven topics are then concerned with the discussion which may arise when an opponent attempts to establish the thesis by means of the fallacy of the composition. The analysis of the fallacy of the composition may be joined (type 11). Should the adversary be unable to establish his antithesis, he may resort to deceit, bringing forward arguments, illogically arranged and devoid of force (12), which soon leads to the employment of apostrophs (13) or merely apostrophs (14). The fallacy of the composition may be used to underline and signalize and discuss various well-known forms of fallacy. The destruction of all these fallacious arguments reduces the opponent to the employment of futile, irrelevant responses, which undermine his own position (15). The discourse of which completes his discourse and reduces him to silence (16).

Expositions of this dialectic system are not yet available in such kind and amount as would enable one to do full justice to it. Evidently much patience and a very considerable knowledge of the current philosophical view would be requisite in order to appreciate at their true worth many apparently formal,

and in some cases subunits, divisions. Of accounts which may be consulted and the following seem the more important—Colebrook's *Essays on the Religion and Philosophy of the Hindus*, from which the expositions in Hitter (*Op. d. Phil.*, II, 383 ff.), Hoepf (*Werk*, III, 161-167), and Cousin (*Revue Générale*, 1828, 1829), are taken; Colebrook's *History of the Religions of the Hindoos* (4 vols. 1811, later editions with title altered, in 1815, 1857, 1821); Wilschmiedman, *Philosophus im Fortgang der Weltgeschichte* (1834), especially pp. 186-190; M. Müller, appendix to Schopenhauer's *Weltanschauung* (1852), pp. 184-197; Williams, *Hindus Hindooism*, pp. 71-88; Ch. Hialat, articles "Indoent," "Göttern," "Nyaya," "Kantada," in the *Dictionnaire Philosophique*, and "Nyaya," "Nyaya," in the *Encyclopédie*, both in 1828; in the *Memoriae de rebus sanctis* of *Indica*, *Poliothes*, tom. III.

NOTE C

[illegible]

LOGOS. This term is one of the most constant factors in ancient speculation. As it is double-sided, however, expressing both *reason* and *word*, the conceptions which it covers differ widely. Taken broadly the doctrine of the Logos may be said to have run in two parallel courses—the one philosophical, the other theological; the one the development of the Logos as reason, the other the development of the Logos as word, the one Hellenic, the other Hebrew.

1. To the Greek mind, which saw in the world the *κόσμος*, it was natural to regard the world as the product of reason, and reason as the ruling principle in the world. So we find a Logos doctrine more or less prominent from the dawn of Hellenic thought to its eclipse. It rises in the realm of physical speculation, passes over into the territory of ethics and theology, and makes its way through at least three well-defined stages. These are marked off by the names of Heraclitus of Ephesus, the Stoics, and Philo.

It acquires its first importance in the theories of Heraclitus. There it is intimately associated with the dominant ideas of a flux in all things, and of fire as the material substrate or primary form of existence. On the one hand the Logos is identified with *σύνεσις* and connected with *δίκη*, which later seems to have the function of correcting deviations from the eternal law that rules in things. On the other hand it is not positively distinguished either from the ethereal fire, or from the *εὐαγέριον* and the *ἀνθρώπινον* according to which all things occur. In consistency with his hylozoic doctrine Heraclitus holds that nothing material can

be thought of without this Logos, but he does not conceive the Logos itself to be immaterial. Whether it is regarded as in any sense possessed of intelligence and consciousness is a question variously answered. But there is most to say for the negative. This Logos is not one above the world or prior to it, but in the world and inseparable from it. Man's soul is a part of it. It is *relation*, therefore, as Schleiermacher expresses it, or reason, not speech or word. And it is objective, not subjective, reason. The process of transition between opposites, in which all things are involved, is a process according to orderly relations and definite measures, and the Logos is the eternal principle of this world-process which shows itself in the form of a constant conflict between opposites. Like a law of nature, objective in the world, it gives order and regularity to the movement of things, and makes the system rational.¹

Between Heraclitus and the Stoics comparatively little was done in developing a special Logos doctrine. With Anaxagoras a conception entered which gradually triumphed over that of Heraclitus, namely, the conception of a supreme, intellectual principle, not identified with the world but independent of it. This, however, was *νοῦς*, not Logos. In the Platonic and Aristotelian systems, too, the Logos appears. But it is subordinate to other more distinctive conceptions, and lacks the definiteness of a doctrine. With Plato the term selected for the expression of the principle

¹ Cf. Schleiermacher's *Herakleitos der Dunkle*, &c.; Bernays's *Herakleitos*; Gladisch's *Herakleitos und Zoroaster*.

The Hebrew Logos and the Old Testament doctrine reach their climax in the prologue to John's Gospel. The three conceptions of the active Word, the Angel, and the Wisdom of God, which had been fused in the Rabbinical idea of a Memra, meet there in the final grandeur of the Word of God incarnate. The question of the *genesis* of the Johannine doctrine has been greatly debated. There is a remarkable similarity between John's terms and Philo's. But this is due mainly to the fact that John and Philo made use of the same inherited phraseology for the expression of their several doctrines. The Johannine doctrine is not derived from the Philonic. The Logos of Philo is distinctively reason; the Logos of John is Word. The one is metaphysical; the other is theological. In Philo the Logos is the divine principle that creates and sustains. In John the Logos who creates also redeems. In Philo the Logos hovers midway between the personal and the impersonal. In John he is a distinct personality. To Philo the idea of an incarnation of God is alien and abhorrent. The heart of John's doctrine is the historical fact that the Word was made flesh.

In many of the early Christian writers, as well as in the heterodox schools, the Logos doctrine is influenced by the Greek idea. The Syrian Gnostic Basilides held (according to Irenaeus, i. 24) that the Logos or Word emanated from the *vous*, or personified reason, as this latter emanated from the unbegotten Father. The completest type of Gnosticism, the Valentinian, regarded Wisdom as the last of the series of *aeons* that emanated from the original Being or Father, and the Logos as an emanation from the first two principles that issued from God, Reason (*vous*) and Truth. Justin Martyr, the first of the sub-apostolic fathers, taught that God produced of His own nature a rational power (*δυναμις τὴν λόγον*), His agent in creation, who now became man in Jesus (*Dial. c. Tryph.*, chap. 43, 50). He affirmed also the action of the *λόγος σπερματικός* (*Apol.* i. 46; ii. 13, 50). With Tatian (*Orat. ad. Gr.*, chap. 6, 4c.), the Logos is the beginning of the world, the reason that comes into being as the sharer of God's rational power. With Athenagoras (*Suppl.*, chap. 9, 10) He is the prototype of the world and the enengizing principle (*ἀνὰ καὶ ἐνέργεια*) of things. Theophilus (*Ad Autol.* i. 10, 24) taught that the Logos was in eternity with God as the *λόγος* in the counsel of God, and that when the world was to be created God sent forth this counsellor (*σὺμβουλος*) from Himself as the *λόγος προφορῆς*, yet so that the begotten Logos did not cease to be a part of Himself. With Hippolytus (*Refut.* x. 33, 4c.) the Logos, produced of God's own substance, is both the divine intelligence that appears in the world as the Son of God, and the idea of the universe immanent in God. The early Sabellians (comp. Euseb., *Hist. Eccl.* vi. 33; Athanas., *Contra Arian.* i. 17) held that the Logos was a faculty of God, the divine reason, immanent in God eternally, but not in distinct personality prior to the historical manifestation in Christ. Origen, referring the act of creation to eternity instead of to time, affirmed the eternal personal existence of the Logos. In relation to God this Logos of Son was a copy of the original, and as such inferior to it. In relation to the world he was its prototype, the *ἀνὰ θεόν*, and its redeeming power (*Contra Cel.* v. 606; *Prag. de Princip.* i. 4; *De Princip.* i. 109, 824).

Literature.—In addition to the histories of philosophy (e.g., those of Hübner, Overweg, Zeller, &c.), the commentaries on John's Gospel (Müller, Godes, Wüst, &c.), and the systems of Biblical theology (Oschler, Schultze, Hauser, &c.), the following writings deserve special notice.—Schleier, *Lehrb. der N-T. Zeugnisschichte*; Hauser, *Neu-Testamentliche Zeugnisschichte*; Helmke, *Lehre vom Logos in der griechischen Philosophie*; Schultze, *Die Doctrina de Logos*; Hilgen, *Philos. Begriff*; Philo: Deussen, *Geschichtliche Darstellung der Jüdisch-alexandrinischen Religions-Philosophie*; Dörner, *History of the Development of the Doctrine of the Son of God*; Raben, *Philosophische Kirchenlehre*; Weber, *System der Abhängigen und Selbständigen Theologien*; Gromann, *Quantitative Philosophie*. (S. D. F. S.)

LOGROÑO, an inland province of Spain, the smallest of the eight modern divisions of Old Castile, is bounded on the N. by Burgos, Alava, and Navarra, on the E. by Navarra and Zaragoza, on the S. by Soria, and on the W. by Burgos. The area is 1945 square miles, with a population in 1877 of 174,425. It belongs entirely to the basin of the river Ebro, which forms its northern boundary except for a short distance near San Vicente, and is now navigable throughout the entire length of the province; its drainage takes place chiefly by the rivers Tiron, Oja, Najerilla, Iregua, Lea, Cidacos, and Alhama, all flowing in a north-easterly direction. The portion skirting the

Ebro forms a spacious and for the most part fertile undulating plain, called La Rioja in its western part; but in the south Logroño is considerably broken up by offshoots from the sierras which separate that river from the Douro. In the east the Cerro de Lorenzo rises to a height of about 7725 feet, and in the south the Pico Santa Ines is upwards of 7380 feet. The mineral resources, which are believed to be considerable, are as yet undeveloped. The products of the province are chiefly cereals, good oil and wine (especially in the Rioja), fruit (except oranges and lemons), silk, flax, and honey. The industries, which are unimportant, include spinning and weaving. Logroño is traversed by the Ebro valley railway, which connects Miranda del Ebro with Zaragoza; on this line are situated all the towns of the province with a population exceeding 5000—Haro, Logroño, Calahorra, and Alfaro.

LOGROÑO, capital of the above province, is situated on the right bank of the Ebro, which is here crossed by a handsome stone bridge of twelve arches, dating from 1138; the surrounding plain is well cultivated and fertile, producing the rich Rioja wine. The city is the seat of the usual provincial authorities, civil and military. It has a theatre, and several hospitals and convents. The parish church claims great antiquity. The population in 1877 was 13,393; the trade and industries are unimportant.

The district of Logroño was in ancient times inhabited by the *Berones* or *Vorones* of Strabo and Piny, and their *Varia* is to be identified with the modern suburb of the city of Logroño now known as *Varea* or *Barea*. The place fell into the hands of the Moors in the 8th century, but was speedily retaken by the Christians, and under the name of *Lucenonis* appears with frequency in mediæval history. Logroño was the birthplace of the painter Navarrete (d. 1610) and of Espartaco; the latter died there on January 9, 1678.

LOGWOOD is a valuable dye-wood, the product of a leguminous tree, *Hæmatoxylon campechianum*, native of Central America, and grown also in the West Indian Islands. The tree attains a height not exceeding 40 feet, and is said to be ready for felling when about ten years old. The wood, deprived of its bark and the sap-wood, is sent into the market in the form of large blocks and billets. It is very hard and dense, and externally has a dark brownish-red colour, but it is less deeply coloured within. The best qualities come from Campeachy, but it is obtained there only in small quantity. A large export trade in logwood of good quality is carried on from Honduras and Jamaica, and inferior qualities are exported from St Domingo, Martinique, Guadaloupe, &c. The wood was introduced into Europe as a dyeing substance soon after the discovery of America, but for many years (from 1881 to 1863) its use in England was prohibited by legislative enactment on account of the inferior dyes which at first were produced by its employment.

The colouring principle of logwood exists in the timber in the form of a glucoside, from which it is liberated as hæmatoxylin or hæmatin by fermentation. Hæmatoxylin was first isolated by Obernal in 1810, and its constitution was subsequently investigated by Erdmann, who found it to have the formula $C_{14}H_{11}O_6$. It forms two crystalline hydrates, the principal combination being with three molecules of water. This hydrate, $C_{14}H_{11}O_6 \cdot 3H_2O$, is a colourless body very sparingly soluble in cold water, but dissolving freely in hot water and in alcohol. By exposure to the air, especially in alkaline solutions, hæmatoxylin is rapidly oxidized into hæmatin, with the development of a fine purple colour. The reaction consists in the elimination of two atoms of hydrogen, thus—hæmatoxylin hydrate $(C_{14}H_{11}O_6 \cdot 3H_2O) + O =$ hæmatin $(C_{14}H_9O_6 \cdot 3H_2O) + H_2O$. This reaction of hæmatoxylin is exceedingly rapid and delicate, rendering that body a valuable laboratory test for alkalis. It is remarkable that the difference of two atoms of hydrogen between colourless hæmatoxylin and coloured hæmatin is precisely that which exists between the white and the blue forms of indigo. By the action of hydrogen and sulphurous acid, hæmatin is easily reduced to hæmatoxylin.

Logwood is prepared for use by dyers, &c., in the form of chips and raspings, and as a solid brittle black extract. Chipped logwood is moistened with water and spread in thin layers till a gentle fermentation sets up, whereby, under the influence of liberated ammonia, hematoxylin is formed from the glucoside. By exposure to the air, through repeated turnings of the mass, hematein is developed from the hematoxylin, and the chips gradually become coated with the brilliant metallic green crystals of hematein. Logwood extract, largely used in calico printing, is obtained from exhausted chips and raspings by lixiviation, the solution being concentrated at as low a temperature as possible.

The principal use of logwood is for dyeing wool and woollen goods, on which it produces, with various mordants, shades of blue from a light lavender to a dense blue-black, according to the amount of logwood used. It is more employed in combination with other dye-stuffs than as the sole tintorial agent, the best and most permanent blacks on wool, known as woaded blacks, being first dyed blue in the indigo vat, and finished black with logwood and bichromate of potash. In calico-printing logwood is used to produce steam purple, for the production of which the calico is mordanted with stannate of soda, and printed with a strong solution of logwood extract thickened with starch. By steaming, the hematein of the logwood combines with binoxide of tin precipitated in the fibre, and thus develops a bright purple colour. Logwood blacks, which are a standard product of print works, are produced by mordanting with iron liquor, passing the calico through a logwood solution, and developing and fixing the colour by treatment with a weak solution of bichromate of potash. Logwood blacks assume a bright red tint by the action of dilute acids, a test by which they can readily be distinguished from aniline and other fast blacks. Logwood is also largely used in the preparation of Inx (qn) , and to a small extent in medicine. The imports of logwood into the United Kingdom during the year 1880 amounted to 62,280 tons, the estimated value of which was £192,392.

LOHARDAGA, or **LOHARDUGA**, a district in the lieutenant-governorship of Bengal, India, between 23° 20' and 24° 39' N. lat. and 85° 22' and 85° 58' E. long., is bounded on the N. by Hazaribagh and Gaya, on the N.W. and W. by Mirzapur district and Sargodhā and Jashpur states, and on the S.E. and E. by Singhbhum and Manbhum districts. It comprises Chutia Nāgpur proper, and the Palāmau subdivision. Chutia Nāgpur is an elevated table-land, forming the central and south-eastern portion of Lohardāgā district; its surface is undulating, and the slopes of the depressions lying between the ridges are cut into terraces covered with rice. Palāmau, which forms the north-western portion of the district, consists on the east and south of spurs thrown off from the plateaus of Hazaribagh and Chutia Nāgpur, while the remainder of the tract is a tangled mass of isolated peaks and long irregular stretches of broken hills. The average elevation of Palāmau is about 1200 feet above sea-level, but some peaks rise to over 3000 feet. This part of the district contains no level areas of any extent, except the valleys of the North Koel and Amlānt rivers, to which rice cultivation is confined. The principal rivers of Lohardāgā are the Subarnarekhā and the North and South Koel. The entire district was probably at one time overgrown with dense forest, but the forest area has been continually dwindling, owing to the spread of cultivation and the practice of girdling the *sal* trees for resin.

The census of 1872 disclosed a total population of 1,287,138 (631,549 males and 655,579 females), spread over an area of 12,044 square miles; of these only 81 were returned as Europeans and 8 as of mixed race. The aboriginal element is very strongly represented—the Mundas numbering 169,051; Kols, 132,104; and Uraons, 171,810. The most numerous among the semi-aboriginal tribes are—the Bhuiyās, 46,008; Khawās, 33,678; Bhogtās, 33,432; and Desdās, 26,228. The Hindu number 741,962, and the Mohammedans 83,811. The Christian population is larger than in any other Bengal district, except the metropolitan one of the

Twenty-four Parganas. In 1873 the total Christian population numbered 12,781, of whom 12,667 were natives, nearly all belonging to the aboriginal tribes of Mundas and Uraons. Most of them are poor, but they possess considerable influence, and are rising in public esteem. The two missions are the German Lutheran and Church of England, which successfully work together and by aid.

The population is entirely rural, Ranchi town (12,086) being the only place with more than 5000 inhabitants. Rice forms the staple crop; other crops are wheat, barley, Indian corn, millets, peas, gram, chickpeas, *pada*, cotton, and tobacco. Opium cultivation was introduced in 1869, and in 1874-75 yielded 245 cwts. There are two small tea plantations. Mildew and blights occasionally attack the crops; droughts seldom affect any considerable area. The principal trading places are Garwa in Palāmau. Stock lac, *tesu*, catechu, silk cocoons, hides, oil-seeds, *ghā*, cotton, and rice are here collected for exportation, while rice and other food grains, brass vessels, piece goods, blankets, broad cloth, silk, salt, tobacco, spices, drugs, and beads are brought to market for local consumption. The manufactures consist of shell-lac, inferior articles of brass and iron work, coarse cloth, blankets, mats, baskets, rope, and rude pottery. Iron, lime, and soapstone are worked in small quantities; gold is washed by the poorer classes from the sands of the rivers. An important coal-bearing tract, known as the Daltonganj coal-field, covers an area of nearly 200 square miles, and lies partly in the valley of the Koel river, and partly in that of the Amlānt. The net revenue of the district in 1879-80 was £103,940, and the expenditure £22,463. The population in 1878-79 numbered 908,347 with 8088 villages. The climate of the table-land of Chutia Nāgpur is said to be superior to that of any other part of India, except the lower ranges of the Himalayas. The hot weather extends over almost six weeks, commencing about the 20th April, but is never really oppressive. The rainy season lasts from the middle of June to about the first week in October. The principal diseases are malarious fever and rheumatism of a severe type.

LOIRE (Lat., *Liger*), the first of the rivers of France in length of course (836 miles) and extent of basin (14,079 square miles), has its headwaters in the great central plateau, and is considered to take its rise in the Clercier de Jone, in the department of Ardèche, at a height of 4604 feet above the sea,—though the Allier branch, which has its source about 30 miles west, in the department of Lozère, at the foot of Maure de la Gardille, 4093 feet above the sea, has an almost equal course. The two streams continue to run parallel till the upper Loire turns westward and is joined by the Allier in the neighbourhood of Nevers. All the more important affluents of the upper and middle part of the Loire—as the Cher, the Indre, the Vienne, respectively 198, 162, and 231 miles in length—have their gathering grounds in the central plateau. In the north-east the basin of the Seine comes so close (at one place to within 6 or 7 miles) that the versant towards the Loire has hardly anything to contribute; and it is not till within 65 miles of the estuary that we find an important tributary, the Maine, bringing down the drainage of the Brittany plateau. At certain seasons the Loire is navigable for ships as far as Nantes (33 miles), for boats as far as La Noire (other 618 miles), and for rafts as far as Retournac; but for six months of the year navigation is practically impossible.

In the volume of water there is all the irregularity of a mountain torrent, at the Boc d'Allier, for instance,—the meeting point of the two head streams,—while the maximum current is 353,200 cubic feet per second, the minimum is 10,800 cubic feet, and above Orleans the range lies between 81,800 and 650. During the drought a slender thin and feeble stream threads their way between the sandbanks of the channel, while at other times a stupendous flood pours down and submerges wide reaches of land. In the middle part of its course the Loire traverses the western portion of the undulating Paris basin, with its Tertiary marls, sands, and clays, and the alluvium carried off from these renders its lower channel incognitum, the rest of the drainage area is occupied by crystalline rocks, over the hard surface of which the water, undiminished by absorption, flows rapidly into the streams. A fall of from 3 to 4 inches over the whole river basin is sufficient to pour 35,320,000,000 cubic feet of water into the channels. When the rain is general over the whole area, the floods on the different branches reach the main river at different times; but when, through any cause, two or more of them arrive at the same time, inundations of the most serious character result. Attempts to control the river must have begun at a very early date, and by the close of the Middle Ages the bed between Orleans and Angers was enclosed by dykes 10 to 12 feet high. In

1753 a double line of dykes or *turres* 23 feet high was completed from Bec d'Allier downwards. This great work had, however, the serious defect that the channel was so much narrowed that the embankments are almost certain to give way as soon as the water rises 16 feet (the average rise is about 14, and in 1846 it was more than 23). In more modern times the importance of the water-way from the sea to Nantes led to the embanking of the lower part of the course; but instead of a depth of 10 feet, being secured, as the engineers anticipated, there is no more at full tide than 13 feet. One of the practical results of the state of matters has been the commercial development of Saint Nazaire and Paimboeuf, and the comparative decline of Nantes as a great shipping port. Best of all, the general embankments of the river, several of the towns along the Loire have constructed special works to defend themselves against the floods; Tours, the most exposed of all, is surrounded by a circular dyke. Various schemes for the systematic regulation of the Loire have been discussed. It has been proposed to construct in the upper valleys of the several affluents a number of granite dams or reservoirs from which the water, stored during flood, could be let off into the river as required. A reservoir of this kind, formed by the engineer Mathieu at the village of Pissay, about 15 miles above Roanne, and capable of retaining from 8500 to 4500 million cubic feet of water, has greatly diminished the force of the floods at Roanne, and maintained the comparative equilibrium of the current during the dry season. There is a canal (167 miles) along the left bank of the Loire between Roanne and Briare, and the Canal du Berry connects this with the navigable part of the Cher. The Canal du Centre extends from Digoin on the Loire to Chalon on the Saône; the Canal du Nivernais and the canals starting from Orleans and Briare communicate with the Seine; and the Nantes canal opens up the way to Lorent, Brest, and Dinan. The canals of the Saône and the Dure (20 and 28 miles respectively) are mainly for irrigation purposes.

See H. Bierry, *Tourisme, Jeunes, et canaux de la France* (Paris, 1878), and his papers in *Rev. des Deux Mondes*, February and March 1875.

LOIRE, a department of central France, made up of the old district of Forez and portions of Beaujolais and Lyonnais, all formerly included in the province of Lyonnais, lies between 45° 16' and 46° 15' N. lat. and between 3° 40' and 4° 45' E. long., and is bounded on the N. by the department of Rhône-et-Loire, on the E. by those of Rhône and Isère, on the S. by Ardèche and Haute-Loire, and on the W. by Puy de Dôme and Allier. Its extreme length is 78 miles from north-west to south-east, and its extreme breadth from east to west is about 43 miles, the area being 1838 square miles. Until 1790 it constituted a single department along with that of Rhône. About an eighth part of the whole area belongs to the basin of the Rhône. The Loire, which has a fall within the department from 1365 feet to 886 feet, traverses alternately a series of narrow gorges and of broad plains, the beds of ancient lakes, including that of Forez between St Rambert and Feurs, and, lower down, that of Roanne. Of its affluents the most important are the Lignon du Nord, the beautiful valley of which has been called "La Suisse Forezienne," and the Ais on the left, and on the right the Oudaine (on which stand the industrial towns of Chambon-Fegerolles and Firminy), the Furens, and the Rhin. To the Rhone the department contributes the Gier, upon which are situated the industrial towns of St Chamond and Rive de Gier, and which forms a navigable channel to the Rhone at Givors. From Mont Pilat descends the Dôme, in the valley of which the workshops of Annonay begin. In the west are the Forez mountains, which separate the Loire basin from that of the Allier; their highest point (Pierre sur Haute, 5381 feet) is 12 miles west from Montbrison. They sink gradually towards the north, and are successively called Bois Noirs (4239 feet), from their woods, and Monte de la Madeleine (3800 to 1640 feet). In the east the Rhone and Loire basins are separated by Mont Pilat (4705 feet) at the north extremity of the Cévennes, and by the hills of Lyonnaise, Tarare, Beaujolais, and Charolais, none of which rise higher than 2950 or 3280 feet. The climate of the department varies according to the elevation: on the heights it is cold and healthy, unwholesome in the marshy plain of Forez, mild in the valley of the Rhone. The

annual rainfall is 39 37 inches on the Forez mountains, but only 24.79 at Roanne. More than half of the area consists of arable lands; one-seventh is occupied by forests, and one-seventh by meadows.

The plains of Forez and Roanne are the two most important agricultural districts, but the total production of grain within the department is insufficient for the requirements of the population. The pasture lands of Forez support a large number of horned cattle, sheep, goats, and pigs. Fairly good red wine is also grown within the department; potatoes, leguminous plants, beetroot, hemp, and colza are also cultivated. Forestry are reared, and bee-keeping is a considerable industry. Among the hills replantation has been set on foot. The Bois d'Or forest yield good-sized pines and large quantities of wood for mining purposes. The so-called Lyons chestnuts are to a large extent obtained from Forez; the woods and pasture lands of Fiat yield medicinal plants, such as mint. The chief wealth of the department, however, lies in the coal deposits in the St Etienne basin, the second in importance in France. The basin, which stretches from south-west to north-east between Firminy and Rive de Gier, is about 20 miles in length and 6 in breadth. In 1881 the output amounted to 3,454,612 tons of coal and anthracite, giving employment to 12,000 workmen below and 5000 above. The presence of coal has naturally encouraged various forms of the metal-working industries. At St Etienne there is a national factory of arms, in which as many as 6000 have been employed; apart from other factories of the same kind carried on by private individuals, the production of hardware occupies 7000 persons, locks, common cutlery, chain cables for the mines, files, and nails are also made. Cast steel is largely manufactured, the aggregate production of all sorts of steel amounting in 1880 to 114,029 tons; the Loire workshops supply the heaviest constructions required in naval architecture. The glass industry has its centre at Rive de Gier. St Etienne employs more than 50,000 persons in the fabrication of silk ribbons, to an annual value of £4,000,000; over and above this must be reckoned the manufacture of elastic ribbons and laces, and the dressing of raw silk. The armament of Roanne manufactures cotton goods, has over 11,000 looms, each employing three persons. That of Nagnat produces table linen. In the mountains between Haute-Loire and Puy de Dôme the women make black laces and embroidery. The department has numerous flour-mills, paper works, tanneries, boat-building yards, silk-spinning works, and velvet, plush, and hat factories. There are three arrondissements—St Etienne, Montbrison, and Roanne. The capital is St Etienne. The population, 290,908 in 1801, was 590,618 in 1876.

LOIRE, HAUTE-, a department of central France, made up of Velay and portions of Vivarais and Gévaudan, three districts formerly belonging to the old province of Languedoc, of a portion of Forez formerly belonging to Lyonnais, and of a portion of lower Auvergne, is bounded on the N. by Puy de Dôme and Loire, on the E. by Loire and Ardèche, on the S. by Ardèche and Lozère, and on the W. by Lozère and Cantal, and lies between 44° 40' and 46° 25' N. lat. and between 3° 5' and 4° 30' E. long., having an extreme length of 68 miles, a maximum breadth of 54 miles, and an area of 1916 miles. It belongs almost wholly to the Loire basin, but a few square kilometres to the north of Mont Mézenc are drained by the Erioux, a tributary of the Rhone. The highest point, Mont Mézenc, on the borders of Ardèche, is 8745 feet; it belongs to the Cévennes system, which sends ramifications throughout the entire department, giving it a mean altitude of 2950 feet. Reckoning from east to west are the Boutières, the Mègal or Meygal, the Velay hills, those of La Marguerite, and finally the Lugnet. The first mentioned ridge separates Haute-Loire from Ardèche, and ranges from 3280 to 4590 feet; it has a crust of lava thrown out from Mont Mézenc; efforts towards replantation are being made. Meygal presents a series of jagged peaks, recalling the Pyrenees on a small scale. It also has been covered by an immense flow of lava some 37 miles long and 490 feet thick, through which the Loire has forced a passage by means of gorges more than 1600 feet in depth. The highest point of the Meygal properly so called is upwards of 4590 feet. The Velay hills, which separate the Loire from the Allier (mean height about 3300 feet), consist of granitic rocks overlaid with the eruptions of more than one hundred and fifty craters, one of which

is now occupied by the singular lake of Bouchet. Westward from the Allier are the forest-clad granitic hills of La Marguerite, which rise to a height of nearly 5000 feet. The Lugnet massif (3500 feet) rises in the north-west of the department on the left bank of the Allagnon, a tributary of the Allier. The river Loire, to which the department owes its name, enters at a point 16 miles distant from its source, and 2923 feet above the level of the sea. Within the 63 miles of its course through the eastern portion of the department, first in a northerly and afterwards in a north-easterly direction, it falls 1655 feet. The Allier, which joins the Loire at Nevers, traverses the western portion of Haute-Loire in a northerly direction, entering at a point 25 miles distant from its source, and 2369 feet above the sea; it traverses a narrow and deep valley overlying by lofty hills, and falls 1090 feet. The chief affluents of the Loire within the limits of the department are the Borne on the left, joining it near Puy, and the Lugnet, which descends from the Mézère, between the Bouchères and Moygny ranges, on the right. The climate, owing to the altitude, the northward direction of the valleys, and the winds from the Cévennes, is cold, the winters being long and rigorous. Storms and violent rains are frequent on the higher grounds, and would give rise to serious inundations were not the rivers for the most part confined within deep rocky channels. Two-fifths of the area is occupied by arable lands, one-fifth by natural meadow and by orchards, and a somewhat smaller proportion by wood. The rest consists of pasture lands, vineyards, and uncultivated lands.

Numerous cattle of the celebrated Mézère breed are reared, and also sheep and mules. The crops raised are wheat, maiz, rye, barley, oats, maize, potatoes (in large quantities), hemp, clover, and second-class wares. The woods yield jun, fir, oak, and beech. Large quantities of aromatic and pharmaceutical plants are found in the Mézère massif. The department has two coal basins, those of Brassac and Lengons, both on the Allier; in 1880 their total output was 225,153 tons. Copper, iron, zinc, argentiferous lead, granite, antimony, barytes, and fluor spar are also obtained, and there are good quarries of trachyte and limestone, as well as numerous unutilized mineral springs. Lace-making in various materials is the most extensive industry, occupying from 150,000 to 180,000 persons, and producing goods to the annual value of about 41,000,000. Ribbons and cloth are manufactured to some extent, and silk-dyeing, wool-spinning, cotton-weaving, various kinds of smith work, paper-making, glass-blowing, brewing, wood-sawing, and flour-milling are also carried on. There are three arrondissements—Puy, Bilande, and Yssingeaux; the capital is Puy. The population in 1876 was 318,721.

LOIRE-INFÉRIEURE, a maritime department of western France, is made up of a portion of Brittany on the right and of the district of Retz on the left of the Loire, and lies between 46° 45' and 47° 40' N. lat. and between 55° and 2° 33' W. long., being bounded on the W. by the ocean, on the N. by Morbihan and Ille-et-Vilaine, on the E. by Maine-et-Loire, and on the S. by Vendée. Its greatest length from east to west is 76 miles, its greatest breadth 65 miles, and its area 2654 square miles. The surface is very flat, and the highest point, in the north on the borders of Ille-et-Vilaine, is only 377 feet. The line of hills skirting the right bank of the Loire, and known as the "sillon de Bretagne," nowhere attains a height of 265 feet; below Savennay they recede from the river, and the meadows give place to peat bogs. North of St Nazaire the Grande Brière, measuring 9 miles by 6, and rising scarcely 10 feet above the sea-level, still supplies old trees which can be used for joiner work; a few scattered villages occur on the more elevated spots, but communication is effected chiefly by means of the canals which intersect it. The district on the south of the Loire lies equally low; its most salient feature is the lake of Grandlien, covering an area of 27 square miles, and surrounded by low and marshy ground, but so shallow (5·5 feet at most) that

drainage would be comparatively easy. The Loire has a course of 68 miles within the department, its width above Nantes varies from 1300 to 3280 feet, and its volume at Nantes, where the tide begins to be felt, is never under 700 cubic metres per second. It has numerous islands. At Paimboeuf it is nearly 2 miles broad, but narrows again opposite St Nazaire before finally entering the ocean. The bed is not sufficiently regular to allow easily the passage of vessels drawing more than 10 feet of water. On the left bank a canal of 9 miles is about to be opened between Fellerin, where the dikes which protect the Loire valley from inundation terminate, and Paimboeuf. The principal towns on the river within the department are Ancenis, Nantes, and St Nazaire (one of the most important commercial ports of France) on the right, and Paimboeuf on the left. The chief affluents are on the right the Erdre and on the left the Sèvre, both debouching at Nantes. The Erdre has a succession of broad lakes which give it the appearance of a first class river, it forms part of the canal from Nantes to Brest. The Sèvre, on the other hand, is hemmed in by picturesque hills, at the point where it enters the department it flows past the famous castle of Clisson. Apart from the Loire itself, the only navigable channel of importance within the department is the Nantes and Brest canal already referred to, fed by the Isac, a tributary of the Vilaine, which separates Loire-Inférieure from Ille-et-Vilaine and Morbihan. The climate partakes of the general Armorican character in respect of humidity, but is Girondine in its mildness. At Nantes the mean annual temperature is 54° 7 Fahr., and there are one hundred and twenty-two rainy days, the annual rainfall being 25·6 inches. Of the entire area nearly two-thirds is arable, one-seventh is occupied by meadows; and vineyards, woods, heath, lakes, pools, and marshes occupy the remainder.

The quantity of live stock is considerable—820,000 horned cattle, 180,000 sheep, 80,000 pigs, 38,000 horses, asses, and mules. Industry also is varied, and there is a good deal of bee-keeping. Wheat, rye, buckwheat, oats, and clover are produced in great abundance, leguminous plants are also largely cultivated, especially near Nantes. Beetroot, hemp, and chestnuts represent, along with wine and cider, the chief remaining agricultural products. The woods are of oak in the interior and pine on the coast. The department has deposits of tin, lead, and iron, which are hardly wrought, if at all. North-west from Ancenis a little antimony is obtained from a coal-bed which is a prolongation of that of Anjou. The salt marshes, about 6000 acres in all, occur for the most part between the mouth of the Vilaine and the Loire, and on the Bay of Bourgneuf. The salt manufacture, which as late as 1874 produced 48,475 tons, is now decaying. There are also quarries in the north-east of the department, and the granite of the sea-coast and of the Loire up to Nantes is quarried for large blocks, while the limestone about Châteaubriant occupies numerous kilns. The industries of the department are well developed. Steam-engines are built for Government at Indret, a few miles beyond Nantes; the forges of Basse-Indre are in good requis for the quality of their iron; and the production of the lead-smelting works at Concarneau amounts to several millions of francs annually. There are also considerable foundries at Nantes, Chantenay, and St Nazaire, and shipbuilding yards at Nantes, St Nazaire, Paimboeuf, and Grand. Among other industries may be mentioned the preparation of pickles and preserved meats at Nantes, the curing of salmon at Cholet and in the neighbouring communes, salt-reining, the great sugar refinery at Nantes, and the tobacco manufacture also there. Fishing is prosecuted along the entire coast. Nantes, formerly one of the most important of French ports, has now given way before St Nazaire, the trade of which in 1878 exceeded 1,500,000 tons. The principal imports are coal, colonial wares, wood, metals, manure; the exports are wine, salt, preserved meats and pickles, flour, refined sugar, and butter. The department is divided into five arrondissements—Nantes, Ancenis, Châteaubriant, Paimboeuf, and St Nazaire; Nantes is the capital. The population in 1876 was 612,972, an increase of 243,657 since 1801.

LOIRET, a department of central France, made up of three districts of the ancient province of Orléanaise,—Orléanaise proper, Gâtinais, and Dunois,—together with portions of the Isle of France and Berri, lies between

47° 30' and 48° 30' N. lat. and between 1° 30' and 3° 8' E. long., and is bounded on the N. by Seine-et-Oise, on the N.E. by Seine-et-Marne, on the E. by Yonne, on the S. by Nièvre and Cher, on the S.W. by Loire-et-Cher, and on the N.W. by Eure-et-Loir, its greatest length, from north-west to south-east, is 75 miles, its greatest breadth, from north to south along the meridian of Paris, 60 miles, and its area 2614 square miles. The name is derived from the Loire, a stream which issues from the ground some miles to the south of Orleans, and after a course of about 7 miles falls into the Loire; its large volume gives rise to the belief that it is a subterranean branch of that river. The Loire traverses the department by a broad valley which, though frequently devastated by disastrous floods, is famed for its rich tilled lands, its castles, its towns, and its vine-clad slopes. To the right of the Loire are Gâtinais (capital Montargis) and Beauce, the former district is so named from its *gâtines* or wildernesses, of which saffron is, along with honey, the most noteworthy product; Beauce, on the other hand, a monotonous tract of corn-fields without either tree or river, has been called the granary of France. Between Beauce and the Loire is the extensive forest of Orleans, which is slowly disappearing before the advances of agriculture. South of the Loire is Sologne, long barren and unhealthy from the impermeability of its subsoil, but undergoing gradual improvement in both respects by means of pine plantation and draining and manuring operations. The surface of the department presents little variation of level, the highest point (on the borders of Cher) is 900 feet above the level of the sea, and the lowest (on the borders of Seine-et-Marne) is 220 feet. The watershed on the plateau of Orleans between the basins of the Seine and Loire, which divide Loiret almost equally between them, is almost imperceptible. The lateral canal of the Loire from Roanne stops at Briare; from the latter town a canal connects with the Seine by the Loing valley, which is joined by the Orleans canal at Montargis. The only important tributary of the Loire within the department is the Loiret, the Loing, a tributary of the Seine, has a course of 40 miles from south to north, and is accompanied throughout first by the Briare canal and afterwards by that of Loing. The Essonne, another important affluent of the Seine, entering Loiret at Maleherbes, takes its rise on the plateau of Orleans, as also does its tributary the Juine. The department has the climate of the Sequanian region, the mean temperature being almost the same as that of Paris; the number of rainy days is one hundred and twenty, and the rainfall varies from 18½ to 27½ inches according to the district, that of the exposed Beauce being smaller than that of the woody Sologne. Two-thirds of the entire area is cultivable; between one-sixth and one-seventh is under wood; vineyards occupy one-twentieth, and the remainder is taken up by meadows, heath, and marsh.

A large number of cattle, sheep, asses, pigs, and goats are reared; poultry, especially geese, and bees are plentiful. The yield of wheat and oats is much in excess of the consumption, the crops of rye, barley, meslin, potatoes, bestroot, colza, and hemp are also very important. Wine is abundant, but of inferior quality. Buckwheat supports bees by its flowers, and poultry by its seeds. Saffron is another source of wealth. The woods consist of oak, elm, birch, and pine; fruit trees thrive in the department, and Orleans is a great centre of nursery gardens. The industries are brick and tile making, and the manufacture of fustice, for which Chen is one of the most important centres in France. The Briare manufacture of porcelain bottoms and necks employs 1500 workmen. Flour-mills are very numerous. There are iron and brass foundries, which, along with agricultural implement making, bell-founding, and the manufacture of pins, needles, and files, represent the chief metal-working industries. The production of hosiery, wool-spinning, and various forms of wool manufacture are also engaged in. A large quantity of the wine grown is made into vinegar (*vin deigre* d'Orleans). The tanneries produce excellent leather; and paper-making, sugar-refining, wax-blessing, and the manufacture of acetone (in one factory) complete the list of industries. The exports are principally

corn, flour, wine, vinegar, live-stock, and wool. The four arrondissements are those of Orleans, Chen, Montargis, and Fichault. The capital is Orleans. The population in 1876 was 360,903, an increase of 70,764 since 1861.

LOIR-ET-CHER, a department of central France, consists of a small portion of Touraine, but chiefly of portions of Orléanais proper, Bloisais, and Dunois, districts which themselves formerly belonged to Orléanais. It lies between 47° 11' and 48° 8' N. lat. and between 0° 36' and 2° 15' E. long., and is bounded on the N. by Eure-et-Loir, on the N.E. by Loiret, on the S.E. by Cher, on the S. by Indre, on the S.W. by Indre-et-Loire, and on the N.W. by Sarthe, the greatest length (north-west to south-east) being 78 miles, maximum breadth 31 miles, and the area 2452 miles. Its name is derived from the Loir and the Cher, by which it is traversed in the north and in the south respectively. The Loir divides it into two nearly equal portions, the district on the right of the Loir being known as Beauce, while that on the right of the Loir again is called Perche, on the left of the Loir is Sologne. The surface of Perche is raised, and reaches a maximum height of 840 feet, its woods alternate with hedged fields and orchards, and rapid rivulets water the green valleys. Beauce is a rich agricultural country, where the monotony of the endless fields of corn is broken only by the houses grouped together in villages, or by the stacks which surround them. Sologne was formerly a region of forests, of which that of Chambord is one of the last remains. Its soil, formerly barren and unhealthy, has been considerably improved within recent years. The Cher and Loir traverse pleasant valleys, occasionally bounded by walls of tufa, in which numerous dwellings have been excavated; the stone extracted, after hardening by exposure to the air, has been used for building purposes in the nearer towns. Within the department the Loir has a course of 66 miles, the Cher of 50, and the Loire of 37. With the help of the Briare canal the last-mentioned is navigable throughout. The chief remaining rivers of the department are the Beuvron, which flows into the Loire on the left, and the Sauldre on the right of the Cher. All these named have a south-westerly course, following the slope of the department. The climate is temperate and mild, and healthy if Sologne be left out of account. The mean temperature ranges between 52° and 53° Fahr., and the rainfall is 25½ inches. Of the total area more than a half is arable, one-sixth is under wood, and one-sixth is waste; vineyards, meadows, and pasture lands occupy the remainder.

Sheep are extensively reared, and the Perche breed of horses is much sought after for its combination of lightness with strength. There are more than twenty thousand beehives within the department. Beauce is the most productive district; in 1876 it yielded 543,000 quarters of wheat, 556,000 of oats, and 1,600,000 bushels of potatoes, beans, meslin, rye, barley, buckwheat, bestroot, maize, colza, and hemp. In the same year the production of wine amounted to 27,000,000 gallons, the most valuable being that of Chen du Cher. The forests are an important source of wealth. Sologne supplies pine and birchwood for furnace fuel, and in the neighbourhood of Blois there are oak, elm, and chestnut plantations. In the river valleys fruit trees and nursery gardens are numerous. Formerly the speciality of Loir-et-Cher was to supply Europe with gun flint. Building stones, and also clay for bricks and pottery, are also abundant. The chief industries are the manufacture of cloth at Romorantin (where spinning, ribbon-making, and tanning are also carried on), of white leather and gloves at Vendôme, distilling, glass-making, paper-making, pottery-making, and the like. The exports are wine, branly, vinegar, wood, cloth, wool, leather, grain, legumes, wax, and lard. Of the castles which adorn the department the finest and most famous is that of Chambord, near the left bank of the Loire opposite Blois (the capital). The three arrondissements are those of Blois, Romorantin, and Vendôme. In 1876 the population was 272,684, an increase of 55,721 since 1861.

LOJA, or LOXA, a town of Spain, in the province of Granada, lies in a beautiful valley through which flows the Genil, here crossed by a Moorish bridge, about 33 miles

by rail west from Granada. The situation is very steep, and the streets in consequence are extremely crooked and irregular. The castle stands on a rock in the centre of the town, which, from being the key to Granada, was once a place of great military importance. The manufactures of Loja consist chiefly of coarse woollens, silk, paper, and leather. Salt is obtained in the neighbourhood. The population in 1877 was 18,249.

Loja, which has sometimes been identified with the ancient *Tipula*, or with the *Lozeta* (*Lozeta*) of Ptolemy, first clearly emerges in the Arab chronicles of the year 890. It was taken by Ferdinand III. in 1233, but was soon afterwards abandoned, and did not finally fall under the arms of Castile until May 23, 1499, when it surrendered to Ferdinand and Isabella after a siege.

LOKEREN, a town of Belgium, in the provinces of East Flanders and district of Termonde, on the Durme (a small but navigable stream by which it communicates with the Scheldt), and 11 miles from Ghent on the railway to Antwerp, which is there joined by the lines to Termonde and Alost, and to Zelzate. It is a busy manufacturing place, with cotton factories, ropewalks, and bleach-works, &c. The church of St Lawrence (17th century) has a fine pulpit, representing Jesus in the midst of the doctors. The population of the commune has increased from 11,960 in 1808 to 17,400 in 1876.

LOKMAN, a name famous in Arabian tradition. The Arabs distinguish two persons of this name. The older Lokman was an 'Adite, and is said to have built the famous dyke of Mu'rib. He not only escaped the destruction sent on his nation for their refusal to hear the prophet Hâd, but received the gift of a life as long as that of seven vultures, each of which is said to have lived eighty years. The other Lokman, called "Lokman the Sage," is mentioned in the Koran (xxx. 11). He is said to have been a Nubian slave, son of 'Ankâ, and to have lived in the time of David in the region of Elak and Midian (Masrûdy, l. 110), but the commentators on the Koran (Abu Sa'îd, ii. 336) make him son of Bâ'ura, the son of Job's sister or daughter. This form of the legend, and many of the stories told of him (D'Herbelot, s.v., but not those given by Nawawy, p. 526), show Jewish influence on the legend, and Derenbourg (*Fables de Lokman le sage*, 1850) has pointed out that Bâ'ura seems to be identical with Boor, and that Lokman corresponds to Balaam, the roots of both names meaning "to swallow," so that the one may be viewed as a translation of the other. In favour of this identification Derenbourg advances several important and probably conclusive arguments from Jewish tradition; but in view of the divergent accounts given of Lokman it may be questioned whether Jewish influence created or only modified the Arabian tradition. The grave of Lokman was shown on the east coast of the Lake of Tiberias, but also in Yemen and elsewhere (Yâkût, iii. 512; D'Herbelot, s.v.).

The name of Lokman is associated with numerous old verses, proverbs, and anecdotes of which Freytag, *Arabum Proverbia*, gives many examples. The fables which pass under his name, and were first printed by Erpenius (Leyden, 1616), are not mentioned by any Arabic writer. They appear to be of Christiana origin, and are mainly derived, though not closely copied, from those of Synopsus and Aesop. They existed in the 13th century (Derenbourg, *ut supra*). The editions are numerous, the book having been much used as an elementary Arabic reading-book. Those of Rodiger (2d ed. 1838, with glossary) and Derenbourg (1850) claim special mention.

LOLLARDS, THOMAS, were the English followers of John Wicliffe, and were the adherents of a religious movement which was widespread in the end of the 14th and begin-

ning of the 15th centuries, and which to some extent maintained itself on to the Reformation. The name is of uncertain origin: it has been traced to a certain Walter Lollard, but he was probably a mythical personage, some derive it from *lollum*, tares, quoting Chaucer (*C. T.*, Shipman's Prologue)—

"This Lollere here wol prechen us somwhat . . .
He wolde seuen some difficulte
Or sprengen oxide in ours clene corn."

but the most generally received explanation derives the words from *lollen* or *lullen*, to sing softly. The word is much older than its English use; there were Lollards in the Netherlands as early as the beginning of the 14th century, who were akin to the Fratricelli, Baghards, and other sectaries of the recussant Franciscan type. The earliest official use of the name in England occurs in 1387 in a mandate of the bishop of Worcester against five "poor preachers," *nomine seu ritu Lollardorum confederatos*. It is probable that the name was given to the followers of Wicliffe because they resembled those offshoots from the great Franciscan movement which had disowned the pope's authority and separated themselves from the medieval church. The 14th century, so full of varied religious life, made it manifest that the two different ideas of a life of separation from the world which in earlier times had lived on side by side within the medieval church were irreconcilable. The church chose to abide by the idea of Hildebrand and to reject that of Francis of Assisi, and the revolt of Ockham and the Franciscans, of the Baghards and other spiritual fraternities, of Wicliffe and the Lollards, were all protests against that decision. Hildebrand's object was to make church government or polity in all respects distinct from civil government—no civil ruler to touch churchman or church possession for trial or punishment, taxation or confiscation, and, in the hands of his successors who followed out his principles, the church became transformed into an empire in rivalry with the kingdoms, and of somewhat the same kind, only that its territories were scattered over the face of Europe in diocesan domains, convent lands, or priests' glebes, its taxes were the tithes, its nobles the prelates. Francis of Assisi had another ideal. Christians, he thought, could separate themselves from the world, in imitation of Christ, by giving up property, and home, and country, and going about doing good and living on the alms of the people. For a time these two ways of separation from the world lived on side by side in the church, but they were really irreconcilable; Hildebrand's church required power to enforce her claims, and money, land, position, were all sources of power. Church rulers favoured the friars when they found means of evading their vows of absolute poverty, and gradually there came to be facing each other in the 14th century a great political Christendom, whose rulers were statesmen, with aims and policy of a worldly ambitious type, and a religious Christendom, full of the ideas of separation from the world by self-sacrifice and of participation in the benefits of Christ's work by an ascetic imitation, which separated itself from political Christianity and called it anti-Christ. Wicliffe's whole life was spent in the struggle, and he bequeathed his work to his followers the Lollards. The main practical thought with Wicliffe was that the church, if true to her divine mission, must aid men to live that life of evangelical poverty by which they could be separate from the world and imitate Christ, and if the church ceased to be true to her mission she ceased to be a church. Wicliffe was a metaphysician and a theologian, and had to invent a metaphysical theory—the theory of *Dominium*—to enable him to transfer, in a way satisfactory to himself, the powers and privileges of the church to his company of poor Christians; but his

¹ Tabery, i. 240; Abul, H. A., 20; Dumfry, ii. 384. The tradition has various forms. Masûdy, iii. 366, 375, gives Lokman only the age of one vulture. Further details are given by Cassan de Perceval, *Revue*. The vultures of Lokman, especially the seventh, whose name was Lobad, are often referred to in Arabic poetry and proverbs.

followers, who were not troubled with need of theories, were content to allege that a church which held large landed possessions, collected tithes greedily, and took money from starving peasants for baptizing, burying, and praying, could not be the church of Christ and his apostles, who in poverty went about doing good.

Lollard was most flourishing and most dangerous to the ecclesiastical organization of England during the ten years after Wickliffe's death. It had spread so rapidly and grown so popular that a hostile chronicler could say that almost every second man was a Lollard. Wickliffe left three intimate disciples.—Nicolas Hereford, a doctor of theology of Oxford, who had helped his master to translate the Bible into English; John Ashton, also a fellow of an Oxford college; and John Purvey, Wickliffe's colleague at Lutterworth, and a co-translator of the Bible. With these were associated more or less intimately, in the first age of Lollardy, John Parker, the strange ascetic William Smith, the restless fanatic Swynderly, Richard Waytstract, and Crome, and there must have been a large number of preachers who itinerated through England preaching the doctrines of their master. Wickliffe had organized in Lutterworth an association for sending the gospel through all England, a company of poor preachers somewhat after the Wesleyan method of modern times. "To be poor without mendicancy, to unite the flexible unity, the swift obedience of an order, with free and constant mingling among the poor, such was the ideal of Wickliffe's 'poor priests'" (cf. Shirley, *Fuse. Zis*, p. 21), and, although proscribed, these "poor preachers," with portions of their master's translation of the Bible in their hand to guide them, preached all over England wherever they could be heard without detection. The Oxford university and many nobles supported them. Lord Montacute, Lord Salisbury, Sir Thomas Latimer of Braybrooke, and several others had chaplains who were Lollardist preachers; whilst many merchants and burgesses assisted the work with money. The organization must have been strong in numbers, but only the names of those have come down to us who were seized for heresy, and it is only from the indictments of their accusers that their opinions can be gathered. The preachers were picturesque figures in long russet dress down to the heels, who, staff in hand, preached in the mother tongue to the people in churches and graveyards, in squares, streets, and houses, in gardens and pleasure grounds, and then talked privately with those who had been impressed. The Lollard literature was very widely circulated,—books by Wickliffe and Hereford and tracts and broadsides,—in spite of many edicts proscribing it. In 1395 the Lollards grew so strong that they petitioned parliament through Sir Thomas Latimer and Sir R. Stury to reform the church on Lollardist methods. It is said that the Lollard Conclusions printed by Canon Shirley (p. 360) contain the substance of this petition. If so, parliament was told that temporal possessions ruin the church and drive out the Christian graces of faith, hope, and charity; that the priesthood of the church in communion with Rome was not the priesthood Christ gave to his apostles; that the monk's vow of celibacy had for its consequence unnatural lust, and should not be imposed; that transubstantiation was a feigned miracle, and led people to idolatry; that prayers made over wine, bread, water, oil, salt, wax, incense, altars of stone, church walls, vestments, mitres, crosses, staves, were magical and should not be allowed; that kings should possess the *jus episcopale*, and bring good government into the church; that no special prayers should be made for the dead; that auricular confession made to the clergy, and declared to be necessary for salvation, was the root of clerical arrogance and the cause of indulgences and other abuses in pardoning sin; that all wars

were against the principles of the New Testament, and were but murdering and plundering the poor to win glory for kings; that the vows of chastity laid upon nuns led to child murder; that many of the trades practised in the commonwealth, such as those of goldsmiths and armourers, were unnecessary and led to luxury and waste. These Conclusions really contain the sum of Wickliffe teaching, and, if we add that the principal duty of priests is to preach, and that the worship of images and going on pilgrimages are sinful, they include almost all the heresies charged in the indictments against individual Lollards down to the middle of the 16th century. The king, who had hitherto seemed anxious to repress the action of the clergy against the Lollards, spoke strongly against the petition and its promoters, and Lollardy never again had the power in England which it wielded up to this year.

If the formal statements of Lollard creed are to be got from these Conclusions, the popular view of their controversy with the church may be gathered from the ballads preserved in the collection of *Political Poems and Songs relating to English History*, published in 1859 by Mr Thomas Wright for the Master of the Rolls series, and in the *Piers Ploughman* poems. *Piers Ploughman's Creed* (see LARGELAND) was probably written about 1394, when Lollardy was at its greatest strength; the ploughman of the *Creed* is a man gifted with sense enough to see through the tricks of the friars, and with such religious knowledge as can be got from the creed, and from Wickliffe's version of the Gospels. The poet gives us a "portrait of the fat friar with his double chin shaking about as big as a goose's egg, and the ploughman with his hood full of holes, his mittens made of patches, and his poor wife going barefoot on the ice so that her blood followed" (*Early English Text Society*, vol. xxx, pref., p. 18); and one can easily see why farmers and peasants turned from the friars to the poor preachers. The *Ploughman's Complaint* tells the same tale. It paints popes, cardinals, prelates, rectors, monks, and friars, who call themselves followers of Peter and keepers of the gates of heaven and hell, and pale poverty-stricken people, cold and landless, who have to pay the fat clergy for spiritual assistance, and asks if these are Peter's priests after all. "I trowe Peter took no money, for no sinners that he sold. . . . Peter was never so great a fole, to leave his key with such a losell."

In 1399 the Lancastrian Henry IV. overthrew the Plantagenet Richard II., and one of the most active partisans of the new monarch was Arundel, archbishop of Canterbury and the most determined opponent of Lollardy. It has been alleged that Henry won his help by promising to do his utmost to suppress the followers of Wyclif, and this much is certain, that when the house of Lancaster was firmly established upon the throne the infamous *Act De comburendo hereticos* was passed in 1400, and church and state combined to crush the Lollards. John Purvey was seized, William Sautre (Chartrist) was tried, condemned, and burned. The Lollards, far from daunted, abated no effort to make good their ground, and united a struggle for social and political liberty to the hatred felt by the peasants towards the Romish clergy. Jak Upland (John Countryman) took the place of Piers Ploughman, and upbraided the clergy, and especially the friars, for their wealth and luxury. Wickliffe had published the rule of St Francis, and had pointed out in a commentary upon the rule how far friars had departed from the maxims of their founder, and had persecuted the *Spirituales* (the Fratricelli, Beghards, Lollards of the Netherlands) for keeping them to the letter (cf. Matthews, *English Works of Wyclif hitherto unprinted*, Early Eng. Text Soc., vol. lxxiv., 1880). Jak Upland put all this into rude nervous English verse:—

"Fier, what chaunte is this
To fain that whose lyveth after youi order
Livelh most perfectly
And next folloeth the state of the Apostles
In povertie and penance
And yet the wisest and greatest clerkes of youi
Wond or seil or procure to the court of Rome,
... and to be assailed of the vow of povertie."

The archbishop, having the power of the state behind him, attacked that stronghold of Lollardy the university of Oxford. In 1406 a document appeared bearing to be the testimony of the university in favour of Wickliffe; its genuineness was disputed at the time, and when quoted by Huss at the council of Constance it was repudiated by the English delegates. The archbishop treated Oxford as if it had issued the document, and procured the issue of severe regulations in order to purge the university of heresy. In 1408 Arundel in convocation proposed and carried the famous *Constitutions Thoma Arundel* intended to put down Wickliffe preachers and teaching. They provided amongst other things that no one was to be allowed to preach without a bishop's licence, that preachers preaching to the laity were not to rebuke the sins of the clergy, and that Lollard books and the translation of the Bible were to be searched for and destroyed. He next attempted to purge the nobility of Lollardy. The earlier leaders had died, but there was still one distinguished Lollard, Sir John Oldcastle, in right of his wife Lord Cobham, "the good Lord Cobham" of the common people, who had been won to pious living by the poor preachers, and who openly professed the common Lollard doctrines. His chaplain, one of the interesting preachers, was seized, then his books and papers were taken and burnt in the king's presence, and later he was indicted for heresy. It is said that at first he recanted, but the abjuration, said to be his, may not be authentic. In the end he was burnt for an obstinate heretic. These persecutions were not greatly protested against; the wars of Henry V with France had awakened the martial spirit of the nation, and little sympathy was felt for men who had declared that all war was but the murder and plundering of poor people for the sake of kings. Mocking ballads were composed upon the martyr Oldcastle, and this dislike to warfare was one of the chief accusations made against him (comp. Wright's *Poetical Poems*, vol. ii. p. 244). But Arundel could not prevent the writing and distribution of Lollard books and pamphlets. Two appeared just about the time of the martyrdom of Oldcastle—*The Ploughman's Prayer* and *the Lanthorne of Light*. *The Ploughman's Prayer* declared that true worship consists in three things—in loving God, and dreading God, and trusting in God above all other things; and it showed how Lollards, pressed by persecution, became further separated from the religious life of the church. "Men maketh now great stonon houses full of glasson windowis, and clepeth thilke thine houses and churches. And they setten in these houses mawmets of stoockes and stones, to fore them they knelen privelien and apert, and maken thier prayers; and all this they say is thy worship. . . . For Lorde our believ is that thine house is man's soul."

The council of Constance (1414-1418) put an end to the papal schism, and also showed its determination to put down heresy by burning John Huss. When news of this reached England the clergy were incited to still more vigorous proceedings against Lollard preachers and books. From this time Lollardy appears banished from the fields and streets, and takes refuge in houses and places of concealment. There was no more wayside preaching, but instead there were *conventicula occulta* in houses, in peasants' huts, in sawpits, and in field ditches, where the Bible was read and exhortations were given, and so

Lollardy continued. In 1428 Archbishop Chichele confessed that the Lollards seemed so numerous as evai, and that their literary and preaching work went on as vigorously as before. It was found out also that many of the poorer rectors and parish priests, and a great many chaplains and curates, were in secret association with the Lollards, so much so that in many places processions were never made and worship on saints' days was abandoned. For the Lollards if not stamped out were hardened by persecution, and became fanatical in the statement of their doctrines. Thomas Bagley was accused of declaring that if in the sacrament a priest made bread into God, he made a God that can be eaten by rats and mice, that the Pharisees of the day, the monks, and the nuns, and the friars, and all other privileged persons recognised by the church were limbs of Satan, and that anacular confession to the priest was the will not of God but of the devil. And others held that any priest who took salary was excommunicate; and that boys could bless the bread as well as priests.

From England Lollardy passed into Scotland. Oxford infected St Andrews, and we find traces of more than one vigorous search made for Lollards among the teaching staff of the Scottish university, while the Lollards of Kyle in Ayrshire were claimed by Knox as the forerunners of the Scotch Reformation.

The opinions of the later Lollards can best be gathered from the learned and unfortunate Peock, who wrote his elaborate *Thesaur* against the "Bible-men," as he calls them. He summed up their doctrines under eleven heads: they condemn the having of images in the churches, the going on pilgrimages to the memorial or "mynde places" of the saints, the holding of lauded possessions by the clergy, the various ranks of the hierarchy, the framing of ecclesiastical laws and ordinances by papal and episcopal authority, the institution of religious orders, the evilness of ecclesiastical decorations, the carcerousness of the mass and the sacraments, the taking of oaths, and the maintaining that war and capital punishment are lawful. When these points are compared with the Lollard Conclusions of 1385, it is plain that Lollardy had not greatly altered its opinions after fifty-five years of persecution. All the articles of Peock's list, save that as to the sacraments, are to be found in the Conclusions; and, although many writers have held that Wickliffe's own views differed greatly from that have been called the "exaggerations of the later and more violent Lollards," all these views may be traced back to Wickliffe himself. Peock's idea was that all the statements which he was prepared to impugn came from three false opinions or "movings," viz., that no governance or ordinance is to be esteemed a law of God which is not founded on Scripture, that every humble minded Christian man or woman is able without "faul and defaut" to find out the true sense of Scripture, and that having done so he ought to listen to no arguments to the contrary; in elsewhere add a fourth (vol. i. p. 102), that if a man be not only meek but also keep God's law he shall have a true understanding of Scripture, even though "no man ellis teche him save God." These statements, especially the last, show us the connexion between the Lollards and those mystics of the 14th century, such as Tauler and Ruysbroeck, who accepted the teachings of Nicholas of Basel, and formed themselves into the association of the Friends of God.

The question remains—What was the connexion between the Lollard movement and the Reformation in England? Many writers make Lollardy the forerunner of Reformation teaching; others, like Mr. Gauden, relying on the facts that the persecution of the Lollards did not rouse the English nation in the way that the martyrdom of Huss excited the Bohemians and that Lollardy had almost faded out of sight in the beginning of the 16th century, admit only a casual connexion between the two awakenings. The problem is scarcely one which can be settled by counting the numbers of Lollards convicted at different periods from the beginning to the end of the 16th century, or by pointing to the enthusiasm or indifference of the mass of the English nation to Lollard doctrines. The English Reformation down to the middle of Elizabeth's reign was much more a political than a religious movement with the great proportion of English people. Lollardy in its most essential and invariable characteristics had much more in common with medieval religious revivals than with Reformation piety, and Lollard preaching must have had much more resemblance to that of Ockham and his recessant Franciscans than that of Luther, Calvin, or Peter Martyr. But Lollardy did one thing for England which other medieval revivals did not do for the lands in which they

arose; it made the Bible familiar to the people in their mother tongue, and this must have been a positive preparation for the English Reformation of no ordinary power. May not the great peculiarity of the English Reformation on its religious side, the repeated attempts to give a good version of the Bible from the original tongue into English, by Tyndale, Coverdale, Taverner, Crammer, the Geneva refugees, and Parker, with the revisions and combinations of these various translations, on to our present authorized version, have come from the fact that Lollard Biblemen, as Peacock calls them, had made a good English Bible a necessity for an English reformation of religion?

LOMBARD, PETER (c. 1100–1160), bishop of Paris, better known as *Magister Sententiarum*, the son of obscure parents, was born about the beginning of the 12th century, at Novara (then reckoned as belonging to Lombardy). After receiving his education in jurisprudence and the liberal arts at Bologna, he removed to France, bearing a recommendation to Bernard of Clairvaux, who first placed him under Lotolf at Rheims, and afterwards sent him to Paris with letters to Ghilduin, the abbot of St Victor. His diligence and talents soon brought him into notice, and ultimately obtained for him a theological chair, which he held for a number of years; during this period he is said to have been the first to introduce theological degrees. On June 29, 1159, he succeeded his former pupil, Philip, brother of Louis VII., in the bishopric of Paris, but did not long survive the promotion; according to the most trustworthy of the meagre accounts we have of his life, he died on July 30 of the following year.

His famous theological handbook, *Sententiarum Libri Quatuor*, is, as the title implies, primarily a collection of "sententiae petrum,"¹ These are arranged (professedly on the basis of the aphorism of Augustine, Lombard's favourite authority, that "omnis doctrina vel rerum est vel signorum") into four books, of which the first treats of God, the second of the creature, the third of the incarnation, the work of redemption, and the virtues, and the fourth of the seven sacraments and eschatology. It soon attained immense popularity, ultimately becoming the text-book in almost every theological school, and giving rise to endless commentaries. A charge of heresy ("ultranianism") was indeed raised against Lombard for a particular view which he seemed not remotely to have indicated regarding Christ's human nature, but neither at the synod of Tours, where the question was first broached in 1168, nor at the subsequent Lateran synod in 1179, does a condemnation seem to have been obtained. In 1890 the theological professors of Paris agreed in the rejection of sixteen propositions taken from Lombard, but their decision was far from obtaining universal currency.

Besides the *Sententiae*, Lombard wrote numerous commentaries (e.g., on the Psalms, Canticles, Job, the Gospel Harmony, and the Pauline Epistles), sermons and letters, which still exist in MS. The *Glossae seu Commentaria in Prædicatorum Doctorum*, first published at Paris in 1838, and the *Collectanea in omnes D. Pauli Epistolae* (Paris, 1838) have been reprinted by Migne.

LOMBARDS. The history of the Lombards falls into three divisions:—(1) The period before the invasion in 568 A.D.; (2) the Lombard kingdom in Italy between 568 and 774; (3) the period of their incorporation with the Italian population, and the history of Lombardy and its cities as one of the great provinces of Italy—(a) from the restoration of the empire under Charles the Great (800) to the peace of Constance with Frederick Barbarossa (1183), and (b) from the declaration of independence to the time of the tyrannies and, afterwards, of the French, Spanish, and Austrian rule.

1. The name *Lombard* is the Italianized form of the national name of a Teutonic tribe, *Langobardi*, itself an Italian arrangement, based on a supposed etymology of the Teutonic *Langbard*, *Langobardi*, the form used when they are first named by Roman writers—Velleius and Tacitus. The etymology which made the name mean *Longbeard* is too obvious not to have suggested itself to Italians, and

perhaps to themselves (see Zeuss, 95, 109); it is accepted by their first native chronicler, Paul the Deacon, who wrote in the time of Charles the Great. But the name has also been derived from the region where they are first heard of. On the left bank of the Elbe, "where Bordo or Bord still signifies a fertile plain by the side of a river," a district near Magdeburg is still called the *Langbe Börde*; and lower down the Elbe, on the same side, about Lüneburg, the *Bardengau*, with its *Bardewik*, is still found; it is here that Velleius, who accompanied Theodoric in his campaign in this part of Germany, and who first mentions the name, places them. As late as the age of their Italian settlement the Lombards are called *Bardi* in poetical epiphs, though this may be for the convenience of metre.

Their own legends bring the tribe as worshippers of Odin from Scandinavia to the German shore of the Baltic, under the name of *Wendii*, a name which was given to them in a loose way as late as the 12th century (e.g., by Ordericus Vitalis; cf. Zeuss, 57). By the Roman and Greek writers of the first two centuries of our era they are spoken of as occupying, with more or less extension at different times, the region which is now Hanover and the Altmark of Prussia. To the Romans they appeared a remarkable tribe:—"gens etiam Germana feritate ferocior," says Velleius, who had fought against them under Theodoric; and Tacitus describes them as a race which, though few in numbers, more than held their own among numerous powerful neighbours by their daring and love of war. In the quarrels of the tribes they appear to have extended their borders; in Ptolemy's account of Germany, in the 2d century, they fill a large space among the races of the north-west and north. But from the 2d century the name disappears, till it is found again at the end of the 6th century as that of a half Christian tribe on the northern banks of the Danube. How they got there, and what relation these Langobards bore to those who lived in the 1st and 2d centuries on the west bank of the Elbe, we learn little from the vague stories preserved by their traditions; but they are described (B. G., ii. 14, 15) by Procopius, a contemporary, as subject to one of the most ferocious of the tribes on the Danube, the Heruli, also a Teutonic tribe, by whose oppression they were driven in despair to a resistance, which ended in the utter defeat and overthrow of their tyrants. We know nothing of the way in which Christianity was introduced among them, probably only among some of their noble families; but they were Arians like their neighbours and predecessors in Italy, the Goths, and like them they brought with them into Italy a hierarchy of bishops, priests, and deacons; but, while the Gothic Bible of Ulfilas is partially preserved, whatever religious literature the Langobards had in the shape of versions of the Scriptures or liturgical forms has utterly perished. They were among the Teutonic tribes which were generally on good terms with the empire, and were encouraged by it in their wars with their more barbarous neighbours. After defeating the Heruli and destroying their tribal organization, the Langobards attacked the Gepides with equal success, scattering the tribe or incorporating its survivors in their own host. They thus became the most formidable of the Teutonic tribes of the Danube. They had alliances with the distant Saxons, probably a kindred stock, and with the Huns and the Avars of the Danube. Their kings belonged to a royal line, and made marriages with the kings of the Franks and the other German nations. Their wars led them westwards, and for forty years they are said to have occupied Pannonia, the region between the Danube and the valleys of the Drave and Sava. Thus following the line of movement of the Goths, they resolved at last to strike for

¹ Except in the Anglo-Saxon *Treveler's Song*, of probably between 875–455; see Guest's *English Rhythms*, 2, 77, 88, 87.

the great prize which the Goths had won and lost. Through the eastern passes, and the border land of Friuli, they invaded Italy. It is said that they were invited by Narses, the conqueror of the Goths, in revenge for his ill treatment by the masters whom he had served.

2. In 568 Alboin, king of the Langobards, with the women and children of the tribe and all their possessions, with Saxon allies, with the subject tribe of the Gepidae, and a mixed host of other barbarians, descended into Italy by the great plain at the head of the Adriatic. There was little resistance to them. The war which had ended in the downfall of the Goths had exhausted Italy; it was followed by famine and pestilence; and the Government at Constantinople, away in the East, made but faint efforts to retain the province which Belisarius and Narses had recovered for it. Except in a few fortified places, such as Ticinum or Pavia, the Italians did not venture to encounter the new invaders, and, though Alboin was not without generosity, the Lombards, wherever resisted, justified the opinion of their ferocity by the savage cruelty of the invasion. In 572, according to the tragic tale of the Lombard chronicler, a tale which recalls the story of Candacius in Herodotus, Alboin, the fierce conqueror, fell a victim to the revenge of his wife Rosamond, the daughter of the king of the Gepidae, whose skull Alboin had turned into a drinking cup, out of which he forced Rosamond to drink; but the Langobards had already shown themselves in ravaging bands all over Italy, and in the north had begun to take possession. Military chiefs, whom, after the Latin writers, we call "dukes," corresponding to the German "Herzog," were placed, or placed themselves, first in the border cities, like Friuli and Trent, which commanded the north-eastern passes, and then in other principal places in Italy; and this arrangement became characteristic of the Lombard settlement. The principal seat of the settlement was the rich plain watered by the Po and its affluents, which was in future to receive its name from them; but their power extended across the Apennines into Liguria and Tuscan, and then southwards to the outlying dukedoms of Spoleto and Benevento. The invaders failed to secure any maritime ports such as Genoa, Pisa, Naples, Salerno, Ravenna, or any territory that was conveniently commanded from the sea. Pavia, or, as it was called, Ticinum, the one place which had obstinately resisted Alboin, became the seat of their kings, as it had been one of the seats of the Gothic kingdom.

After the short and cruel reign of Cleph, the successor of Alboin, the Lombards (as we may begin for convenience sake to call them) tried for ten years the experiment of a national confederacy of their dukes, without any king at their head. It was the rule of some thirty-five or thirty-six petty tyrants, under whose oppression and private wars even the invaders suffered, while the Italians were remorselessly trodden under foot. With anarchy among themselves and so precarious a hold on the country, hated by the Italian population and by their natural leaders the Catholic clergy, threatened also by an alliance of the Greek empire with their natural and persistent rivals the Franks beyond the Alps, they resolved to sacrifice their turbulent independence to the usual necessities of the Teutonic invaders which led to the election of a king. In 584 they chose Authari, the grandson of Alboin, and endowed the royal domain with a half of their possessions. From this time till the fall of the Lombard power before the arms of their rivals the Franks under Charles the Great, the kingly rule continued. Authari, "the Long-haired," with his Roman title of Flavius, marks the change from the warring of an invading host to the permanent representative of the unity and law of the nation, and the increased power of the crown, by the possession of a great

domain, to enforce its will. The independence of the dukes was surrendered to the king. The dukedoms in the neighbourhood of the seat of power were gradually absorbed, and their holders transformed into royal officers. Those of the northern marches, Trent and Friuli, with the important dukedom of Tivoli, retained longer the kind of independence which marchlands usually give where invasion is to be feared. The great dukedom of Benevento in the south, with its neighbour Spoleto, threatened at one time to be a separate principality, and even to the last resisted, with varying success, according to the personal characters of its dukes, the full claims of the royal authority at Pavia.

The kingdom of the Lombards lasted more than two hundred years, from Alboin (568) to the fall of Desiderius (774),—much longer than the preceding Teutonic kingdom of Theodoric and the Goths. But it differed from the other Teutonic conquests in Gaul, in Britain, in Spain. It was never complete in point of territory: there were always two, and almost to the last three, capitals—the Lombard one, Pavia, the Latin one, Rome, the Greek one, Ravenna; and the Lombards never could get access to the sea. And it never was complete over the subject race, it profoundly affected the Italians of the north, in its turn it was entirely transformed by contact with them, but the Lombards never overcame the natural repulsion of the two races, and never amalgamated with the Italians till their power as a ruling race was crushed by the victory given to the Roman element by the restored empire of the Franks. The Langobards, German in their faults and in their strength, but coarser, at least at first, than the Germans whom the Italians had known, the Goths of Theodoric and Totila, found themselves continually in the presence of a subject population very different from anything which the other Teutonic conquerors met with among the provincials.—Like them, exhausted, dispirited, unwelcome, but with the remains and memory of a great civilisation round them, intelligent, subtle, sensitive, feeling themselves infinitely superior in experience and knowledge to the rough barbarians whom they could not fight, and capable of hatred such as only cultivated races can nourish. The Lombards who came into Italy with the most cruel incidents of conquest, and who, when they had occupied the lands and cities of Upper Italy, still went on sending forth furious bands to plunder and destroy where they did not care to stay, never were able to overcome the mingled fear and scorn and loathing of the Italians. They adapted themselves very quickly indeed to many Italian fashions. Within thirty years of the invasion, Authari took the fancy of decking himself with the imperial title of Flavius, even while his hands were leading Italian captives in leash like dogs under the walls of Rome, and under the eyes of Pope Gregory; and it was retained by his successor. They soon became Catholics; and then in all the usages of religion, in church building, in founding monasteries, in their veneration for relics, they vied with Italians. Authari's queen, Theodelinda, solemnly placed the Lombard nation under the patronage of St John the Baptist, and at Monza she built in his honour the first Lombard church, and the royal palace near it. King Liutprand (713-744) bought the relics of St Augustine for a large sum to be placed in his church at Pavia. Their Teutonic speech disappeared; except in names and a few technical words all traces of it are lost. But to the last they had the unpardonable crime of being a ruling barbarian race or caste in Italy. To the end they are "nefastissimi," execrable, loathsome, filthy. So wrote Gregory the Great when they first appeared. So wrote Pope Stephen IV, at the end of their rule, when stirring up the kings of the Franks to destroy them. Authari's short reign (584-591) was one of renewed effort for con-

quest. It brought the Langobards face to face, not merely with the emperors at Constantinople, but with the first of the great statesmen popes, Gregory the Great (590-604). But Lombard conquest was bungling and wasteful. It was ever ready to lapse into mere plunder and warfare; and when they had spoiled a city they proceeded to tear down its walls and raze it to the ground. But Authari's chief connexion with the fortunes of his people was an important, though an accidental one. The Lombard chronicler tells us a romantic tale of the way in which Authari sought his bride from Garibald, duke of the Bavarians, how he went incognito in the embassy to judge of her attractions, and how she recognized her disguised suitor. The bride was the Christian Theodelinda, and she became to the Langobards what Bertha was to the Anglo-Saxons, and Clothilda to the Franks. She became the mediator between the Lombards and the Catholic Church. Authari, who had brought her to Italy, died shortly after his marriage. But Theodelinda had so won on the Lombard chiefs that they bid her as queen choose the one among them whom she would have for her husband and for king. She chose Agilulf, duke of Turin (592-615). He was not a true Langobard, but a Thuringian. It was the beginning of peace between the Lombards and the Catholic clergy. Agilulf could not abandon his traditional Arianism, and he was a very uneasy neighbour, not only to the Greek exarch, but to Rome itself. But he was favourably disposed both to peace and to the Catholic Church. Gregory interfered to prevent a national conspiracy against the Langobards, like that of St Brice's day in England against the Danes, or that later uprising against the French, the Sicilian Vespers. He was right both in point of humanity and of policy. The Arian and Catholic bishops went on for a time side by side; but the Lombard kings and clergy rapidly yielded to the religious influences around them, even while the national antipathies continued unabated and vehement. Gregory, who despaired of any serious effort on the part of the Greek emperors to expel the Lombards, endeavoured to promote peace between the Italians and Agilulf; and, in spite of the feeble hostility of the exarchs of Ravenna, the pope and the king of the Lombards became the two real powers in the north and centre of Italy. Agilulf was followed, after two unimportant reigns, by his son-in-law, the husband of Theodelinda's daughter, King Rothari (636-652), the Lombard legislator, still an Arian though he favoured the Catholics. He was the first of their kings who did for the Lombards what was done by all the Teutonic conquerors as soon as they felt themselves a nation on Roman soil; he collected their customs under the name of laws,—and he did this, not in their own Teutonic dialect, but in Latin. The use of Latin implies the use of Latin scribes or notaries, and implies that the laws were a notice to the Italians of the usages and rules of their conquerors, which, so far as they applied, were to be not merely the personal law of the Lombards, but the law of the land, and binding on Lombards and Romans alike. But such rude legislation could not provide for all questions arising even in the shattered and decayed state of Roman civilization. It is probable that among themselves the Italians kept to their old usages and legal precedents where they were not overridden by the conquerors' law, and by degrees a good many of the Roman civil arrangements made their way into the Lombard code, while all ecclesiastical ones, and they were a large class, were untouched by it.

The precise nature of the relations, legal and political, of the Lombards, as a conquering race, or a military caste, to the Italians is still a subject of controversy, owing to the prevailing mixture of clearness and obscurity in the documents of the time. There must have been, of course, much change of property; but appearances are conflicting as to the terms on which land generally was held by

the old possessors or the new comers, and as to the relative legal position of the two. Savigny held that, making allowance for the anomalies and usurpation of conquest, the Roman population held the bulk of the land as they had held it before, and were governed by an uninterrupted and acknowledged exercise of Roman law in their old municipal organization. Later inquirers, Leo, Troya, and more recently Hugel, have found that the supposition does not tally with a whole series of facts, which point to a Lombard territorial law ignoring completely any parallel Roman and personal law, to a great restriction of full civil rights among the Romans, analogous to the condition of the rayah under the Turks, and to a reduction of the Roman occupiers to a class of half-free "aldii," holding immovable tenancies under lords of superior race and privileges, and subject to the sacrifice either of the third part of their holdings or the third part of the produce. Probably something like this, with exceptions and anomalies, represents the state of things, at least at first, but it must be remembered that regular and consistent arrangements were very unlikely to have been thought of early in such a conquest as that of the Lombards, that the Romans suffered probably rather from the insolence of barbarians than from the rules of a constitutional settlement, and that a conquered race always and naturally exaggerates its own humiliations and grievances, and in this case has the chief telling of the story. It might also be expected that the tribal customs of Teutonic conquerors would be more modified in Italy than elsewhere, by the deeply-rooted traditions and customs of the old Roman rule. The Lombards were rough and harsh, and the Italians never ceased to hate them; but we know by experience how two portions of a population, possessed of equal civil rights can hate one another, where they differ in blood and history. The Roman losses, both of property and rights, were likely to be great at first, how far they continued permanent during the two centuries of the Lombard kingdom, or how far the legal distinctions between Rome and Lombard gradually passed into desuetude, is a further question. The legislation of the Lombard kings, in form a territorial and not a personal law, shows no signs of a disposition either to depress or to favour the Romans, but only the purpose to maintain, in a rough fashion, strict order and discipline impartially among all their subjects.

From Rothari (ob. 652) to Liutprand (712-744) the Lombard kings, succeeding one another in the irregular fashion of the time, sometimes by descent, sometimes by election, sometimes by conspiracy and violence, strove fitfully to enlarge their boundaries, and contended with the aristocracy of dukes inherent in the original organization of the nation, an element which, though much weakened, always embarrassed the power of the crown, and checked the unity of the nation. Their old enemies the Franks on the west, and the Slavs or Huns, ever ready to break in on the north-east, and sometimes called in by mutinous and traitorous dukes of Friuli and Trent, were constant and serious dangers. By the popes, who represented Italian interests, they were always looked upon with dislike and jealousy, even when they had become zealous Catholics, the founders of churches and monasteries; with the Greek empire there was chronic war. From time to time they made raids into the unsubdued parts of Italy, and added a city or two to their dominions. But there was no sustained effort for the complete subjugation of Italy till Liutprand, the most powerful of the line. He tried it, and failed. He broke up the independence of the great southern duchies, Benevento and Spoleto. For a time, in the heat of the dispute about images, he won the pope to his side against the Greeks. For a time, but only for a time, he deprived the Greeks of Ravenna. Aistulf, his successor, carried on the same policy. He even threatened Rome itself, and claimed a capitation tax. But the popes, thoroughly irritated and alarmed, and hopeless of aid from the East, turned to the family which was rising into power among the Franks of the West, the mayors of the palace of Austrasia. Pope Gregory III. applied in vain to Charles Martel. But with his successors Pippin and Charles the popes were more successful. In return for the transfer by the pope of the Frank crown from the decayed line of Clovis to his own, Pippin crossed the Alps, defeated Aistulf, and gave to the pope the lands which Aistulf had torn from the empire, Ravenna and the Pentapolis (754-756). But the angry quarrels still went on between the popes and

the Lombards. The Lombards were still to the Italians a "foul and horrid" race. At length, invited by Pope Adrian I, Pippin's son Charles once more descended into Italy. As the Lombard kingdom began, so it ended, with a siege of Pavia. Desiderius, the last king, became Charles's prisoner (774), and the Lombard power perished. Charles, with the title of king of the Franks and Lombards, became master of Italy, and in 800 the pope, who had crowned Pippin king of the Franks, claimed to bestow the Roman empire, and crowned his greater son emperor of the Romans (800).

3 To Italy the overthrow of the Lombard kings was the loss of its last chance of independence and unity. To the Lombards the conquest was the destruction of their legal and social supremacy. Henceforth they were equally with the Italians the subjects of the French king. Charles, the Carolingian king, expressly recognised the Roman law, and allowed all who would be counted Romans to "profess" it. Latin influences were not strong enough to extinguish the Lombard name and destroy altogether the recollections and habits of the Lombard rule. Lombard law was still recognized, and survived in the schools of Pavia. Lombardy remained the name of the finest province of Italy, and indeed for a time was the name for Italy itself. But what was specially Lombard could not stand in the long run against the Italian atmosphere which surrounded it, with its countless and subtle forces, social, political, and religious. Generation after generation passed more and more into real Italians. Antipathies, indeed, survived, and even in the 16th century called each other Roman or Langobard as terms of reproach. But the altered name of Lombard also denoted henceforth some of the proudest of Italians; and, though the Lombard speech had utterly perished, their most common names still kept up the remembrance that their fathers had come from beyond the Alps.

But the establishment of the Frank kingdom, and still more the re-establishment of the Christian empire as the source of law and jurisdiction in Christendom, had momentous influence on the history of the Italianised Lombards. The empire was the counterweight to the local tyrannies into which the local authorities established by the empire itself, the feudal powers, judicial and military, necessary for the purposes of government, invariably tended to degenerate. When they became intolerable, from the empire were sought the exemptions, privileges, immunities from that local authority, which, autocratic and anarchical as they were in theory, yet in fact were the foundations of all the liberties of the Middle Ages in the Swiss cantons, in the free towns of Germany and the Low Countries, in the Lombard cities of Italy. Italy was and ever has been a land of cities, and, ever since the downfall of Rome and the decay of the municipal system, the bishops of the cities had really been at the head of the peaceful and industrial part of their population, and were a natural refuge for the oppressed, and sometimes for the mischievous and the evil doers, from the military and civil power of the duke or count or judge, too often a rule of cruelty or fraud. Under the Carolingian empire, a vast system grew up in the North Italian cities of episcopal "immunities," by which a city with its surrounding district was removed, more or less completely, from the jurisdiction of the ordinary authority, military or civil, and placed under that of the bishop. These "immunities" led to the temporal sovereignty of the bishops; under it the spirit of liberty grew more readily than under the military chief. Municipal organization, never quite forgotten, naturally revived under new forms, and with its "consuls" at the head of the citizens, with its "arts" and "crafts" and "guilds," grew up secure under the shadow of the

church. In due time the city populations, free from the feudal yoke, and safe within the walls which in many instances the bishops had built for them, became impatient also of the bishop's government. The cities which the bishops had made thus independent of the dukes and counts next sought to be free from the bishops; in due time they too gained their charters of privilege and liberty. Left to take care of themselves, islands in a sea of turbulence, they grew in the sense of self-reliance and independence; they grew also to be aggressive, quarrelsome, and ambitious. Thus, by the 11th century, the Lombard cities had become "communes," communalities, republics, managing their own affairs, and ready for attack or defence. Milan had recovered its greatness, ecclesiastically as well as politically, it scarcely bowed to Rome, and it aspired to the position of a sovereign city, mistress over its neighbours. At length, in the 12th century, the inevitable conflict came between the republicanism of the Lombard cities and the German feudalism which still claimed their allegiance in the name of the empire. Leagues and counter-leagues were formed; and a confederacy of cities, with Milan at its head, challenged the strength of Germany under one of its sternest emperors, Frederick Barbarossa. The struggle was terrible. At first Frederick was victorious; Milan, except its churches, was utterly destroyed; everything that marked municipal independence was abolished in the "rebel" cities; and they had to receive an imperial magistrate instead of their own (1158-62). But the Lombard league was again formed. Milan was rebuilt, with the help even of its jealous rivals, and at Legnano (1176) Frederick was utterly defeated. The Lombard cities had regained their independence; and at the peace of Constance (1183) Frederick found himself compelled to confirm it.

From the peace of Constance the history of the Lombards is merely part of the history of Italy. Their cities were the ordinary form of most Italian cities. They quarrelled and fought with one another. They took opposite sides in the great strife of the time between pope and emperor, and were Guelph and Ghibelline by old tradition, or as one or other faction prevailed in them. They swayed backwards and forwards between the power of the people and the power of the few, but democracy and oligarchy passed sooner or later into the hands of a master who wielded his lordship under various titles, and generally at last into the hands of a family. Then, in the larger political struggles and changes of Europe, they were incorporated into a kingdom, or principality, or duchy, carved out to suit the interest of a foreigner, or to make a heritage for the nephew of a pope. But in two ways especially the energetic race which grew out of the fusion of Langobards and Italians between the 9th and the 12th centuries has left the memory of itself. In England, at least, the enterprising traders and bankers who found their way to the West, from the 13th to the 16th centuries, though they certainly did not all come from Lombardy, bore the name of Lombards. In the next place, the Lombards, or the Italian builders whom they employed or followed, the "masters of Cosmo," of whom so much is said in the early Lombard laws, introduced a manner of building, stately, solemn, and elastic, to which their name has been attached, and which gives a character of its own to some of the most interesting churches in Italy. (R. W. C.)

LOMBOK (called *Tanah Sasek* by the natives, and *Salaparan* or *Salaparang* by the Balinese, Lombok being properly the name only of a village on the north-east side), an island of the East Indian Archipelago, belonging to the Lesser Sunda group, and separated from Bali by the Strait of Lombok, from Sumbawa by the Strait of Alas. It stretches from about 116° 44' to 118° 40' E. long, and from 8° 12' to 9° 1' S. lat., and its area is estimated at 2080 square miles. Rising out of the sea with bold and often precipitous coasts, Lombok is mountainous towards the south, and in the north-east contains one of the principal volcanic summits of the whole archipelago—Rindjani or Peak of Lombok, 8688 feet according to Hornbough's measurement, 13,379 according to Melville de Carnbee, and 11,834 according to Smits. There is no active crater in

the island, but in 1815 it suffered severely from the eruption of Tombora on the neighbouring island of Sumbawa. Of the numerous streams by which it is watered none are navigable except by small boats; among the mountain lakes Segara Anak, lying some 9000 feet above the sea, is noteworthy in point of size. The best harbour is Ampanan (8° 34' 15" S. lat., 116° 3' 40" E. long.) on the west coast, often visited by European and American vessels; that of Labuhan Tring farther south is also good, but less frequented. Forest-clad mountains and stretches of thorny jungle alternating with rich alluvial plains, cultivated like gardens under an ancient and elaborate system of irrigation, make the scenery of Lombok exceedingly attractive; and to the naturalist it is of particular interest as the frontier island of the Australian region, with its cockatoos and megapods or mound-builders, its peculiar bee-eaters and ground thrushes. Rice is the principal export; ponies, skins, ducks' eggs and other eggs, and edible nests, are also sent from the island. The rajah of Lombok (who has his capital at Mataram, a large village on the west coast, and his country seat at Gunung Sari) is tributary to the sultan of Bali and Lombok; he has possession of the whole island, which was formerly divided into the four states of Karang-Asam Lombok on the west side, Mataram in the north-west, Pagarawan in the south-west, and Pagutan in the east. Balinese supremacy dates from the conquest by Agong Dahuran in the beginning of the present century; the union under a single rajah dates from 1839. The population is variously estimated. The *Woordenboek van Ned. Ind.* (1869) gives about 405,000 souls; Dehm and Wagner conjecture 100,000 in 1880. The greater proportion are Sasaks, as the Mohammedanized native stock are called; but the dominant Balinese, who still retain their Buddhist creed, may amount to about a twentieth of the whole.

LOMONOSOFF, MIKHAIL VASILIEVICH (1711-1765), was born in the year 1711, in the village of Denisovka (which in later times has had its name changed in honour of the poet), situated on an island not far from Kholmogor, in the government of Archangel. His father, a fisherman, took the boy as soon as he was ten years of age to assist him in the labours of his calling, but his eagerness for knowledge was unbounded. The few books accessible to him he almost learned by heart; and, seeing that there was no chance of his stock of knowledge being enlarged under the arctic skies of his native place, he resolved to betake himself to Moscow in the best way he could. An opportunity occurred when he was seventeen years of age, and by the intervention of friends he obtained admission into the Zaikonospasski school. There his progress was very rapid, especially in Latin, and in 1734 he was sent from Moscow together with other promising students to St Petersburg. There again his proficiency, especially in physical science, was remarked by all, and he was one of the young Russians chosen to complete their education in foreign countries. He accordingly commenced the study of metallurgy at Marburg; but, not content with his work under the professors, he now began to write poetry, imitating German authors, among whom he is said to have especially admired Günther. His *Ode on the Taking of Khotin from the Turks* was composed in 1739, and attracted a great deal of attention at St Petersburg. During his residence in Germany Lomonosoff married a native of the country, and found it difficult to maintain his increasing family on the scanty allowance granted to him by the St Petersburg Academy, which, moreover, was

irregularly sent. His circumstances became embarrassed, and he resolved to leave the country secretly, and to return home. On his arrival in Russia, after an adventure with a Prussian recruiting officer which at one time threatened serious consequences, he rapidly rose to distinction, and was made professor of chemistry in the university of St Petersburg, he ultimately became rector, and in 1764 secretary of state. He died in 1765.

The most valuable of the works of Lomonosoff are those relating to physical science, and he wrote upon many branches of it. His everywhere shows himself a man of the most varied learning. He compiled a Russian grammar, which long enjoyed popularity, and did much to improve the rhythm of Russian verse. Many of his poems are good, but they do not constitute his chief claim to be remembered. The school upon which he formed himself as a poet was a bad one. We must remember that these were the days of falsely-conceived classicism, and the French taste upon which all the literature of Europe was moulded. His great merit is that he belongs to the glorious band of patriots, which includes such men among Slavs as Dostoi Orlovich, Baich, and Piusius Trubetzkoy, — men whose object was to elevate and give dignity to their country, — earnest toilers in the field of national education.

LOMZA, or LOMŻA, a government of Russian Poland, is bounded on the N. by Prussia and the Polish government of Suwalki, on the E. by the Russian government of Grodno, on the S. by the Polish governments of Siedlec and Warsaw, and on the W. by that of Plock. It covers an area of 4670 square miles, or $\frac{1}{2}$ per cent. of all Poland. It is mostly flat or undulating, with a few tracts in the north and south-west, where the deeply-cut valleys give a hilly aspect to the country. Extensive marshes overspread it, especially on the banks of the Nareff, and in the east there are also good forests. Lomza is traversed by the Nareff, which flows from east to south-west, joining the Bóg in the south-western corner of the government. The Bóg flows along the southern border, joining the Vistula 20 miles below its junction with the Nareff. The inhabitants numbered 501,385 in 1872, the Poles constituting 76 per cent. of the population (or 35 per cent. when the Poles who are mixed with Lithuanians are included), the Jews 14½ per cent., and the Germans 2 per cent. Of this population 402,148 belonged in 1870 to the Catholic Church, 10,354 to the Protestant, and 1817 to the Greek and United Churches. In 1878 394,570 were peasants, while only 76,950 belonged to the citizen class, and 11,470 to the nobility (*szlachta*). In 1877 45 per cent. of the total area, or 1,366,000 acres, were under crops. Stock raising is carried on to some extent (197,900 cattle, 283,700 sheep, and 68,705 horses). The wood trade is an important branch of industry, but manufactures are very imperfectly developed, the total production in 1873 having been only some £110,000, or 1·5 per cent. of the total for Poland. Lomza produces some wooden wares, spirits, tobacco, and sugar. There is only one railway (between Grodno and Warsaw); the Bóg is navigable, but only wood is floated down the Nareff. The province is divided into eight districts, of which the chief towns are Lomza (13,860), Pultusk (7950), and Ostrolenka (6900) on the Nareff, Masowicz (2750), Ostrow (6300), Maków (6600), Kolno (4800), and Szczeczyn (4750). Tykocin (6400) and Nasielsk (6250), although not district towns, have lately acquired some importance.

LOMZA, capital of the above province, on the Nareff, 80 miles north-east from Warsaw, and 30 miles north from the Chizheff station of the railway between Warsaw and Grodno, had a population in 1872 of 13,860.

Lomza is an old town, one of its churches having been erected before the year 1000. In the 16th century it was carried on a bridge with Lithuania and Prussia. It was well fortified and had two citadels, but nevertheless had often to suffer from the invasions of Germans and Tartars, and in the 17th century it was twice plundered by the Cossacks of the Ukraine. In 1796 it fell under the dominion of Prussia, and after the peace of Tilsit it came under Russian rule.

LONDON, the metropolis of England, and the chief town of the British empire, is situated on both banks of the river Thames, about 60 miles from its mouth, St Paul's Cathedral being in $51^{\circ} 30' 45''$ N. lat and $0^{\circ} 8' 48''$ W. long. This old City of London is wholly included in the county of Middlesex, but the town beyond the City limits extends into portions of three other counties—namely, Surrey and Kent on the south, and Essex on the east. The area and population of the various governmental divisions of London are given below (pp 821, 822).

Geology

STR.—A great part of London is built on sands and gravels belonging to the Drift period, marking the ancient bed of a much larger river than the present Thames. This formation, resting immediately on the London Clay, extends along both banks of the present river, with an average breadth of about 2 miles; but in some parts there is immediately adjoining the banks a considerable breadth of alluvial deposits, or occasionally of artificially constructed embankments. On the north bank the alluvial soil comprehends the greater part of Westminster, on the south bank it stretches east from Lambeth Bridge, gradually widening to a breadth of about half a mile, and from Southwark to Deptford occupying a still wider area. The sands and gravels again occur at Greenwich Hospital, but are succeeded by the Greenwich and Woolwich marshes. The Isle of Dogs opposite Greenwich is constructed wholly of artificial embankments, and at one time the area it now occupies formed part of the mouth of the Lea, along whose banks the alluvial formation runs northwards between Bow and Stratford to Stoke Newington, widening to a considerable area at the marshes of West Ham and Plaistow. At Farnham, Battersea Park, Chapside, Victoria Park, and to the south of Stoke Newington, there are considerable areas occupied by brick earth. The London Clay crops to the surface throughout the whole of north-west London, with the exception of a small portion to the south of Regent's Park, which is encroached upon by the sands and gravels, and the summits of Hampstead and Highgate, which are occupied by the silicious sands of the Bagshot series. In west London the Clay extends south to Kensington Gardens, and in north London it occupies part of Islington and the district north of Highbury and Stoke Newington. South of the Thames it encroaches regularly on Wandsworth, Clapham, Camberwell, and Deptford, and comprehends nearly all the district round Sydenham. The Lower Tertiaries are represented by the Thanet sands at Greenwich and in the neighbourhood of Deptford, by the Woolwich and Reading beds, which occur at Camberwell, Dulwich, and Lewisham, and by the Blackheath beds, which are best seen at Blackheath. Chalk, the basement rock of the London basin, and the source of the water supply for the deep wells, only crops to the surface in the neighbourhood of Greenwich.

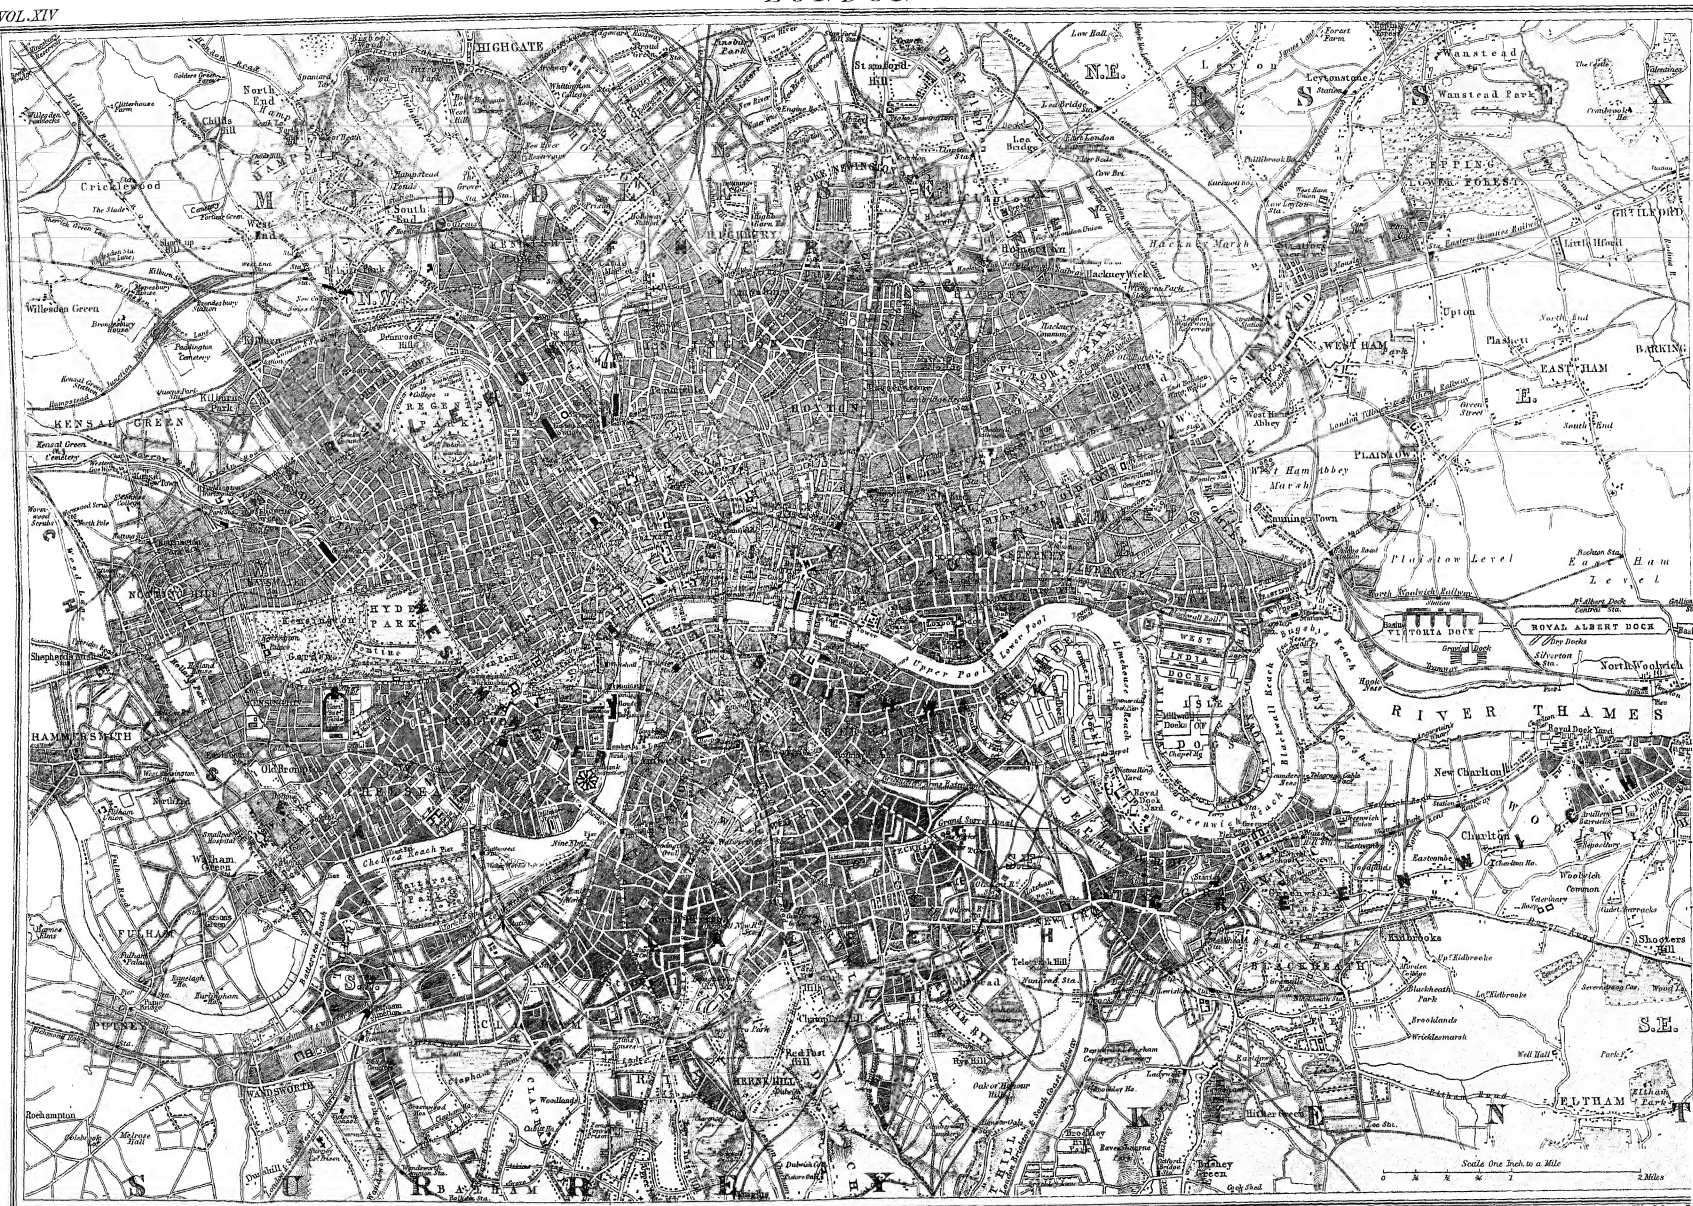

Surface

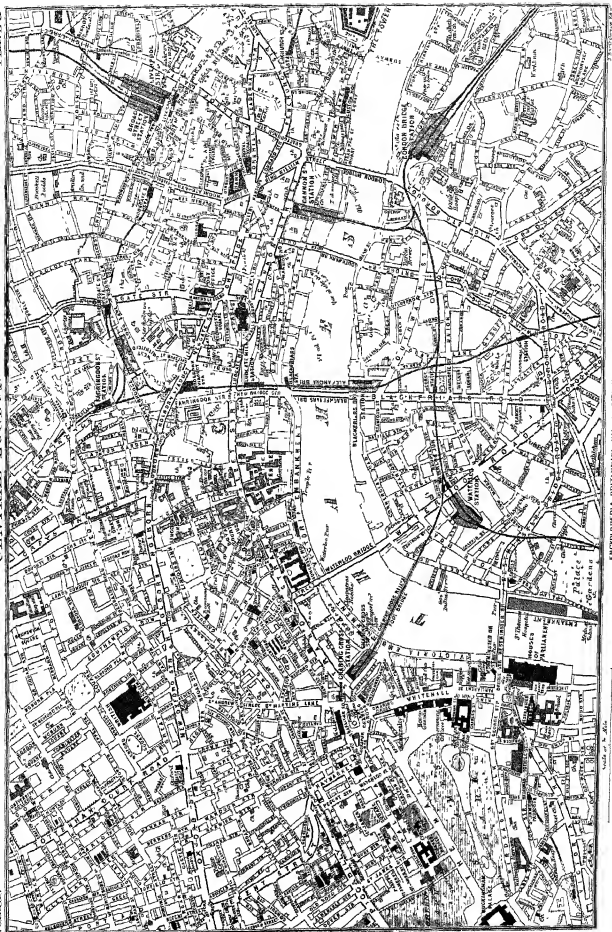

The original surface of the soil of London has been much altered in the course of generations, the depth of made earth being often very great. At one period the Thames flowed straight from Lambeth to Limehouse, and the greater part of the district now stretching south and east of the river to the range of heights in the neighbourhood of Sydenham and Greenwich was occupied by marshes or shallow lagoons. North of the Thames the greater part of London is built on several ranges of small eminences lying between the river and the northern heights of Hampstead (430 feet), Highgate, and Hornsey. The original city clustered round the eminence now crowned by St Paul's, and formerly intersected by the ravine of the Walbrook.

To the north and east it was bounded by an extensive fen, from which Finsbury takes its name. To the west was the Fleet river, which flowed from Hampstead in a southeasterly direction to King's Cross, and then more southerly to Clerkenwell, where on account of the steepness of its banks it received the name of Holbourne or Hollowburn. It was navigable to King's Cross, and for a long period formed a convenient and well-protected harbour for the city. A more extended elevation, included in the district now occupied by the Inns of Court, Bloomsbury, and Soho, was bounded on the west by the Tyburn, which rose near the Swiss Cottage and, after an easterly course till reaching the present Regent's Park, flowed southwards nearly in the line of Marylebone Lane and Bond Street. Tyburn Hill was bounded on the west by the Westbourne; and to the south and west an extensive range of low ground, now included in Westminster, Pimlico, Chelsea, and Kensington, was in early times for the most part covered by water. Westwards the low ground is bounded by Notting Hill, whence an elevated region lying between the smaller eminences and the "northern heights," and including Primrose Hill, runs in a north-westerly direction to Camden Town, Islington, and Highbury. The hilly regions in the neighbourhood of Kensington and Notting Hill formed part of an extensive forest, and St John's Wood was originally a dense thicket.

GOVERNMENT AND ADMINISTRATION.—At first the *Admna* municipal constitution of London was loose and disjointed *history.*

in its form, resembling that of the shire rather than the town, but even from the time of Henry I. the independence of its jurisdiction was complete, and the citizens, besides the right of inheritance and tenure not then possessed by the rest of England, enjoyed exemption from the Danegeld and from similar obligations. By the 13th century the later form of the municipality was already shaped in its main features, although at this stage residence in the borough and not membership in a trade guild was the basis of citizenship. This in some respects premature development of municipal functions has always given to London a peculiar and unique position in respect of municipal government. Its charters, which in early times served as the model for charters to new incorporations, have defied the attacks of reform. The system of government was more heterogeneous and complicated than that of other English towns. London is practically a borough by prescription, and its special rights and privileges have made those who possess them distrustful of change. The mere extent of the new city surrounding the old, and the rapidity of its growth, have also tended to postpone the attempt to grapple with the problem of its government. Until 1855, when the Metropolitan Board of Works was formed, the whole administration of the metropolis was of a mediæval character. The City was governed by old charters, confirmed but not interpreted by a special Act of William and Mary, and the various parishes of the rest of the metropolis had each its own peculiar system of administration, regulated by local Acts which differed widely in different localities. No direct change of vital importance was made in the constitution and functions of the City corporation by the Metropolitan Local Management Act of 1855, but the very existence of the Metropolitan Board implied a certain limitation of its authority, and the additional functions conferred by successive Acts on the Metropolitan Board have in some degree circumscribed its influence. As modified by the Act of 1855, the government of London within what is known as the metropolitan area consists of the City Corporation, the Metropolitan Board of Works, and thirty-eight

vestries and district boards; while various authorities, to be afterwards mentioned, exercise jurisdiction in special matters over the whole area of the metropolis or in separate localities.

The City of London, which is a county in itself, and with which the borough of Southwark is assimilated, is governed by a lord mayor, twenty-six aldermen, and two hundred and six common councilmen, forming a Court of Common Council. This court has a certain independent power to enact regulations for the government of the City, is entrusted with the management of the finances and the estates of the corporation, elects most of the officials, and controls the police. The City elects a sheriff of Middlesex as well as a sheriff of London; and the lord mayor is elected by the trade guilds in common hall from among the aldermen who have served as sheriffs. He is lord lieutenant within the City, the dispenser of its hospitality, the chairman of the courts of the corporation, and holds certain other offices, the dignity of which is now almost entirely nominal. The aldermen, who hold office for life, are chosen by the several wards, each ward electing one. Since 1867 the power of election has been enjoyed by all possessing the household and lodger franchise. The Court of Aldermen has the power of appointment to certain offices, exercises judicial functions in regard to licensing and in disputes connected with the ward elections, has some power of disposal over the City cash, and possesses magisterial control over the City, each alderman being a judge and magistrate for the whole City, and by virtue of his office exercising the functions of a justice of the peace. The common councillors were chosen originally in the reign of Edward I. as assistants to the aldermen, and in 1384 were constituted a standing committee to regulate the affairs of the City, each ward choosing four, six, or eight, according to its size. A gradual increase in their number took place until 1840, when it was fixed at two hundred and six.

From the time of Richard II. the election was vested in freemen householders, but it is now regulated by the Act of 1867. The Court of Common Hall, formerly the popular assembly or ancient *folk-mote*, is now composed of the lord mayor, four aldermen, and the liverymen of the city guilds, and nominates yearly two aldermen, who must previously have been sheriffs, for the Court of Aldermen to select one for the office of lord mayor. The sheriffs are themselves chosen by the Court of Common Hall, which also appoints the chamberlain, the bridge masters, and the city auditors.

The fragmentary and indirect participation in the government of London at present exercised by the livery companies represents the remnants of an influence which was paramount from the time of Edward III., when enactments were passed which made admission to the freedom of the city dependent on membership in a trade or mystery. Originally established to afford mutual aid to members of their "craft," the guilds of London gradually assumed a certain control over their trade or manufacture, and by the payment of large sums of money obtained various monopolies, with the power to make by-laws for the regulation of their craft. From gifts for charitable purposes, and from entrance money and fines, many of the guilds, on account of the rise in the value of property, have amassed enormous wealth. Within the limits of the City alone the gross annual rental of the land possessed by them is over £500,000, and it is believed that the land they possess outside its limits is of equal value. At one time their number was over one hundred, but they now number seventy-six, and some represent trades which are extinct. Twelve so-called "great companies" claim precedence over the others, but of these some are not so wealthy as a few of the less highly privileged. The "livery" or dress of the companies, first formally adopted

in the reign of Edward III., was ultimately worn only by a higher grade of the members called liverymen. The extension of London beyond the City limits and changes in trade maxims and in social life have now left them little more than the shadow of their former authority over trade and manufacture, but a few, such as the fishmongers, the stationers, the goldsmiths, and the apothecaries, still discharge certain functions in the regulation of their several crafts. Besides administering their charities, many of the companies contribute largely to benevolent objects of pressing need, and some take an interest in promoting technical instruction, and in various matters relating to their special trade or manufacture; but the business of most of them is now chiefly of a ceremonial kind. The halls of the companies number thirty-five, and many of them are of interest either from their architectural merits, their antiquarian associations, or the portraits or other objects they contain. Their annual assessed value is over £60,000. The hereditary connexion of the companies with the corporation, their large ownership of property in the City, and their control over so many charities still enable them to exercise a very great influence in municipal affairs.

The following list (Table I.) gives details regarding the twelve great companies, and six other companies which may be ranked next to them in importance—

Name	Date	Situation of Hall	Parishes of Freedom	Livery Admission
			£ s. d.	£ s. d.
<i>Great Companies</i>				
Barbers	1295	Chancery	4 11 0	38 10 0
Drapers	1304	Throgmorton Street	106 0 0	26 6 0
Goldsmiths	1307	Upper Thames Street	112 15 0	51 15 0
Goldsmiths	1327	Foster Lane	1 10 0	58 7 0
Skinner	1327	Dowgate Hill	94 0 0	80 8 0
Mercantile Tailors	1408	Thames Embankment	54 0 0	20 0 0
Haberdashers	1449	Gratham Street	110 1 8	45 0 0
Salters	1480	St. Martin's Lane	110 1 8	45 0 0
Ironmongers	1484	Foreburch Street	110 1 8	45 0 0
Vintners	1488	Upper Thames Street	110 1 8	45 0 0
Clockmakers	1580	Minding Lane	110 1 8	45 0 0
<i>Other Companies</i>				
Apothecaries	1615	Water Lane	105 0 0	28 0 0
Armourers	1659	Colman Street	118 25 0	28 9 8
Barbers	1659	Monkwell Street	60 0 0	40 8 8
Goldsmiths	1659	Gratham Street	60 0 0	40 8 8
Salters	1659	Chancery	60 0 0	40 8 8
Stationers	1659	Lodgate Hall	38 0 0	70 0 0

The corporation of the City of London still retains certain exceptional prerogatives. The lord mayor's court still exercises civil jurisdiction, the two courts of the sheriffs' compter survive in the City of London court, and the lord mayor exercises the functions of judge in the central criminal court, which superseded the court of oyer and terminer in 1834, and extends beyond the radius of the Metropolitan area. The corporation possesses the sole right to establish markets within 7 miles of the City; it enjoys a messuage of grain, partially commuted in 1872 to a fixed duty chargeable by weight, and applied to the preservation of Epping Forest and other open spaces; and it leases coal and wine duties, continued by various Acts, for defrayment of the cost of public improvements. Most of the work of the corporation is performed by committees; and "commissioners of sewers," under Act of Parliament, have charge of the cleaning, lighting, and paving of the streets.

A large portion of the City income is derived from rents, which City have increased from £24,458 in 1692 to £16,192 in 1785, £45,969 accounts in 1826, and £17,781 in 1851. In 1692 the City markets were farmed for £3100, the profits being about £2600; in 1785 their revenue was £15,681, and the profit £2621; in 1826 these were respectively £33,668 and £69,271; and in 1851 they were £159,816 and £20,611. The total revenue of the City in 1692 was £11,955, in 1785 £59,866, and in 1851 £294,688, not including the public and trust accounts, which are regulated by various Acts of Parliament. They include the Bridge-House estate account, the sewers rate, the Metropolitan Board of Works sewers rate, the police rate, the ward rate, and the duties on coal, wine, and grain. The total charge of the government establishment in 1692 was £2847, and in 1851 it was £51,855, not including £7556 spent in pensions of

Special
prerogatives
of the City
corporation

officials. In 1692 the lord mayor received an annual sum of £100 for his care of the market, and an annual fee of £80 out of the chamber. He has now an annual salary of £10,000, and in addition to this his personal expenses in 1881 amounted to £4438. The salaries of the recorder, the chamberlain, the common sergeant, the town-clerk, and some other officers have risen in a somewhat arbitrary proportion. The City in 1692 spent nothing on special acts of hospitality or on the promotion of literature, science, or art, while its contribution to the poor rates was only £66. It now spends several thousands annually on the reception of eminent persons, while to the London almonshouses it in 1881 contributed £1894, to general charitable purposes £3179, for education £3894, for technical instruction £2900, for the Guildhall library and museum £5898, and for music £3037. The debt of the corporation, which is solely connected with the construction of improvements and public markets, was on December 31, 1881, £5,456,150, the money spent for these purposes since 1769 being nearly £10,000,000. The rateable value of the City and liberties has since 1801 increased sevenfold, having risen from £507,572 to £3,585,484.

Corporation
buildings.

The Guildhall, rebuilt by Dance in 1789, contains the greater part of the walls of the old building of 1411, which was damaged by the fire of 1666, and also the crypt divided into three aisles by clustered columns of marble supporting a groined roof richly adorned with carvings. The principal front was restored in 1867 in the Gothic style. In addition to the great hall used for state banquets and receptions, the building contains the common council chamber, the aldermen's room, and several courts of justice. Adjoining the Guildhall is the free library of the corporation, and a museum of antiquities relating to the City. The Mansion House at the east end of the Poultry, erected in 1740 from the designs of Dance, is the official residence of the lord mayor. In addition to the justice room and various reception rooms, it contains the Egyptian hall, in which certain special banquets of the lord mayor are held.

Metropolitan
Board.

By the Metropolitan Local Management Act of 1855, the metropolis was divided into thirty-nine vestries or district boards, which elect the forty-five members who form the Metropolitan Board of Works, the city of London electing three members, each of the six great parishes of Islington, Marylebone, St Pancras, Lambeth, St George's (Hanover Square), and Shoreditch two members, and the other districts one each or one in combination. The board was originally established for the formation and maintenance of main sewers, but later Acts have made it the administrative authority of the metropolis in a great variety of other matters, including the construction of main thoroughfares, the carrying out of great metropolitan improvements, the formation of new streets, the construction and maintenance of parks, the preservation of commons and open spaces, the maintenance of the fire brigade, and the administration of certain enactments specially applicable to the metropolitan area. The total sum raised by the board for application to its various purposes since 1856 to 31st December 1881 was £28,689,749, and its net liability on the 31st December 1881 was £13,437,940. The capital required for the execution of great works is raised by the issue of stock bearing interest at the rate of 3½ and 3 per cent, which has the same facilities of transfer as the Government stocks, and is redeemable in sixty years from creation. The rate per pound levied by the board has varied very greatly, being 2.09d. in 1856, and as high as 6.99d. in 1867, while for 1883 it is estimated at 8.2d. The total net charge in 1880 was £662,213, and for 1882 it is estimated at £718,822. The rateable annual value of property in the metropolis has risen from £11,283,663 in 1856 to £27,386,086 in 1882.

Vestries.

The vestries and district boards are entrusted with the management of local sewers, the lighting, paving, and cleaning of their own thoroughfares, and the removal of nuisances. For paving, except in the old main thoroughfares, they have power to charge adjoining properties, and in several districts a small income is obtained from

realized property. The total amount of money advanced to them on loan by the Board of Works up to 31st November 1881 was £3,631,769, of which £3,297,480 was redeemable by 1929, and £334,338 by 1941.

The School Board of London has in regard to education other a rating and legislative authority over a district corresponding with that of the Metropolitan Board of Works. The metropolitan police force outside the City limits and within a radius of 12 miles of Charing Cross is under the control of the Home Secretary. The Tower of London is governed by the constable of the Tower, assisted by fifty magistrates, and the borough of Westminster is still under the nominal care of the dean and burgesses. The Metropolitan Asylums Board, the Burial Board, the Thames Conservancy Board, and the Lea Conservancy Board constitute the principal other direct governing authorities having relation to London, but the water and gas companies enjoy monopolies which imply a certain degree of irresponsible authority, and a right of taxation not sufficiently defined and limited. Within an area less than the district of the Board of Works there are ten parliamentary boroughs, which return in all twenty-two members, the City returning four members, and Southwark (from 1296), Westminster (1847), Marylebone (1832), Finsbury (1832), Tower Hamlets (1832), Greenwich (1832, extended in 1869), Lambeth (1832), Hackney, (1868), and Chelsea (1868) two each. London University (1868) returns one member.

GROWTH AND POPULATION.—For some centuries after Growth.

the Conquest there are almost no data for an estimate of the extent and population of London, but a great impulse was given to its increase by the settlement of Normans and the opening up of intercourse with the Continent. The statement of Fitzstephen that it furnished, in the reign of Stephen, 60,000 men-at-arms and 20,000 knights cannot be accepted as applying only to the City. Peter of Blois, under Henry II., only estimated its numbers at 40,000, although he may possibly have referred only to adults (*Opera*, ed. Giles, vol. ii. p. 85). In any case, previous to the great plague of 1349 it must have numbered at least 90,000, for in that year, according to Stow, as many as 50,000 persons were buried in the cemetery of Spitalrook, specially consecrated for the purpose. There were severe ravages from the same cause in 1361 and 1389, and the calculation of Chalmers (*Comparative Estimate of Great Britain*, 1802), founded on the Subsidy Rolls of 1377, shows a population of only 34,971; but the emperor Manuel II., who visited it in 1400, states that it was to be preferred to every city of the West for population, opulence, and luxury (Macpherson, *Annals of Commerce*, vol. i. p. 611). Notwithstanding the regulations of Elizabeth for checking its growth, London had by the end of the century advanced considerably beyond its old boundaries. Giovanni Botero, writing about 1590, classes it with Naples, Lisbon, Prague, and Ghent as possessing about 160,000 inhabitants more or less, while Paris was said to possess over 400,000 inhabitants. The "Bills of Mortality," which were begun in 1592, were in 1604 extended to St Bartholomew the Great, Bridewell Precinct, and Trinity in the Minories, which were partly within the City liberties, and to St Clements Danes, St Giles-in-the-Fields, St James (Clerkenwell), St Catherine (Tower), St Leonard (Shoreditch), St Mary in Whitechapel, St Martin-in-the-Fields, and St Mary Magdalen (Bermondsey). St Mary at the Savoy was added in 1606, and Westminster in 1626. The parishes of Hackney, Islington, Lambeth, Newington, Rotherhithe, and Stepney, which were included in 1636, were, according to Grant (*Observations on the Bills of Mortality*, 1676), still country villages in 1672, and indeed occupied an isolated position up to the middle of the 18th century. The result of the census of the

city taken in 1631 is given by Graunt as 130,178, but the sum of his details is 130,268. By 1661 he reckoned it to have increased to 179,000. He also concluded that the population within the limits of the "Bills of Mortality" was 460,000, and that from the beginning of the century it had increased from 2 to 5. The population of London and its suburbs, excluding Westminster and the distant parishes, he placed at 384,000, or about a fourth less than Paris. Notwithstanding the plague of 1665 and the fire of 1666, London towards the close of the 17th century increased with great rapidity. Evelyn, writing in 1684, states that it had nearly doubled within his own recollection. Sir William Petty, in his *Essay on Political Arithmetic*, estimated the population in 1683, including that of Westminster and Southwark, at 696,000, but Gregory King, in his *Observations on the State of England*, first published by Chalmers, allowing $\frac{1}{3}$ persons to every house, makes it in 1694, within the limits of the "Bills of Mortality," only 530,000. From about this period London superseded Paris as the largest city in Europe. During the first half of the 18th century its progress was fluctuating, but on the peace of 1763 a great impulse was given to its prosperity, and after 1780 a rapid rate of progress commenced, which still shows no signs of diminution. Until 1756 there was sufficient space for the Mayfair east of Hyde Park, but by the end of the century the aristocracy had nearly all migrated west from Covent Garden and Soho. Islington was still almost disjoined from the metropolis, but the great eastern suburbs had become so consolidated as almost to absorb even Hoxton, Bethnal Green, and Stepney. The first census of 1801 included St Pancras, Marylebone, Paddington, Kensington, and Chelsea, but Chelsea was still a solitary suburban retreat, Kensington was little more than "the old court suburb," Paddington and Westbourne were rural hamlets, and Marylebone and St Pancras had less than one-fourth of their present population. The populous city surrounding Regent's Park had scarcely any existence before 1820, but by 1830 it as well as Somers Town had become absorbed in the metropolis, especially by additions in the neighbourhood of St Pancras church and London university. Eastwards the most rapid extension had been in the direction of Greenwich, which was now united with Lambeth by a continuous line of houses. Belgravia in the south-west, and Tyburnia to the north of Hyde Park are chiefly the product of the next twenty years. Since that period the suburban districts have in all directions become almost consolidated, and beyond the present limits

of the registrar-general fringes of houses, extending in some instances outside even the 12 miles circuit from Charing Cross, connect the metropolis with populous towns which a few years ago were solitary hamlets. Within the last twenty years the rate of increase of the outer ring of this greater London has been 126·8 per cent, while that of London proper has been only 36·0, its outer ring showing an increase of 63·8 per cent, but its central area a decrease of 13·2,—the decrease in the City being 54·3, in the Strand 30·5, St Giles 16·3, Holborn 9·5, Westminster 11·9, St George's (Hanover Square) and Marylebone 4·1, and in the eastern central districts of Whitechapel, St George-in-the-East, and Shore-ditch 9·3, 3·8, and 2·2 respectively. In these latter districts the decrease has been occasioned chiefly by improvements, but in the central business districts it is almost entirely the result of the substitution of business premises for dwelling-houses. The day census of the City taken in 1866 shows that the number of persons employed daily within its limits was 170,133, and that of 1881 gives a day population of 261,061, while the night population in 1871 was 74,897 and in 1881 only 50,526. The rapidity of the growth of London is largely due to the peculiar development of its trade and commerce, and is also closely connected with the interest excited by politics and the meetings of parliament. The bonds of connexion between London and England thus pulsate daily with a manifold vitality. London is the emporium of England, the centre of its great monetary transactions, the home of its science, literature, and art, and the yearly resort of its aristocratic and landed proprietor classes. Since the beginning of the century its rate of increase has exceeded that of England generally.

The proportion of inhabitants born outside its limits amounts to Nation-one-third of its entire population. The number of the natives of European states is in excess of those born in Scotland, and that of the natives of Ireland is about double, while the natives of the counties of England and Wales amount to more than a million. Inhabited by descent may be estimated at about 360,000 persons, Scots 120,000, foreigners 200,000, viz. Austrians, Germans, and Americans together 48,000, Europeans 166,000 (Germans 60,000, French 80,000, Dutch 16,000, Poles 12,000, Italians 7,500, Swiss 5,000). The number of Jews is about 40,000. The special foreign district of London is that of Soho; another foreign district lies in the neighbourhood of Ratcliff Highway, near St George Street. The lower-class Jews inhabit the neighbourhood of Houndsditch and Aldgate. The Italian street musicians and vendors of ice form a small colony near Hatton Garden.

Table II shows the percentage of the population of London to Tables of the rest of England, the numbers before 1801 being only approximate; Table III. the areas, houses, and population of London in round.

various governmental divisions; and Table IV, the population of the several registration districts at different periods from 1801.

Streets.

STREETS, BRIDGES, &c.—By the non-adoption of Wren's plans the opportunity afforded through the great fire was for ever lost of constructing a model capital, and within the City limits the streets are still in many cases confused and intricate. The total absence of plan in the construction of the nucleus of London has doubtless tended to aggravate the confusion outside the old boundaries. The growth of the immense new outer city was, moreover, for centuries totally unregulated by the control of any central authority. The principal lines of streets formed along the old public highways are insufficient as main lines of communication for the increased population, and the absence of direct connexion between important points causes traffic to be enormously impeded. The longest line of street communication in London is that which is formed by the junction of the lines of the Edgeware and Uxbridge Roads at the Marble Arch, whence it extends eastward by Oxford Street, Holborn, Newgate Street, Chapside and other important City streets, Whitechapel Road, and Mile End Road to Bow. At Chapside a branch from it runs westward by Fleet Street, the Strand, Haymarket, Piccadilly, and Knightsbridge to Kensington. Much of the effect of the fine architecture of the City streets is totally lost from promiscuous crowding, and the main connecting streets between the City and the West End display, at certain parts, much meanness and incongruity. Regent Street, the most fashionable thoroughfare of London, possesses ample width, and the splendour of its shops to some extent atones for the plain monotony of its regular architecture. In Oxford Street, which ranks next to it in importance, many buildings of a more ornamental character have lately been erected. Piccadilly, the eastern half of which is occupied chiefly by shops, and the western by dwelling houses and clubs, is a medley of every species of architecture, but is to some extent effective from the variety of its contrasts, and its outlook to the Green Park.

Travellers Square, with its fountain, its Nelson column, its statues, and its wide expanse, has an airy and pleasant effect, but the huge erections which surround it are a very miscellaneous group, and few of them are worthy of the site. The clubs and hotels in Pall Mall and its neighbourhood represent every variety of Grecian and Italian architecture. The private houses in the more fashionable regions are not remarkable for external beauty, but in summer time flowers and foliage give the West End squares and terraces a bright and pleasant aspect. A special characteristic of London is the enormous space covered by the suburban cottages and villas of the middle classes. Close to the most fashionable regions there are many mean back streets tenanted by workmen, but the principal territories of the working classes are comprehended in the dense and dreary districts east and south-east of the City. The improvements lately carried out in the City and other central districts, and the substitution of business premises for dwelling houses, have compelled large numbers of these classes to live at a long distance from their work, and also caused undue crowding in the less remote regions. The running of workmen's trains from the suburbs and the efforts of various private building associations and of the Metropolitan Board, guided by the Artisan and Labourers' Dwellings Improvement Act, have only partially mitigated these evils.

Since 1785 the greater part of London within the City Street limits has been rebuilt, and its streets have been much improved. The principal improvements being the reconstruction of the lines from London Bridge to Finsbury Pavement, and from Blackfriars Bridge to Farringdon Road, both intersecting the City from north to south; the rebuilding of Bartholomew Lane, Lothbury, Threadneedle Street, and Cannon Street from King William Street to St Paul's; and the construction, in conjunction with the Metropolitan Board, of the Holborn Viaduct and of Queen Victoria Street from Blackfriars Bridge to the Mansion House. The Metropolitan Board now exercises a certain

control over the formation of new streets, but its powers are hampered by previous circumstances and by various restrictions. The principal new thoroughfares opened up by the board, besides Queen Victoria Street and the Holborn Viaduct, are Garsick Street, Covent Garden (1861), Southwark Street (1864), Northumberland Avenue (1876), and Theobald's Road and Clerkenwell Road, begun in 1873 to connect Oxford Street and Old Street. They have also effected extensive improvements in the neighbourhood of Whitechapel, Shoreditch, Park Lane, and Kensington. The more important schemes in contemplation are a new street from Tottenham Court Road to Charing Cross, another from Oxford Street to Piccadilly Circus, the widening of Coventry Street, of Gray's Inn Road, and of Tooley Street, and alterations of a less extensive character at Kentish Town, Hackney, and Camberwell. A scheme has been put forth by Government to relieve the pressure at Hyde Park Corner. Altogether up to 31st December 1881 the board have expended in street improvements £6,531,856, of which probably one-third will be defrayed by sales of property. In addition to this over £4,000,000 have been spent on the Thames Embankment and Queen Victoria Street, and the board have contributed about £296,077 to defray local improvements by district boards and vestries, as well as £1,360,500 for artisans' dwellings.

Thames
Embank-
ment.

The Thames Embankment, with its marine wall of large granite blocks facing the river, supports on the north side a spacious thoroughfare which forms one of the finest promenades in London. The total cost of the various portions of the embankment was over £3,000,000, the greater part of which is being defrayed by the coal and wine duties levied by the City corporation. By the construction (1864-70) of that portion known as the Victoria Embankment, stretching from Blackfriars Bridge to Westminster, about 37 acres of land have been reclaimed, of which 19 are occupied by carriage and footways, 7½ have been conveyed to adjoining proprietors, and about 8 have been formed into ornamental grounds. The Albert Embankment (1865-68), stretching on the south side of the river from Westminster Bridge to Vauxhall Bridge, includes about 9 acres, which are now chiefly occupied by St Thomas's Hospital. The Chelsea Embankment (1871-74), which is the extension of one previously constructed between Vauxhall Bridge and Chelsea Hospital, involved the reclamation of about 9½ acres of ground, now occupied partly by a roadway 70 feet wide, and partly by a flower garden.

Bridges.

There are twelve bridges, other than railway bridges, over the Thames within the metropolitan area, the most easterly being London Bridge and the most westerly Hammersmith Bridge. Three of these, London Bridge, Southwark Bridge, and Blackfriars Bridge, are within the City area. New London Bridge, a noble structure by Rennie, was opened in 1831, having cost £1,458,511. As populous and busy commercial districts extend for several miles to the east of it on both sides of the Thames, it is not only totally inadequate for the requirements of traffic, but is also removed beyond many convenient lines of communication. On this latter account the proposal to widen it—in itself a very unsatisfactory plan—has met with almost no support; but a bill promoted by the Metropolitan Board for erecting a high level bridge at the Tower failed also to commend itself to a committee of the House of Commons. Until 1769, when the Blackfriars Bridge was erected, London Bridge stood alone. Old Blackfriars Bridge was replaced in 1899 by the present one of five iron arches resting on granite, erected from the designs of Page at a cost of £230,000. Southwark Bridge, designed by Rennie, 1815-19, consists of three iron arches of great elegance resting on stone piers, and cost £280,000. Partly from

the unsuitability of its approaches, it has not proved of very much service.

The number of passengers and vehicles passing over the London and Blackfriars Bridges in a single day of 1833 is given in the July number of the *Monthly Review* for that year, and in 1881 similar information was obtained, in regard to the three bridges, for the traffic in the direction of the City. Multiplying these figures by two, we find that the foot passengers crossing London Bridge in 1833 numbered 48,440, while in 1881 they were 157,585, and that the number of vehicles had increased from 6183 to 21,466; the over Blackfriars Bridge the passengers had increased from 6108 to 87,134, and the vehicles from 4047 to 14,534, while 80,090 passengers and 3560 vehicles passed over Southwark Bridge, the increase in the number of passengers over the three bridges being thus 194,401, and of vehicles 26,831. At the earlier date Southwark Bridge was practically unused, but in 1856 the toll was abolished, and the bridge purchased by the corporation for £214,363. The Metropolitan Toll Bridges Act of 1877 required the Metropolitan Board to extinguish the tolls on all the Thames bridges and the bridge over Deptford Creek, and thereafter to repair and maintain them, the county authorities of Middlesex and Surrey paying each £1200 a year towards their maintenance. The bridges treated by the Act were the Charing Cross foot-bridge, for which £93,640 was paid to the South-Eastern Railway, Waterloo Bridge (1811-17), designed by Rennie in a style similar to London Bridge, constructed at a cost of £1,000,000, and purchased for £175,000; Lambeth Bridge (1802), built of iron at a cost of £240,000, and purchased for £26,049; Vauxhall Bridge (1811-16), similar in form to Southwark Bridge, erected for over £200,000, and purchased for £255,320; Chelsea Suspension Bridge (1858), designed by Page, erected by the Government for £23,000, purchased for £75,000; the Albert Suspension Bridge (1878) and Battersea Bridge, an old wooden structure, both purchased for £300,000; Wandsworth Bridge for £59,761; Putney Bridge (1728), a picturesque old timber structure, for £53,000, and Hammersmith Bridge for £112,550. Battersea and Putney bridges are about to be re-erected, and Deptford Creek Bridge is to be widened and improved at a cost of £180,000. The total amount of money spent by the board in connexion with bridges up to 18th December 1881 was £1,479,697. The amount to be paid by the board for their maintenance in 1882 is estimated at £26,502. The river is crossed by many railway bridges, and the Thames tunnel, begun in 1825 and completed in 1841 at a cost of £468,000, for the purpose of traffic, was purchased in 1856 by the Great Eastern Company, and is now used as a railway tunnel. A subway under the Thames from Tower Hill to Tooley Street was constructed in 1869 at a cost of £16,000. The communication in the neighbourhood of the river is greatly facilitated by the frequent passenger steamers.

The cleaning, watering, and paving of the streets are more satisfactory than might be expected from the fact that each district townships depends solely on its own local authority. Several Acts for paving of streets have been passed in the 14th century, and in the 15th century for the streets outside the City. In 1614 the custom began to pave the margins of the streets before their doors, but the middle of the streets were laid with large pebbles very unevenly. In 1661 the money obtained from hackney coach licences, 25 for each annually, was applied to keeping them in repair. The use of squared granite blocks, with raised footways, was introduced by Acts of Parliament for Westminster in 1761, and for London generally in 1766. Within the last twenty years asphalt and wooden pavement have been largely substituted for granite in the principal thoroughfares.

Hackney coaches are first mentioned in 1625, when they were conveyed at night, and numbered altogether only 30. In 1659 their number was limited to 300, in 1682 to 400, in 1694 to 700, in 1715 to 800, in 1771 to 1000, and in 1799 to 1200. In 1833 the restriction of their number was abolished. The number of cab drivers in 1671 was 10,048, and of cabs 7813, of which 616 were hackneys and 4528 four-wheelers, in 1831 the number of drivers was 12,930, and of cabs 9552, of which 6805 were hackneys and only 3547 four-wheelers. Omnibuses were first introduced in 1829. Many of the principal streets are too crowded for trams, but in South London trams are more used than omnibuses, and there are also several routes in the northern and eastern districts. The Metropolitan and Metropolitan District Railway lines, which run partly underground, and form almost a complete belt round the "inner circle" of London, with several branches interesting it, and others communicating with various suburban lines, have proved invaluable in relieving the throng of vehicles on the streets, and in affording rapid communication between important points; but the railway system in and around London has suffered greatly in directness from the absence of a complete plan embracing proper connecting links between the lines of the several districts, and the small number of passengers on the Metropolitan Railway is now about 60 millions. The Regent, Grand Junction, and several other canals, besides connecting London with the internal navigation of

England, supply a means of transport for heavy goods between various districts of the metropolis.

Postal districts.—London is divided into eight postal districts, viz., Eastern Central (E.C.), Western Central (W.C.), Northern (N.), North-Western (N.W.), Western (W.), South-Western (S.W.), South-Eastern (S.E.), and Eastern (E.). In the E.C. district there are twelve deliveries of letters daily, in the town portions of the other districts, which extend to about 5 miles from the General Post-Office, eleven deliveries, and in the suburban portions six deliveries.

OPEN SPACES.—London owes the possession of its finest parks rather to accident than to intention. Eastwards and northwards no effort was made to preserve any part of the "delightful plain of meadow land interspersed with flowing streams" mentioned by Fitzstephen, or of the "immense forest of densely wooded thickets," or of the "common fields" in the great fen, notwithstanding the riot of the citizens in the reign of Henry VIII. against the invasion of their rights by enclosure. Westward, however, the inroads of the builder were interrupted by the royal parks, which, lying adjacent to each other, cover an area of about 900 acres. St James's Park, 80 acres, transformed from a swamp into a deer park, bowling green, and tennis court by Henry VIII., extended and laid out as a pleasure ground by Charles II., and rearranged by Nash (1827-29), possesses beautiful combinations of water and foliage. Green Park, 70 acres, lying between St James's Park and Piccadilly, is unadorned except by rows of trees and by patterns of flowers bordering Piccadilly. Hyde Park, 350 acres, stretches westward from the district of Mayfair to Kensington Gardens. Originally forming part of the manor of Hyde, which was attached to Westminster Abbey, Hyde Park at the dissolution of the monasteries was taken possession of by Henry VIII. In 1652 the park, which then included a large portion of the ground now joined to Kensington Gardens and extended to 621 acres, was sold for £17,068, 6s. 8d., but in 1680 it was rebought by the Crown, having some time before this become the great " rendezvous of fashion and beauty." It possesses nine principal gateways, of which that at Hyde Park Corner on the south-east and the Marble Arch on the north-east present the most striking features. The former, designed by Decimus Burton and erected in 1828 at a cost of £17,000, consists of three imposing arches adorned with reliefs copied from the Elgin marbles. The Marble Arch, originally intended as a monument to Nelson, was first erected at a cost of £80,000 in front of Buckingham Palace, and was placed in its present position in 1861. With its fine expanse of grass, its bright flower beds and clumps of shrubbery, its noble old trees, its beautiful ornamental lake the Serpentine, its broad avenues crowded with equipages, its Rotten Row alive with equestrians, its walks lined with thousands of loungers of very various nationalities, professions, and grades of social position, Hyde Park in the height of the season presents a scene which in the brilliancy of its *tout ensemble* and its peculiarly mingled contrasts can probably be paralleled nowhere else. In the 17th and 18th centuries Hyde Park was a favourite meeting place for duellists, and in the present century has been frequently the scene of great political gatherings. To the west are Kensington Gardens, 360 acres, originally attached to Kensington Palace, and enlarged in the reign of George II. by the addition of nearly 300 acres taken from Hyde Park. They are more thickly planted than the "Park," and also contain an avenue of rare plants and shrubs, and several walks lined with flowering trees. Regent's Park in the north-west, 470 acres, occupying the site of Marylebone Park, which in the time of Elizabeth was used as a hunting ground, owes its preservation to the intention of George III. to erect within it a royal palace. It contains the gardens of the Zoological Society and of the Royal Botanic Society, as well as the grounds of a few private

villas. The northern half of the park is in summer devoted to cricket; in the south-east corner there is a flower garden of rather antique design; and in the south-west a portion bounded on the north by an artificial lake is let to private householders. To the north of Regent's Park there are other about 12 acres of open ground surrounding Primrose Hill, 230 feet, commanding an extensive view of London. Battersea Park, 180 acres, formed (1853-58) at a cost of £312,890, on the south side of the Thames, besides a fine promenade along the banks of the river, several walks and carriage drives bordered with parterres, and a wide expanse for cricket and other amusements, contains a subterranean garden, which during August and September possesses much of the witchery of an ideal fairy-land. East London, after the enclosure of Finsbury Fields, had no special recreation ground until the opening of Victoria Park, which was sanctioned by an Act of Parliament in 1842, and was in 1872 increased to about 300 acres. Finsbury Park, 115 acres, formed by the Metropolitan Board of Works from the grounds of Hornsey Wood House at a cost of £112,000; Southwark Park, Rotherhithe, 63 acres, formed at a cost of £111,000; West Ham Park in the extreme east, partly purchased by the City corporation, Greenwich Park (see GREENWICH); and the gardens on the Thames Embankment, with various squares and semi-private gardens, sum up the other ornamental open spaces of London.

The Metropolitan Board, under various Acts of Parlia- Public ment, have secured the exclusive right of the public in several commons and open spaces, which with the parks under their care comprise together an area of 1698 acres, giving with the royal parks and Battersea Park, Victoria Park, and West Ham Park a total of over 3000 acres, or about a twentieth-fifth part of the whole metropolitan area. The principal public commons are Hampstead Heath, a wildilly region now encroached on by buildings on all sides except the north and north-west, commanding fine views both of London and the country, and, with its clear bracing air and its unkempt and rugged beauty, breaking on the vision with all the effect of a sudden surprise, Bickhath Common, 267 acres, a bare sandy expanse to the south of Greenwich Park, containing a good golfing course, Clapham Common, 220 acres; Wormwood Scrubs, 194 acres; the Tooting Commons, 207 acres; and Plumstead Common, 110 acres. The total sum expended by the Board of Works in the purchase, preservation, and adornment of parks and open spaces up to 31st December 1881 was £436,760. All the parks and open spaces already mentioned are included in the Metropolitan Board district, but outside this area there is in the neighbourhood of London a large number of unencultivated spaces to which the public have various rights, some of them of an obscure and undefined character. A return made to the House of Commons in 1865 gives the area of public commons within radii of 25 miles and of 15 miles of the metropolis, the area of those within the smaller circuit being 13,301 acres. Of Epping Forest 5600 acres have been secured to the public by the corporation of the City, and in 1871 an Act was passed for the preservation of Putney Heath and Wimbledon Common, but Hounslow Heath, of old the favourite resort of highwaymen, and at one time over 4000 acres in extent, is now nearly all under cultivation. Richmond Park, the grounds of Hampton Court Palace, the gardens at Kew, the fine surroundings of the Crystal and Alexandra Palaces, the cricket grounds at the Oval and Lord's, may practically be also reckoned among the public parks of London. In addition to this the river Thames itself supplies facilities for recreation which are safe from the inroads of the builder; and all round the metropolis there are numerous footpaths through the open fields.

WATER SUPPLY.—For two centuries after the Conquest,

Water
supply

London obtained a sufficient supply of pure water partly from the rivers or streams which passed through it and partly from wells sunk into the sands above the chalk. Holywell, Clerk's Well (Clerkenwell), and St Clement's Well (near St Clement's Inn) are mentioned by Fitzstephen as those "of most note." In 1236 the magistrates purchased from Gilbert Sandford the liberty to convey the waters of the Tyburn from Faddington in leaden pipes to the city, and a great conduit of lead castled with stone was begun in West Cheap in 1285. Various other conduits were built in the 14th and 15th centuries, some for the water of the Thames, from which also the inhabitants were supplied by the city company of water bearers, who brought it in leathern panniers along on horses. In 1583 a great step in advance was taken by Peter Moris, a Dutchman, the real originator of the Thames water companies, who erected a "forrier" on an arch of London Bridge to convey the Thames water into the houses in the east end of the city as far as Gracechurch Street; in 1594 another was erected near Broken Wharf for West Cheap, Fleet Street, and the district round St Paul's, and in 1610 a third at Aldersgate without the gate. Moris, who obtained the lease of one arch of London Bridge for five hundred years at a rental of 10s. per annum, and two years later the use of another arch, erected for his purpose very ingenious machinery; and the works continued until 1701 in the possession of the family, who after amassing large wealth sold the lease to a company for £30,000. They ultimately occupied four arches, and continued till 1822, when the supply was purchased by the Southwark Company for £10,000. In 1806 an Act was passed for supplying the northern districts from springs near Ware in Hert. This enterprise was in 1609 undertaken by Hugh Myddelton, who, when his funds became exhausted in 1612, received the necessary money from James I. on condition of his sharing in the profits. With this assistance the reservoirs at Clerkenwell supplied by the New River were opened in 1613. In 1630 a scheme to bring water to London and Westminster from Hoddenden in Hert was promoted by aid of a lottery licensed by Charles I. on condition that the

promoters should pay £4000 per annum into the king's treasury. Styrpe, writing in 1720, mentions that "there is not a street in London but water runs through it in pipes conveyed underground, and from those pipes there is scarce a house whose rent is £15 or £20 per annum but hath the convenience of water brought into it," while "for the smaller tenements there is generally a cock or pump convenient to the inhabitants." In 1721 the Chelsea Water Company began to supply water from the Thames to Westminster and the parts adjacent, and in 1783 the supply of south London was supplemented by the erection of the Lambeth water-works opposite Charing Cross. The Vauxhall Company was established at Vauxhall Bridge in 1805, the West Middlesex near Hammer-smith in 1806, the East London on the River Lea at Bow in the same year, the Kent on the Ravensbourne at Deptford in 1810, the Grand Junction at the Grand Junction Canal in 1811, and the Southwark at London Bridge in 1822. For several years before the interference of parliament the companies had agreed to restrict themselves to separate localities. The Acts of 1847 required the companies to provide pure and wholesome water for the use of the inhabitants in the districts supplied by them, and also to provide water for general use. An Act passed in 1852 compelled the removal of the companies beyond the tidal limits of the Thames, contained regulations as to rates, enforced thorough filtration, and endeavoured to make provision for a constant supply. The rates, which differ in the various companies, were in some respects amended by the Act of 1871, but, as it fails to guard against claims for back dividends, no sufficient guarantee is provided against the raising of the rates. These are charged chiefly on the value of the houses, but the Acts do not distinguish with sufficient clearness between the gross annual value and the rental. A proposal in 1880 to purchase the rights of the companies, whose capital was then a little over £12,000,000, for £24,180,000, failed to commend itself to a committee of the House of Commons.

Their accounts being made up at different periods, it is impossible to give comparative returns for the companies, the following are the figures (Table V), as best they can be stated, for two years—

	Ordinary Capital	Piety and Loss Capital	Total Capital	Total Expenditure	Income	Working Expenses	Dividends
1871-2	£7,000,000	£2,000,000	£9,000,000	£10,107,710	£992,010	£250,950	£700,250
1880-1	8,000,000	3,448,961	11,448,961	11,612,669	1,502,784	619,500	921,985
Increase	1,000,000	928,961	2,448,961	9,474,879	510,774	368,550	152,229

Within ten years the increase of capital has thus been about 24 per cent., or 2½ per cent. per annum, the increase of the income 64 per cent., or 6½ per cent. per annum, and of the expenses 87 per cent., or 8½ per cent. per annum. Thus, while in 1871 there was a capital of 10 millions, gaining 6 per cent. profit, in 1881 there was a capital of 12½ millions producing 7½ per cent. Within the last two years the value of the property has been increasing at a more rapid rate, and probably at the rate of £1,250,000 per annum; but, as on account of the proposals to buy up the rights of the companies they have at present special reasons for curtailing expenses and delaying the carrying out of all but essential improvements, it is impossible to know how much of the increase is temporary and artificial.

According to Dr Frankland the water of the Thames and the Lea, notwithstanding the most efficient possible filtration, are, on account of sewage pollution, becoming less and less fit for domestic use, about one-half of the water at present supplied being already grossly polluted, and a very large proportion of the remainder occasionally polluted. He therefore recommends that the supply of water

for domestic use should be taken from the springs of the basin before they reach the river. At the present rate of the increase of London the supply required will, however, within forty years exceed that which may be obtainable in the whole Thames basin in times of summer drought, such as may occur in any year, and thus in a future not far distant a means of storage must be provided, or a new source of supply discovered, involving an outlay which would at least double the rates on the present rental. The Kent Company, which obtains its supply from the chalk wells, is the only one possessing wholly unpolluted sources, but the New River Company also obtains about one-tenth of its supply from springs, the remainder being obtained from the Lea. The East London Company obtains its supplies from the Lea and Thames, and the other companies from the Thames alone. The following table (VI.) gives certain particulars:—

Authorized Daily Supply from Thames.	Other Sources.	Average Supply from Thames.	Other Sources.	No. of Houses on Constant Supply.	Estimated Population Supplied.	Subsidiary Storage.		Filtered Storage.		Miles of Main in the Metropolis.	Miles of Main in the County of Chancery.
						Area.	Capacity.	Area.	Capacity.		
10,000,000	Not Estimated.	58,000,000	75,000,000	612,000	120,000	4,000,000	4,000,000	4,000,000	4,000,000	3,707	740

Oil
methods
of
lighting

LIGHTING.—From 1416 the citizens of London were under an obligation to hang out candles between certain hours on dark nights for the illumination of the streets; and in 1691 a special Act of Parliament was passed to enforce the custom. The corporation in 1684 granted a licence to Edward Heming, the inventor of oil lamps, for the sole supply of the public lights for twenty-one years, but the duty was then once more assigned to the individual citizens. A second agreement with contractors not proving satisfactory, the corporation in 1736 obtained from parliament permission to erect lights where they thought proper, and to levy a rate, which in that year yielded £15,000. Gas-lighting was in 1807 introduced in Pall Mall by the erection of a small apparatus to supply the lamps on the one side of the street, the other being still lighted with oil. In 1810 the Gas Light and Coke Company received a charter permitting it to supply gas to any persons within "the cities of London and Westminster, and the borough of Southwark," and as the result of their enterprise Westminster Bridge in 1818 was lighted with gas, and in 1814 the whole of the streets of St Margaret's parish. The City of London Gas Company was formed in 1817, and soon afterwards other seven companies. After several years' wasteful competition the companies came to an agreement in 1857 to restrict themselves to separate localities. This led to the Metropolitan Gas Act of 1860, the only effectual provisions of which were those in reference to the quality of the gas. The City of London Gas Act of 1868, limiting the price of gas within the City to 3s. 9d. per 1000 feet, except in certain cases, was the only other measure of a restrictive character passed before 1876, and previous to this the companies, by amalgamation, and through the favourable terms on which they were allowed to increase their capital and to raise new shares, had economically increased the value of their dividends. The Act of 1876, from the provisions of which the London Gas Company is exempt, adopted a sliding scale of dividends, one half of the profits, after a 10 per cent dividend had been paid, going to the shareholders, the other being applied to reduction in the price of the gas, it being also provided that the price should not be more than 3s. 9d., and that when additions were made to the capital the shares should be put up to auction. The experimental introduction of the electric light by the commissioners of sewers of the City, and by the Metropolitan Board (for the Thames Embankment and some of the bridges), has led the gas companies to provide better lights in some of the more important streets.

The following table (VII.) will show that the prosperity of the companies¹ has not been affected by the legislation of 1876, and as yet has not materially suffered from the threatened competition of electric lighting:—

	Total Gas Companies, Year ending December 31, 1880	Total, Year ending December 31, 1874.	Increase or Decrease— from 1874 to 1880.
Amount of capital authorized ..	12,000,719	10,469,900	+1,530,819
Paid up capital ..	10,786,761	8,887,280	+1,899,481
Capital remaining to be paid up ..	1,213,958	1,582,620	-368,662
Reserve fund ..	3,867,277	2,006,067	+1,861,210
Total capital remaining to be borrowed ..	1,701,806	229,484	+1,472,322
Amount of capital on which 10 per cent. is paid ..	1,007,720	1,266,800	-259,080
Total income ..	9,388,428	8,705,108	+683,320
Total expenditure ..	2,794,583	3,077,598	-283,015
Total gas sales ..	8,012,444	5,627,510	+2,384,934
Consumption for public lighting ..	327,571	298,397	+29,174
Coal carbonized ..	1,008,544	1,444,000	-435,456
Gas sold for private lights ..	17,015,060	12,666,809	+4,348,251
Gas sold for public lamps ..	1,234,438	1,074,228	+160,210
Public lamps ..	60,548	64,119	-3,571

¹ By amalgamation the companies have now been reduced to four.—Gas Light and Coke Company, paid up capital £7,615,000; South Metropolitan Gas Company, £1,881,860; Commercial Gas Company, £476,845; London Gas Company, £762,123.

The gas
com-
panies.

FIRE EXTINCTION.—Until 1893 the duty of extinguishing fires rested in the hands of the fire insurance companies, which in 1833 then formed in support of one brigade for the whole of London, but only fire kept a comparatively small establishment, in the central districts of the metropolis. The other districts were protected by small hand-engines kept up by the parochial authorities according to the 14 Geo. III. c. 78. Since the staff of the fire insurance companies was placed under the care of the Metropolitan Board, the number of stations has been increased from 17 to 53, with 4 floating stations, while 11 movable stations have also been provided, the number of engines has been increased from 11 steam and 27 manual to 3 floating engines, 38 steam land engines, and 115 manual; and the number of men has been increased from 130 to 536, in addition to 68 coachmen and pilots. The board has also undertaken the duty of protecting life from fire, which previous to 1867 was discharged by a society supported by voluntary subscription, and they at present maintain 187 fire-escapes, which are stationed during the night in the most prominent parts of the metropolis. The total receipts of the brigade in 1880 was £91,645, and the expenses £63,180, of which £66,021 was defrayed by the board, £10,000 was paid by the treasury, and £21,464 was contributed by the insurance companies, at the rate of £36 for every £100,000 insured; and then, in 1881 the expenses were over £100,000, of which over £60,000 was defrayed by rates. The number of persons endangered by fire during 1881 was 164, of whom 114 were saved and 40 lost their lives. The following table (VIII.) gives a classification of fires since 1874:—

	Number of Fires			Percentage	
	Persons	Slight	Total.	Persons	Slight
1874	254	2149	1973	10	90
1875	168	1801	1969	11	90
1876	106	1466	1572	11	90
1877	230	1974	2204	10	90
1878	170	1489	1659	10	90
1879	120	1450	1570	9	91
1880	69	1700	1769	9	91
1881	107	1994	2101	8	92

SANITARY ARRANGEMENTS.—Until 1831 no provision had been made for the construction of underground main sewers, notwithstanding that in 1290 the exhalations from the Fleet overcame the incense burnt at the altars in the neighbouring churches, and that in 1307 the river, on account of the accumulation of filth, had become inaccessible for ships. The Act of Henry III. in 1251, which provided for the appointment of a commission of sewers, was renewed in 1548 by Edward VI., and extended in its application by James I. in 1607; and subsequently separate commissions were granted as the population extended to other districts. The most important work of the old commission of sewers was the bridging over of the Fleet in 1637. In 1841 this sewer, which drained an area of over 400 acres, was widened at a cost of about £47,000, and at its mouth an iron culvert was provided which carried its discharge into the middle of the Thames. Other main sewers were constructed, but the bridging of them over was carried out slowly and in a very imperfect manner. In early times the nuisances were carried away by the scavengers and the sewage received into wells, which when full were pumped into the kennels of the streets. Until 1848 the discharge of house sewage into the main drainage was forbidden, and the construction of cesspools enforced, the majority of which were unprovided with overflow drains, but after 1810 there was considerable improvement in connexion with the introduction of better arrangements for a supply of water. Under the auspices of the Metropolitan Commission of Sewers, created by the Act of 1843, a more satisfactory system of local drainage was enforced; but its action in regard to the main sewage discharge was so dilatory that the pressure of public opinion led to the Metropolitan Local Management Act of 1865 providing for the creation of the Metropolitan Board of Works, in which was vested the care of the main sewers, and to which was entrusted the construction of works for their discharge at a distance from London regarded as sufficient to prevent the pollution of the river. Works were commenced in 1869, and completed in 1865 at a cost of £4,807,000, pro-

Metropo-
Board.

viding three lines of intercepting sewers on the north side of the river, which convey the discharge 11 miles below London Bridge, and two lines on the south side, which convey their discharge 4 miles farther down. These works comprise 80 miles of main intercepting sewers, in addition to four pumping stations to raise the sewage from the lower levels. The total length of the main street sewers entrusted to the board was about 168 miles, one-fifth of which consisted of offensive open sewers, while many of the others were of most defective design or out of repair. The total cost of repairing these sewers, and connecting them with the new main drainage system, was estimated at £800,000, and works to the value of £750,000 have been executed. The sum expended on main drainage and main sewers up to 31st December 1881 was £5,684,470. The opinion seems to be increasing that the present method of getting rid of the sewage of London is idically wrong, and undoubtedly the sewage discharge may reach proportions which may absolutely demand a new supplemental schema. For the four years ending 1878 the average daily sewage discharge was 124 millions of gallons, in 1878 it was 157½ millions, and it is now estimated at 180 millions.

THAMES CONSERVANCY. The conservancy of the Thames was in 1857 transferred from the corporation to a body of twelve, nominated by various authorities, and presided over by the lord mayor; and in 1867 the conservancy of the upper reaches from Staines to Cucklade was vested in a board, of which the conservators of the lower reaches formed the majority. Under the auspices of these two boards not only has the navigation of the river been very much improved, but very stringent care has been exercised to prevent its unnecessary pollution. In 1868 the Len was also placed under the control of a conservancy board. The expenses of the boards are defrayed by tonnage dues, tolls, pier dues, fines, and licences, and contributions from the canal and water companies.

Street sanitation. The sanitary condition of the streets and houses is under the care of vestries and district boards, but great variety exists in regard to the efficiency with which the work is performed.

Cemeteries. An Act passed in 1846 provides for the prohibition of interment in any of the cemeteries within the metropolitan area by order in council, and forbids the construction of new burial grounds within 2 miles of the metropolis except on the approval of the secretary of state. The power of constructing cemeteries for such several districts is granted to the vestries, who may borrow money for the purpose from the Public Works Loan Commissioners, and are required to appoint a board for their management. The commissioners of sewers for the City of London are the burial board for the City parishes. The secretary of state has the power to issue regulations in regard to the construction of cemeteries and the arrangements connected with interment. Among the more important suburban cemeteries are Kensal Green (in which many eminent persons have been interred), Brompton, Hampstead, Highgate, Abney Park, Nunhead, and Norwood.

Climate. **HEALTH.**—Apart from the deleterious influence of smoke and defective sanitary arrangements, London must be

regarded as exceptionally healthy. Although subject occasionally to rapid alternations of temperature, the climate is generally mild and according to the seasons equable, with an early spring and a long autumn. The following table (IX.) gives a summary of Greenwich meteorology for thirty-two years, 1849-80.—

Weekly Movement of Air in Miles.	Yearly Fall of Rain in Inches.	Mean Dryness of Atmosphere.	Mean Temperature for the Year.	Mean Temperature for Quarters ending in—			
1811	54.8	89.9	45.8	March	June	Sept.	Dec.
	54.8	89.9	45.8	59.7	59.4	54.1	

In 1306, when the population did not exceed 50,000, Smoke the citizens of London petitioned Edward I. to prohibit the use of sea coal, and he passed a law making the burning of it a capital offence. John Evelyn, in *Fumifugium*, written in 1661, complains that on account of the increase of coal smoke the gardens no longer bear fruit, and instances various cases in which the smoke had been prejudicial to health, but the influence of smoke in increasing fogs and intensifying their evils seems not to have been appreciable. The smoke producing area has since then increased from about 3 square miles to over 100 square miles, and the average daily consumption of coals in domestic fireplaces has mounted to about 27,000 tons, or in winter probably to 40,000 tons, which in certain states of the atmosphere produces a cloud of smoke resting for days over the central districts of the town, and shutting out the sun, even when it does not descend in foggy weather as a thick, impenetrable, and partly poisonous mass of darkness. During the fog of 1879-80 asthma increased 220 per cent. and bronchitis 331 per cent., and in the week ending February 13, 1882, the death-rate, owing to the dense fogs, rose from 27.1 in the previous week to 35.3, diseases of the respiratory organs rising to 994, the corrected weekly average of this class of diseases being 430. The evil is mainly due to the smoke of domestic fireplaces.

The death-rate of London has steadily declined since the beginning of the century, when it was first exceeded by the birth-rate. A record of the births and deaths of London entitled "Bills of Mortality" was made by the parish clerks in the plague year of 1593, and from 1603 was continued even after the returns had begun to be published by the registrar-general. Though they only included the births of persons baptized according to the forms of the Church of England, and the deaths of persons buried in consecrated ground within the parishes included in the "Bills," and were in many cases very carelessly compiled, they place it beyond doubt that even in years when London was exempt from the plague the rate of mortality required a large immigration from the country to take the place of those who died in London. Previous to 1593 the great plague years were 1349, 1361, and 1369.

The following table (X.) shows the number of births and deaths in the great plague years of the seventeenth century, and the average annual number for every decade in the 18th century.—

Years.	Total Deaths.	Deaths from Plague.	Births.	Excess of Deaths.	Average 10 Years ending—	Deaths.	Births.	Excess of Deaths.	Average 10 Years ending—	Deaths.	Births.	Excess of Deaths.
1609	17,864	10,889	4,081	13,822	1710	21,461	18,028	3,433	1790	22,001	17,106	4,895
1610	42,043	34,288	4,758	37,532	1720	22,809	17,111	5,698	1770	24,948	19,784	5,164
1611	64,286	56,417	6,781	57,636	1730	24,208	18,268	5,940	1780	22,521	18,268	4,253
1612	28,880	10,400	6,232	22,648	1740	20,422	18,889	1,533	1790	22,001	21,477	524
1613	67,206	38,396	6,247	60,859	1750	24,467	22,806	1,661	1800	24,372	22,608	1,764

The average mortality of London in 1881 was 21.8 per 1000, or 1.1 less than that of the twenty other large towns of England, while the rate for England was only 20.4. It is to be remembered that London contains a comparatively small proportion of working class population. Its sanitary condition is still very far in advance of that of Paris, where at present the death-rate is about 180 for 100 in London. The registrar-general calculates that according to the density of London its normal death-rate should be much lower than

it is, but, besides the fact that mortality is influenced by other causes than sanitary arrangements, the extended area augments the evil results of density, and the lesser density in some districts cannot counterbalance the excessive crowding of others. Table XI. gives the annual rate of mortality per 1000 persons living for various periods, and Table XII. the number of births and of deaths from the principal zymotic diseases and from all causes.—

Central
meat
market

The Central London meat market, opened in Smithfield in 1868 at a cost of about £250,000, to supersede Newgate market, is built in the Italian Renaissance style, with towers at the four corners, and occupies about 3 acres, its length being 625 feet and its breadth 240. Below the market area there is a railway terminus. To the west of the meat market another one-third its size was opened in 1875 for poultry and provisions. From 1869 to 1876 the toll received from the meat market increased from £14,280 to £18,275, or 281 per cent, and with the addition of the poultry and provisions market it had increased in 1880 to £21,310, or 71 per cent. The total amount of meat sold in the market in 1879 was 215,614 tons; in 1880 the total amount was 221,446 tons, of which 107,926 tons were country-killed, 80,905 town-killed, 7381 foreign, and 22,830 American, the amount of American meat in 1876 being only 6515 tons. A large quantity of meat is conveyed to the butcher's direct without entering the market, and several butchers also buy their cattle and get them killed privately. As, moreover, the cattle markets and the meat market supply towns and villages beyond the metropolitan area, there is a double impossibility of forming from these sales a true estimate of the actual amount of butcher's meat consumed in London.

Leaden-
hall
meat
market.

Leadenhall, which according to Stow belonged in 1300 to Sir Hugh Neville, and had been used as a market before it came into the possession of the city in 1411, was enlarged in 1444 by an addition for a grain market in connection with the wool market, and its removal to its present site, the cloth market also following before 1503, and before 1553 the foreign butchers who formerly stood in the High Street off Lime Street had been ordered to take stalls in it. A great part of it in the time of Stow was used as a wool market, but afterwards it became the principal provision market in the city, and, in 1600, to Fennell, the Spanish ambassador, that Charles II. felt that he believed there was more meat sold in that market than in all the kingdom of Spain. The Leadenhall underwent improvements in 1718 and 1814; and in 1881 a new structure of elegant design, with an area of 26,900 square feet, and erected at a cost of £26,000, was opened as a market for fowls and game, the principal commodities sold at Leadenhall for many years.

Billings-
gate

Billingsgate, the great fish market of the metropolis, was from an early period a harbour for small ships and boats, and in the time of Stow had almost superseded its great rival Quenchinbo, which was in the possession of the Crown. As it grew in importance fish stalls were erected in its neighbourhood, but the original market for fish was in Fish Street, and Friday Street, Chesapeake, which received its name from being inhabited by fishermen who served Friday's market, is mentioned as early as 1303. The Act of 1699, which made Billingsgate a "free market for fish," to some extent interfered with the ancient control of the fishermen, although the custom of selling fish there had been introduced long previously. Until 1846 Billingsgate was a mere assemblage of wooden sheds. The building erected in that year was succeeded by another in 1877, with an area of 39,000 feet instead of 20,000; but on account of the deficiency of its communications and the defective layout accommodation and arrangements, the market is totally inadequate. Among several abortive efforts to establish other markets for fish was Columbia market, which was completed in 1869 by the Barons Burdett Courts for over £200,000, and presented as a fish market to the City, but failed to attract attention. The City authorities have the intention to utilize the vegetable market in course of erection at Smithfield as a fish market, and a scheme is also being promoted for a fish market in the parish of St Paul, Shadwell. A fish and vegetable market has been established by the Great Eastern Railway Company at Canning Town. The quantity of fish brought to London by rail is not given by the statistics commencing prior to 1868, but in 1846 the quantity brought by water alone was 106,739 tons. In 1868 the total brought by water and rail was 192,004, in 1870 it was 117,192, in 1875 only 94,649, but since 1877, when the new market was opened, it has gradually increased from 107,168 to 130,629, or nearly 2000 tons less than in 1866, and scarcely 15,000 more than were brought in 1846 by water alone. There has of

late years been a more rapid increase in the quantity of water home fish, but the amount brought by rail is at present about two-thirds of the whole. Thus, with a population which since 1861 has increased by two-fifths, the fish supply has practically remained stagnant while, owing to delay in consequence of increased pressure of traffic, the fish often deteriorate so as to be unfit for human food.

Covent Garden market, for vegetables, fruit, and flowers, which Covent occupies the site of a convent garden belonging to Westminster Abbey, seems to have been used as a market very early in the 17th century, and it received a considerable impulse from the discontinuance of Stocks market on account of the building of the Mansion House and also of Honey Lane market, which in 1823 was succeeded by the City of London school, while since the removal of Hungerford market to make way for Charing Cross station it has remained the only vegetable and flower market of importance in the metropolis, although vegetables of a cheap kind are sold at the Borough and Spitalfields markets, watercresses at Farringham market, which superseded the Fleet vegetable market in 1824, and potatoes at the station of the Great Northern Railway. Until 1823 Covent Garden market consisted of an unsightly array of sheds. The present building, erected by the Duke of Bedford, though lately much improved, is quite inadequate for its requirements, while the arrangements for the disposal of mud and refuse are very reprehensible.

Tattersall's, Knightbridge, established by Richard Tattersall in Tattersall's, one of the principal markets in London for riding and milch, carriage horses, and may be regarded as the headquarters of the turf.

One of the principal difficulties connected with the establishment of new markets in London lies in the inconvenient railway arrangements, which render it impossible to obtain a site that shall have easy access to the metropolis and direct communication with the several districts of England and with the Continent. The poorer classes obtain a considerable supply of vegetables and other provisions from costermongers' mangers, and itinerant vendors, who either occupy stands in special localities, especially in the East End, and in High Street (Brixton), Hampstead Road, Edgware Road, and York Road (Barnes Town), or hawk them through the streets. The capital possessed in 1882 by these vendors, who then numbered 41,040, was estimated at £40,000, their gross amount of annual trade at £3,700,000, and their annual gains at £900,000. Since that period their numbers, capital, trade, and gains have probably increased at least one-fourth.

COMMERCE AND INDUSTRY.—London, which was a port ^{London} ^{com-} ^{merce} of some consequence in the time of the Romans, is spoken of by Bede as the "mart of many nations resorting to it by sea and land." The Hanse merchants, protected by a clause of Magna Charta, began in the 13th century to frequent London in large numbers, and, after obtaining liberty in 1236 to land and store the wool imported by them, are supposed to have settled in the Steelyard about 1250, but as early as the 8th century they had begun to frequent Billingsgate, and in 978 King Ethelred had conferred certain privileges on them and on other traders. Probably by the time of Fitzstephen London had become the most renowned mart of the world, with the exception perhaps of Antwerp and Bruges. The foreign merchants received a special charter from Edward I. in 1303, and, notwithstanding occasional interference with their privileges, the Hanse traders, who had erected extensive factories and storehouses near their "Gildhall," gradually absorbed the greater portion of the foreign trade of London, until the incorporation of the Merchant Adventurers of England, in 1505, for trading in wool to the Netherlands. The trade with the Levant, which had

become of some importance in the 15th century, soon largely extended, and commercial intercourse was also opened up with Barbary, Guinea, and Brazil. After the abolition of the special privileges of the Steelyard merchants, the trade in wool was transferred almost entirely to the Merchant Adventurers, the annual export of English wool and drapery to Antwerp and Bruges in 1666 being estimated at over £2,000,000. The close of the 16th century was marked by the rapid extension of maritime discovery, and the spirit of enterprise was stimulated by the grant of monopolies to those companies which should first open up communication with undiscovered countries. One of the earliest and most successful of the great maritime companies was the *Rasasin*, incorporated in 1553, which, besides establishing an extensive commerce with the ports of Russia, had an overland trade with Persia. The foundation of the Royal Exchange by Gresham in 1566 marked an era in the commercial history of London; and the destruction of Antwerp by the duke of Parma in 1585 left it without a rival as the emporium of Europe. The settlement of many of the *Flinders* merchants in England gave a great impetus to the manufacture of silks, damasks, and other fine cloths, but from the time of the expulsion of the Steelyard merchants by Elizabeth in 1597 the development of the maritime trade of London was solely in the hands of English companies. The incorporation of the Turkey Company in 1579, of the East India Company in 1600, of the Virginia Company in 1606, and of the Hudson's Bay Company in 1670 must be regarded, not only as the most important events connected with the growth of the port in the 17th and 18th centuries, but as of prime consequence in relation to the social and political history of England.

Present

trade.

In the trade of London there is a large excess of imports over exports, arising from the fact that it is specially a mart, and is removed from proximity to any large manufacturing district. The value in 1880 of the total trade of Liverpool, £191,489,888, was nearly equal to that of London, which was £194,043,836, but the value of the imports of London exceeded those of Liverpool by nearly £34,000,000, while the exports of Liverpool exceeded those of London by about £31,000,000. London has almost a monopoly of the trade with the East Indies and China, and has thus become the chief emporium for tea, coffee, sugar, spices, and indigo, and for silks and Eastern manufactures. A great part of the overland trade of London with India has till quite recently been carried on via Southampton, which, and also Folkestone, Newhaven, and Dover, may be regarded as virtually ports of London. The value of the imports of Folkestone, Newhaven, and Dover in 1880 amounted together to £24,485,034, and their exports to only £4,433,244; the imports of Southampton were valued at £9,305,183, and its exports at £9,306,926. In the Mediterranean and Levant trade London has now a powerful rival in Liverpool. From European and Asiatic Turkey London imports corn, dried fruits, madder, and various other special products; from Greece currants and olive oil; from Italy olive oil, wine, sunscho, oranges, and lemons; from Spain wine and dried fruits; from Portugal and the Azores oranges and wine. Nearly the whole of the French trade with England is concentrated in London, the imports including all the special French manufactures, and large quantities of butter, eggs, vegetables, and corn. It is, however, largely carried on through the southern ports, the value of the imports of silk

to Folkestone in 1880 being £3,614,014, and those of London only £260,646, while the imports of eggs at Newhaven greatly exceed those of London, as do also the imports of butter and eggs at Southampton. London absorbs the greater part of the Baltic imports to England, especially timber, corn, cattle, wool, and provisions, the tonnage of the shipping that entered from Germany in 1881 being 654,741, from Belgium 249,181, from Sweden 418,997, from Norway 201,056, from the northern ports of Russia 401,076, and from Denmark 135,634. The tonnage that entered from the southern ports of Russia only amounted to 50,883, but much of this trade is carried on *via* Southampton. The chief imports from Russia are corn, tallow, timber, hemp, linseed, and wool. The fact that the staple manufacture of Lancashire is cotton has enabled Liverpool to gain a superiority over London in the United States trade, with the exception of imports of tobacco from Virginia; but the shipping that entered London from the Atlantic ports of the United States in 1881 had a burden of 670,079 tons, and from the Pacific ports of 3248 tons. From Central America London obtains its chief supply of the finer woods, and also jalap, sarsaparilla, indigo, coffee, and Peruvian bark, and from South America sugar, hides, indiarubber, coffee, diamonds, and various drugs. From Canada the port receives timber, corn, cattle, and provisions, from the Australian islands wool, oil, gold, copper, tin, provisions, and cattle; and it possesses more than half the trade of England with the West Indies, the principal imports being sugar and molasses, fruit, rum, coffee, cocoa, fine woods, pimento, and ginger.

On account of the burning of the records at the custom-house, and the absence of regular parliamentary returns, it is impossible to give a continuous summary of the progress of the shipping trade since 1810, and the following table (XV) gives the returns of the shipping trade engaged in the foreign and colonial trade in various years from 1685 to that date, and the yearly average for subsequent periods:—

	Entered Favourable		Clearer	
	Vessels	Tonnage	Vessels	Tonnage, &c
1683	..	117,887	..	191,009
1674	..	139,872	..	217,840

1881	13,765	2,810,043	5,011	6,476,000

Since 1873 vessels with sails and masts have been included in the coasting trade, and therefore the figures after that date show trade much greater progress than has actually taken place. In 1750 the number employed was 6306, and in 1795 it was 11,065 of 1,176,400 tons. The following table (XVI.) gives details from 1855:—

	Entered		Clearer	
	Vessels	Tonnage	Vessels	Tonnage

Values of exports and imports.

Deduced values of the exports from London have been made at various periods, and are now made annually in the statement of the value of the United Kingdom. Since 1840 the value has more than quadrupled, being in that year £11,536,087, from which it gradually rose almost without intermission till it was £20,232,118 in 1874, but from that year it declined till in 1879 it was £17,336,763. In 1880 it again rose to £22,600,920, considerably above the average of the four years 1876-79, which was £18,684,473, but as much

below the average of 1872-76, which was £27,144,450. No return of the value of the imports is given before 1872, when they were £134,174,141. The value for 1880, £141,442,907, exceeds that of any previous year, the next being that for 1877, £140,832,773, while the average for 1872-76 was £129,443,956, and for 1879-79 £139,434,773. The following table (XVIII.) gives details of the principal imports for 1880 and 1880, and also a comparison with the United Kingdom in regard to the same articles—

Principal Articles.	1880		1880

Docks.

In the time of Stow, Billingsgate had begun to supersede Quenchin as the principal landing place of the port of London, but he also gives a list of other "common waterways," and mentions that there were besides "divers private wharfs and keys all along from the east to the west end of the city, where merchants of all nations had landing places, warehouses, cellars, and storages of their goods and merchandise." On account, however, of the attempts made to avoid the payment of customs by the use of private landing places, a royal proclamation of Elizabeth appointed certain quays to be used as general landing places and others for special purposes. After the great fire the limits of the port were declared to be the North Foreland and London Bridge, certain wharves named "legal quays" were appointed for the general trade, and others named "special wharves" were permitted to be used under certain conditions with the special leave of the commissioners. The frontage of the legal quays in 1796 was only 1419 feet, and of the special wharves about 8500 feet, and so small-made was the storage accommodation that it would not have sufficed even for the single article of sugar. After the proposal for the establishment of a set docks was made by the West India Company the system was very rapidly extended. The West India docks at the Isle of Dogs were opened in 1806, the London docks at Wapping in 1806, the East India docks at Whitehall in 1808, St Katherine's docks to the east of the Tower in 1828, the Victoria docks in 1850, and the Millwall docks at the Isle of Dogs in 1868. The West India Company was granted for twenty years a monopoly of the West India trade, the London Dock Company of the trade in wine, brandy, tobacco, and rice, and the East India Company of the East India and China trade, but in no case were the privileges of the companies renewed. The various docks have at different times undergone improvement and extension to meet modern necessities, the latest addition being the Albert extension of the Victoria dock, opened in 1880, which affords an additional water space of 70 acres, and is unsurpassed in the completeness of its arrangements by any other dock in the world. The St Katherine's, London, and Victoria and Albert docks are now held by one company, and the East and West India docks by another, who are adding to their accommodation by the construction of the Tilbury docks specially for ocean steamers. All the great merchandise docks are thus on the north side of the river,—

the Commercial docks, which date from 1696, and were reconstructed in 1807, and the Surrey docks (1813), on the south side of the river, being used almost exclusively for timber and grain. The position of St Katherine's docks renders it impossible to adapt them to modern requirements; and probably, on account of the increased use of large ocean steamers, all the older docks may soon be superseded as regards the bulk of the foreign trade. The water area of the docks on the north side of the river, which in 1861 was 272 acres, will soon be 465 acres. The Surrey and Commercial docks, which is very complicated in its construction, has a total area, including land and water, of 530 acres. The land and water area (in acres) of the several docks on the north side of the river of recent completion or in process of construction is as follows (Table XIX.)—

Docks.	London	St Katherine's	East and West India	Victoria	Albert	Millwall	Tilbury.	Total.
Water	40	10	120	375	88	70	440	
Land	18	18	210	610	200	400	1,473	
Total	58	28	330	985	288	470	1,913	

The bonded warehouse system was sanctioned in the port of London in 1808, and the exclusive enjoyment of the several parts of this house privilege gave it a great advantage over the other parts of the kingdom. The warehouses of the dock companies, each occupied with their special class of goods, embrace a large portion of the City area, but the rapidity with which goods now pass into consumption renders this kind of dock property almost very unprofitable, and it is probable that very soon many of the warehouses will be turned to other uses.

The Custom-House in Lower Thames Street was built by Leing, Custom 1814-17, but on account of the enlargement of the central part the house, present Corporation House, 480 feet in length, designed by Smith, was afterwards added. In the building there is a museum containing various old documents and specimens of articles seized by the custom-house authorities.

Trinity House, Tower Hill, a plain building with an ornamental Trinity facade, erected in 1798 from the design of Wyatt, is the seat of an House association of mariners which received a charter from Henry VIII.

in 1514, and gradually acquired the management of lighthouses and buoys not only on the Thames but on the whole English coast, along with the superintendence of naval arsenals and dockyards. Besides the corporation of the City it had the conservancy of the Thames, until those authorities were superseded by the Thames Conservancy Board. Its general rights and privileges have also been much curtailed since 1853, when it was put under the partial control of the Board of Trade, but it has still the sole charge of the erection and maintenance of lighthouses and buoys, the examination of pilots and of navigating lieutenants, and two of its elder brethren act as naval advisers in the High Court of Admiralty.

The City.

The power of that portion of London known as the City is largely due to its proximity to the port, but the rapid development of the trade of the port is closely connected with the increase of London outside the City limits, which is of course dependent on a great variety of causes. The uninterrupted extension of the business and financial transactions of the City, and the connection of these with the rapid increase of the surrounding population, is sufficiently evidenced by the fact that the rateable annual value of the City has risen from about £700 an acre in 1801 to about £5300 an acre in 1881, that the net profits under the commercial and mercantile schedule D for the combined boroughs of the metropolis (1870-80) amounted to £1,088,368, of which the profits for the City alone amounted to £285,424, a larger sum than that of the whole seventeen next largest cities and towns of the United Kingdom, and that the number of persons entering the City daily during the extreme hours of business has increased from 657,379 in 1866 to 789,640 in 1881.

Ex-

changes. The business centre of London is the Royal Exchange, which occupies a commanding position between Threadneedle Street and Cornhill, at the principal convergence of the City thoroughfares. The first building, erected 1667-70 by Sir Thomas Gresham and presented to the city, was destroyed by the great fire, and the second, opened in 1699 was also burnt in 1838. The present exchange (1839-44), designed by Tite and erected at a cost of £180,000, is a quadrangular structure with an imposing Corinthian portico at its principal entrance, and encloses a court surrounded by an ambulatory. It is in the middle of the court that the commercial transactions take place—the ground floor being occupied by shops and offices, and the principal floor by insurance companies and "Lloyd's rooms." The principal exchanges for special articles are the corn exchange in Mark Lane, where the privilege of a bar was originally granted by Edward I. to wool exchanges; Coleman Street, the second exchange adjoining the custom-house, erected in 1646 in the Italian style, and consisting of a rotunda surrounded by a dome, and the auction mart for landed property in Tokenhouse Yard. The metal market is a very important one; and this is also a very large congregation of precious metals and diamonds, the vendors in which are chiefly concentrated in the neighbourhood of the Mint.

The Mint.

The Royal Mint, Tower Hill, erected in 1805 on the site of the Cistercian abbey of St. Mary, is the only mint in England for the fabrication of gold and silver coins, but bronze coins are chiefly made at Birmingham, and gold coinage is now also manufactured at Sydney and Melbourne.

Banking.

The unique commercial position of London, and its intercourse with every quarter of the globe, have assisted to make it financially a more complete centre than it is commercially the metropolis of the world. The stock jobbers and brokers, who according to the City census of 1861 numbered 1832, and who have their offices chiefly in the courts and alleys adjoining the Bank of England and the Royal Exchange, are nearly all members of the stock exchange, for whom the present building in Capel Street was erected in 1801; but there is also an open stock exchange in Leadenhall. The great approximation to banking transactions in London appeared in the negotiations for loans between Rishelwell and the principal city merchants, but the general adoption of the system was due to the civil war, when the merchants, some of whom had already made use of the Royal Mint as a bank of deposit, and the landed proprietors, began to place their money for the sake of greater security in the hands of the goldsmiths. Some of the private banks now existing, such as Coutts's and Child's, date from the 17th century, and a new era in the financial history of London was inaugurated in 1694 by the foundation of the Bank of England, of which a full account is given in the article BANKING (vol. iii. p. 315 &c.). Until 1788 the business of the bank was carried on at Grocers' Hall. The present building, which covers about 4 acres, and was enlarged in 1776 and 1788 by Sir Robert Taylor and Sir John Soane, presents to the street a low triangular wall without windows, and almost entirely devoid of ornament except at the north-west corner, where we caught from the temple of the Sibyl at Tyrol. Until the establishment of the Bank of London and Westminster Bank in 1826, the Bank of England was the only joint-stock bank in London. The private and joint-stock banks which have offices in London now number over 150. The principal banks are members of the Clearing House near Lombard Street, where a daily clearing of drafts and cheques is effected. For the year ending April 30, 1882, the total amount of bills, cheques, &c., paid at the

Clearing House was £6,882,645,000, the largest sum paid in any of the fifteen years for which statistics have been collected, the amount for the first year ending 1868 being only £3,557,411,000. The extent of the commercial enterprise of London is strikingly indicated by the large number of companies, with their field of operations chiefly in foreign countries, which have been projected in the City or have in at their headquarters. The foreign operations of these companies are however sometimes only nominal, their real business being wholly confined to London itself.

The largest manufacturing industry in London is that of brewing. The number of common brewers in 1880 being 110, who made up of 9,955,177 bushels of malt, while of the 412,192 barrels of beer exported from the United Kingdom 236,206 were from London. To supply the breweries with water, wells now require to be sunk below the chalk to the greensand. According to Stow, the brewers in 1585 in London and Westminster, who then consumed "water to the friendly water of Thames," numbered 26, some of them being foreigners, who first introduced the art of cultivating hops. Among the oldest and most important of the breweries now existing is that of Barclay, Perkins, & Co., which covers an area of 12 acres, begun at one time to Johnson's friend Thames, and occupies the site of the Old Globe Theatre.

Silk-weaving, which received a special impulse from the settlement of foreign refugees at Spitalfields after the revocation of the edict of Nantes, has within the last fifty years been in a stagnant condition, owing chiefly to the rivalry of Lancashire. The majority of the other manufactures are centred on in the neighbourhood of the Thames. The ships built in London in 1881, which are principally yachts, numbered 64, but their total tonnage was only 2723. The principal shipbuilding yards are at the Isle of Dogs. Boat-building is extensively carried on at Chelsea and at several other places in the upper reaches of the river. There are large engineering-works at Lambeth and Millwall, potteries and glass-works at Lambeth, Whitefriars, and Southwark, tanneries at Brompton, chemical-works on the Lea, paper-works on the Wandale, and sugar bakeries at Whitechapel. The clothe-making shops are situated principally in the neighbourhood of Roper's Row, but there are several adjoining Tottenham Court Road and the Strand, where upholstery warehouses are very numerous. Linen making gives employment to a large number of women and children in the eastern districts. There are extensive hat-manufactures in Lambeth. The special manufactures in different parts of London are too numerous for mention. The principal layers of the metropolis are in Long Acre. A large trade in second-hand clothing is done by the Jews at Houndsditch, especially on Sunday morning, and on the same day of the week there are bird and fancy animal fairs at Church Street, behind Green, and at St Andrew's Street, Brompton, near the Seven Dials. The centre of the cloth-trade is in Tottenham Court Road, but the great majority of the cloth-makers have their premises in the neighbourhood of Covent Garden and still farther west. Fleet Street is largely occupied with the offices of the London and the provincial daily newspapers, but the office of the *Times* is in Printing-house Square. The weekly newspapers have their offices chiefly in streets running off the Strand.

PAUPERISM.—London since 1867 has been divided into thirty poor-law unions, which are governed by boards of guardians, for whose the most part elected annually by the householders and owners of property, the number of votes possessed by each owner or household varying from one vote, according to the value of the property. A proportion of the guardians in each union are so elected, or are nominated by the Local Government Board. The Act of 1867 authorized the establishment of outdoor pauper-relief in any union or parish; and in twenty-seven of the thirty unions of the metropolis there are now forty-seven of these dispensaries, the number of prescriptions made up in the year ending March 31, 1882, being 1,000,000. For the maintenance of lunatics and insane poor, patients suffering from contagious diseases, and of pauper children at school, and for the relief of casual paupers, a metropolitan common poor fund is provided, through the operation of which the cost of maintaining the poor is now equalized, to the extent of 42½ per cent. of the whole sum expended over the metropolitan area. The good results which have followed, both in lessening expenses and in diminishing pauperism, especially outdoor pauperism, form a strong argument for the complete equalization of the rates, and the creation of a united poor-law authority for the whole metropolis. The three unions which in 1860 contained more than an out of the poorer ones were Kensington (£227,705), St. George's (£235,586), and the City of London (£261,080); and the three unions most benefited were Holborn (£21,048), Bethnal Green (£19,536), and St. George's, Southwark (£23,066); but, as will be seen from Table XXI. below, great inequality still exists in the rating, and this rate is generally higher in the poorer districts. The poor-law union possesses one or more workhouses, but the accommodation is inadequate, and difficulty in dealing satisfactorily with applicants often follows. Several unions, by the powers granted them under the Act of 1867, have combined into districts to provide infirmaries for the sick and imbecile, there being now only three unions—

Beltham Green, Hampstead, and Letcham—whose sick are not treated in establishments under medical supervision. In addition to this, the several unions and parishes are combined into one metropolitan asylums district, with a managing body of sixty members, fifteen of whom are nominated by the Local Government Board. The total number of persons relieved in establishments belonging to the managers of the metropolitan asylums district since the first was opened in 1870 has been more than 1200 in insensible asylums, nearly 50,000 in hospitals for infectious diseases, and 187,000 in the "Exmouth" training ship, which was established in March 1875. The paupers' schools fall to be noted under another section (see below, p. 834). The amount of accommodation provided in the various establishments of the unions in July 1870 was 35,093 beds, and in December 1880 it was 53,332 beds. Table XX gives a summary of the poor rate returns for 1880, Table XXI. the rateable value of the different unions in 1871 and 1881, and the

average pauperism, the amount of adjusted relief, and the rate in the pound for relief in 1880; and Table XXII various particulars in reference to metropolitan pauperism for 1871 and 1880.

The annual income of the various charitable institutions in Charities. London is now over £4,000,000, of which at least three-fourths is spent in London. That of the endowed parochial charities of the City of London in 1885 was £34,500, which by 1881 had increased to £116,900, those of Westminster being in the same years £26,555 and £33,124. The income of the charities of the Livery Companies in 1869 was stated to be £49,027, and now the 1,023 charities belonging to the companies have an aggregate income of £188,829, representing a capital value of £24,456,758. The amount spent on education in £68,130, and on doles £108,468. In addition, the charities of the corporation probably possess an annual income of £30,000. The parliamentary commission appointed to inquire into the endowed parochial charities of the City of London and

TABLE XX.—Summary of Poor Rate Returns for 1880

From Poor Rates	Receipts		Expenditure

Westminster in the report of 1880 divides them into two classes—those that are elementary and those that are ecclesiastical. In regard to the first, it states that it is impossible to effect a satisfactory combination or readjustment of them under existing circumstances, and, in regard to the second, that they are so far hindered by altered circumstances as to require reappropriation to new charitable use.

Police. CRIME.—The London police district, or "Greater London," is divided into two police jurisdictions, that of the metropolitan police, with an area of 440,918 acres, and that of the City police, with an area of 488 acres. The Metropolitan police force, which suppressed the night watch in 1850, owes its existence to a bill introduced by Sir Robert Peel, providing for the establishment of a Metropolitan police under the control of the executive government. In 1839 the old watch was abolished within the City limits and a City police force appointed, which, however, is entirely under the control of the common council. There are two police courts within the City district, viz., Guildhall and Mansion House; and thirteen within the Metropolitan district, viz., Bow Street, Clerkenwell, Great Marlborough Street, Marylebone, Westminster, Lambeth, Southwark, Thames (Steynes), Wapping Street, Woolwich, Greenwich, Hammer-smith, and Wandsworth. The headquarters of the Metropolitan police are at Scotland Yard. The expenses of the two City police courts in 1880 were £10,031, and those of the Metropolitan police courts were £269,005, of which £10,637 was defrayed by fines and forfeitures. The Metropolitan police have power to regulate the street traffic, to inspect and license cabs, omnibuses, and other public conveyances, to interfere in abating noxious nuisances, and to inspect common lodgings. From 6158 in 1861 the Metropolitan force had in 1880 increased to 10,948, or one to every 430 of the population, the City police force from 628 to 880, or one to every 61 of the population. The increase of the City police force is necessitated wholly by the in-

crease in the number of persons who daily frequent the City, for not only has the night population greatly diminished, but the resident criminal population has become almost extinct. The number of persons belonging to the criminal classes in the whole police district of the metropolis in 1880 was 2389, as one in 1932 of the population in 1881; the number of known thieves 1885, the number in England being 17,907, the number of indictable offences was 17,835 (of which 1187 occurred in the City), the number in England being 63,437; and the number of apprehensions 5261 (City 412), the number in England being 23,231. Of indictable offences 48 were murders, 6 attempted murders, 418 attempted assaults, 1160 larcinages, 8913 simple larcinages, 1745 larcinages from the person, and 867 witnesses of counterfeit coin, 47 bodies of persons found dead and unknown were photographed and not identified. The number of offences determined summarily within the area of the Metropolitan police district was 125,302, or 11 1/2 to every policeman, the proportion of indictable offences to every policeman being 8-70. The number of offences determined summarily within the City area was 5649, or only 70 to every policeman, while the proportion of indictable offences was only 78. The total expense of the Metropolitan police was £1,165,661, or about 11s 10 1/2 per man, £461,824 was contributed to the expense from public authorities, and £38,071 was received for special services. The expense of the City police, £90,662 in 1880, is defrayed wholly by rate, and the cost per man is about £109.

The following table (XXIII.) gives details regarding police and crime in the Metropolitan police district since 1871, to which it will be seen that, although compared with the increase of population the total number of apprehensions has diminished, there has of late years been a considerable increase in the number of larcinages, and that the amount of property lost by thieves has been increasing very seriously.—

Prisons. The Newgate and Holloway prisons are in the hands of the Court of Aldermen. Newgate, rebuilt after the riots of 1780, is now no longer used for persons awaiting trial in the Central Court. The City prison, Holloway, which is the House of correction for City prisoners, was erected in 1861 at a cost of nearly £100,000. Brixton, which occupied the site of a royal palace, and was granted to the city as a house of correction by Edward VI., was discontinued in 1864, the old Fleet prison was abolished in 1844, its site being now occupied by the Memorial Hall of the Congregationalists; Horse-monger Lane prison was superseded by Wandsworth prison, and Marshalsea in Southwark, immortalized by Charles Dickens, had been discontinued long before he wrote. The house of detention for Middlesex is Clerkenwell, and its houses of correction are Coldbath Fields for male prisoners and Westminster for females. Wandsworth is the prison for Surrey. The convict prisons within the metropolitan area are Brixton, Millbank, Pentonville, Wormwood Scrubs, Woking, and Fulham.

Elementary schools. RETROACTION.—Until the constitution of a School Board for London in 1870, the only special organizations for providing education to the poor children in London were the British and Foreign School Society, founded in 1818, and the National Society, founded in 1811. Many of the parish schools became amalgamated with those of the National Society, but the united efforts of these societies, and also of the Church of England, of the different denominations, and of various prominent charitable institutions, failed so completely to meet the necessities of the rapidly increasing population, that in 1851 the total number of scholars attending public schools was only 167,998, and that in 1871 the returns of the voluntary schools showed that there was accommodation for only 262,265 children, or 89 per cent. of the estimated population of school age. By October 1881 the School Board had supplied accommodation for 286,094 children, which with that in voluntary schools gives a total number of places sufficient for 568,096 children. In addition to which schools are in the process of erection for upwards of 100,000 more. Up to August 1881, 8338 children were board sent to industrial schools at the instance of the board, and the board now possesses three industrial schools under its own management. The total number of children attending workhouses, separate, and parochial and district schools in 1880 was 35,223, the amount paid to teachers in these schools being £37,110. The total

expenditure of the School Board for the year ending 31st March 1881 was £1,236,360. The amount paid by the council and by the ratepayers in 1881-82 was £276,570, the rate in the pound being 6 1/2d, a rate that for 1880-81, which was 6 1/2d, but its actual productivity there may for some years be a slight increase. The average cost of the 5129 teachers in 1880 was £124. The gross cost per child has risen from £2, 4s. 9d. in 1874 to £2, 17s. 6d. in 1881, but this will probably be a considerable diminution when the schools become fully occupied throughout a whole year. The following table (XXIV.) gives a comparison of cost between the board schools and other schools of London and of England in 1880.—

Fitzsimmons mentions that in his time the three principal churches (transgressed by ancient privilege and dignity ecclesiastical schools, and that other schools were permitted on sufferance. The churches schools, referred to are supposed by Stow to have been St Paul's Cathedral, St Paul's at Westminster, and St Saviour's, Bermonsey, in Southwark. The various other parishes and churches, which were afterwards founded, had each its school, though of less fame than the earlier ones. On account of the suppression of the alien priories and religious houses by Henry V., Henry VI. in 1445 founded grammar schools at St Martin's-le-Grand, St Mary-le-Bow, St Dunstons in the West, and St Anthony's, and in the following year others in St Andrew's, Holborn, All Saints, the Great St. Peter's, Cornhill, and in the hospital of St Thomas of Acon. The custom of school disputations mentioned by Fitzsimmons was continued till the time of Stow, who states that they were restrained on account of the quarrels between the boys of St Paul's and St Anthony's. In his time the principal schools "referring to these

exercises" were St Paul's, St Peter's (Westminster), St Thomas of Acon, and St Anthony's. The last-named, which commonly presented the best scholars, and at which Sir Thomas More, Lord Chancellor, Heath, and Archbishop Warham received their education, had, however, lately greatly decayed. Up to the time of the dissolution of the monasteries education in England had been in the hands of the religious houses, but, though many of the grammar schools in London were then disestablished, several were re-erected and re-endowed, and others were added in subsequent years. Of these schools there are now existing St Paul's, St Peter's (Westminster), Christ's Hospital (Blue Coat School), Merchant Taylors' School, Chateaufort, St Martin's School, and the City of London School.

St Paul's School, St Paul's Churchyard, was re-established in 1512 by Dean Colet, for the free education of one hundred and fifty-three poor children, and was endowed with lands whose original annual value was £128, 4s. 7½d., but which now yield nearly £3000 yearly. This board of governors consists of thirteen members chosen by the Mercers' Company and nine nominated by the universities. Vacancies on the foundation are filled up by competition, and the school fee for the scholars is £20. The course of study, which formerly was chiefly classical, is now specially designed to prepare for the various examinations. The site of the school will soon be changed to West Kensington, where grounds to the extent of 16 acres have been purchased.

St Peter's School, Westminster, re-endowed by Queen Elizabeth in 1565, provides for 40 quarter's scholars on the foundation, and the school is also situated by about 180 day pupils. Besides six minor exhibitions tunable at school, there are eight exhibitions to Oxford or Cambridge. The management of the school is regulated by the Public Schools' Act of 1868. The school, which is in the Dean's Yard, was formerly the dormitory of the monks of the abbey.

Christ's Hospital (Blue Coat School), Newgate Street, founded by Edward VI. in 1548 on the site of the monastery of Gyffryth, has an annual income of over £16,000, and the number of children on the foundation is about 1180, including 440 at the preparatory school at Heston, of whom 99 are girls. The school is under the management of a board of governors, of which any one may be admitted on payment of a donation of £500. The education is chiefly classical, but few boys are annually sent to the universities. The boys still retain their ancient dress, as well as several peculiar privileges.

Merchant Taylors' School, which was formerly situated in Suffolk Lane, but in 1578 removed to the Chancery, was founded by the Merchant Taylors' Company in 1541, and provides for the education of 500 boys annually on payment of 12 guineas in the lower school, and 15 guineas in the upper. The site of the present building was purchased in about 1590, and the new school-house cost £20,000. The home of the preparatory schools in connexion with this, as well as the chapel of the date 1512, the master's lodge, and the great chamber, the tower of which is a very fine specimen of Elizabethan work.

Chateaufort, formerly a Carthusian monastery and afterwards the seat of the Howards, was purchased by Sir Thomas Sutton, and in 1611 endowed as a school. On the foundation 85 pensioners are maintained at Chateaufort, and 60 scholars at the school at Godalming, where it was removed in 1872.

The Mercers' Grammar School, Collegiate Hill, Dorgate, was originally attached to the hospital of St Thomas of Acon, which was sold in 1628 to the Mercers' Company on condition that they maintained the school. Of the 180 scholars 25 are free.

For the City of London School, founded by the City corporation in 1846, at Milk Street, Chancery, to supply education to sons of respectable persons, a new building is in course of erection on the Thames embankment. There are preparatory schools in connexion with University College and King's College.

Higher
education.

The University of London, Burlington Gardens, instituted in 1826, and removed in 1869 to its present building in the Italian Renaissance style, is a rare examining body for conferring degrees. University College, Gower Street, founded in 1828 on undemocratical principles, has the reputation in connection with the examinations—including engineering and the fine arts—that are taught in universities, with the exception of theology, and is attended by over 1500 students. The buildings, the chief feature of which is the Caianthian portico at the main entrance surmounted by a dome, were enlarged by a wing in 1881, and contain a large library, and the Plaxman gallery, with original models by Plaxman. King's College, erected by Smirke in 1832, and forming the east wing of Somerset House, provides similar instruction to University College, but with the addition of theology, and in connection with the Church of England. At Gresham College, founded in 1572 by Sir Thomas Gresham, and removed to its present building in Beaufort Street in 1843, lectures are given on law, divinity, the sciences, music, and medicine. The lectures of the London Society for the Extension of University Teaching have been instrumental in stimulating to some degree general interest in literary and scientific subjects, and in 1861 were attended by 3080 persons. The legal lectures in

connexion with the Inns of Court are noticed in the article INNS or COURT, vol. xii. p. 65.

SCIENCE.—The great medical schools owe their fame and success in part to the attraction which London presents to eminent physicians and schools of surgeons, and to the existence of extensive medical and surgical hospitals, which afford unequalled opportunities for the study of diseases. In addition to the university of London, the Royal College of Physicians, founded by Langens, physician to Henry VII. and Henry VIII., is an examining body for diplomas in medicine, and the Royal College of Surgeons, which originated in the lively company of Barber-Surgeons, formed by the incorporation of the surgeons with the barbers in 1640, has similar authority in regard to the practice of surgery. The College of Physicians, originally located in the private house of Langens on Knight-Rider Street, and afterwards in a building designed by Wren in Warwick Lane, removed to its present site in Trafalgar Square in 1826, where a Greco-Ionian structure was erected from the designs of Smirke at a cost of £30,000. The College of Surgeons, Langens's Inn Fields, erected 1835-37 from the designs of Barry at a cost of £40,000, contains the Hunterian Museum, purchased by parliament in 1789 (see HUNTER, vol. xii. p. 389), an extensive library, and a lecture theatre. Until the time of John Hunter the medical and surgical education obtainable in London was of a very unsystematic character, chiefly of a private nature, the provision made for dissection being often of the meagreest kind, while the lectures on anatomy and surgery were both undervalued in a course of six weeks. Hunter's lectures, not delivered in 1774, was a very influential effort in the development of the medical and surgical schools connected with the hospitals, but their most rapid progress has been during the present century. A full description both of these hospitals and of the hospitals for special diseases will be found in THOMAS DE GRANT, vol. viii. p. 238, and the article HOSPITAL, vol. xii. p. 301, &c. Other among the chief scientific schools of London may be mentioned scientific the Royal School of Mines, Jernyn Street; the Normal School of Science, South Kensington; the Royal Veterinary College, Camden Town; the Royal Naval College, Greenwich; the Royal Naval School, New Cross; the Royal Military Academy, Woolwich; and the School of Naval Engineering at the Crystal Palace. The Guilds of London Institute, for the advancement of technical education, has lately founded colleges at Finsbury and South Kensington. The foundation stone of the South Kensington Institute was laid in 1862, and the building will be opened in 1884, the cost being £75,000, making a total with the Fine Arts College of £100,000, in addition to £25,000 for fittings. The amount contributed by the Library Companies to the endowment is £25,000.

The most influential of the scientific societies is the Royal Society, Scientific incorporated by Charles II. in 1663. Originally located near Sotheby's, Gresham College, Canoe Court, it was removed in 1760 to Somerset House, and since 1857 it has occupied rooms in the Strand, Piccadilly. In 1864 old Burlington House, built by Richard Boyle, earl of Burlington, was purchased by the Government for £140,000, and in 1872 a new building in the Renaissance style was erected for the various societies formerly accommodated in Somerset House, viz., the Chemical Society, the Geological Society (founded 1807, incorporated 1850), the Society of Antiquaries (1707, 1761), the Royal Astronomical Society (1820, 1831), and the Linnean Society (1788, 1802). The Royal Geographical Society (1830, 1856), occupying a commodious building in Savile Row, has within the last forty years taken a leading part in promoting geographical discovery. The Royal Asiatic Society (1823) is in Albemarle Street. The Royal Institution of Great Britain, in the same street, established in 1799 chiefly for the promotion of research in connexion with the experimental sciences, possesses a large library, a mineralogical museum, a chemical and a physical laboratory, and a foundation for a course of lectures. The Society of Arts, in Pall Mall, Adelphi, established in 1754 and incorporated in 1817, for the encouragement of arts, manufactures, and commerce, offers rewards for new inventions and discoveries, and grants certificates and prizes for proficiency in commercial knowledge, the industrial arts, musical theory, and domestic economy. Among other scientific societies the principal are the Society of Meteorology, the Anthropological, the Entomological, the Numismatic, the Zoological, the Botanical, the Horticultural, the Institute of Civil Engineers, and the Royal Institute of British Architects. The Zoological Society, instituted in 1826, rented in 1868 a portion of Regent's Park, where their established gardens which now contain some of the finest collections of live specimens in the world. The gardens of the Botanical Society, which occupy 18 acres of Regent's Park, are not of a strictly scientific character, being used chiefly for promenade, and flower shows, and are to be distinguished from the Government gardens at Kew, where the arboretum and New (p. 1). The Horticultural Society, founded in 1864, possesses large fruit and flower gardens at Chiswick, and in 1861 entered upon a lease of 23 acres of ground, formerly occupied by the Exhibition of 1861, which they laid out at a cost of £50,000, and where they now hold their flower shows and fairs.

Of museums, London possesses two on a scale of unexampled

Scientific museums. The British Museum and the South Kensington Museum. The geological collections of the British Museum are still at Bloomsbury, but the departments of geology, mineralogy, and botany were removed in 1881 to a new building in Cromwell Road, South Kensington, called the British Museum of Natural History. The British Museum at Bloomsbury, and the South Kensington Museum, which are usually connected with art than science, are noticed under the section Art. The Museum of Practical Geology, Jernyn Street, occupies a building in the Italian Palazzo style, erected in 1850 by Pannethouse at a cost of £30,000. It was founded in 1835 in connexion with the geological survey of the United Kingdom, and is especially rich in collections illustrative of the application of the minerals and metals to the useful arts. In the Patent Office Museum at South Kensington there are many of the original examples of the greatest mechanical inventions of modern times; and the United Service Museum, Whitehall, possesses relics and models illustrating both of the art of war and of the great naval and military achievements of England.

The drama. DRAMA.—According to Fitzstephen, London, "instead of shovels upon theatres and comical pastimes," possessed in his time "holy plays and representations of miracles"; and Sawmarche tells us in 1591 a play by the parish clerk continued three days together, and "that another in the year 1409 lasted eight days, and was "of matter from the creation of the world." In the 16th century the secular began to supersede the sacred drama, the progress in London under Elizabeth and James I. will be touched on below (pp. 246 *et seq.*) after the Restoration, the "king's servants" who had previously occupied the Globe and Blackfriars played first at the Bull Bull, then in Vere Street, Clare Market, and in 1638 removed to the Theatre Royal in Drury Lane. For De Witt's company, known as the "dike over York's," the Lincoln's Inn theatre was built on an improved plan in 1603, and there for the first time women actors were introduced. The two companies received each special patents in the same year. Before 1672, when Drury Lane theatre was burned, De Witt had removed to a new house built by Wren in Dorset Gardens, and had taken of by a by-product as "like Nero's voice slurring all with gold"; and, as the new Drury Lane was far less magnificent in its arrangements, it generally had the worst of the costly competition in which they engaged until the union of the patents in 1682. In 1686 a licence was granted to a new theatre in Lincoln's Inn Fields, and in 1706 Haymarket theatre was opened, chiefly for Italian opera. The Dorset Gardens theatre was demolished in 1709. In 1738 the Lincoln's Inn theatre was removed to Covent Garden. The Act of 1737, which forbade the granting of new licences, gave to the patent houses a monopoly of the legitimate drama till 1743; but in the earlier houses, such as "The Little Haymarket" (erected in 1720), the Goodman's Fields theatre (1737), Sadler's Wells (1764), the Lyceum (1766), the Adelphi (about 1800), the Princess's (1880), the Strand (1831), and St James's (built by Ibrahim, 1836), the law was evaded by the performance of miscellaneous entertainments. The most striking feature in the dramatic entertainments of London is their variety; the old dramatic traditions of England, so closely associated with Drury Lane and Covent Garden, now exercise their influence rather in Germany than in London. London at present possesses about thirty theatres, and the plays of the older dramatists are revived only occasionally, chiefly at Drury Lane, the Lyceum, and the Princess's. Melodrama and the domestic drama were large support, but many theatres rely chiefly on comedy, farce, or operaboules.

Musical perform- ances. MUSIC.—In 1573 the celebrated career of English opens in London was first maintained by the performance at Dorset Garden of *Pygmalion*, followed by *The Tropic* and a little later *The Prophet* and *King Arthur*. For some time after the opening of the Haymarket theatre, Italian opera were varied by performances of English opera and the spoken drama, but the increasing success of the new entertainment soon led to its exclusive establishment. Since 1847 Italian opera has also been established at Covent Garden. English opera has lately been successfully revived by Carl Rosa, and Italian opera is also threatened with formidable rivalry by the performance on a scale of unexampled grandeur of Wagner's operas in Germany, chiefly at Drury Lane, the Lyceum, and the Princess's. The Academy of Ancient Concerts, established in 1710, had the honour in 1732 of introducing to the world that special development of Handel's genius, the oratorio, which still excites a wider and deeper interest in England than any other form of musical composition. The Ancient Concert Society did not find a worthy successor in its special sphere till the establishment of the Sacred Harmonic Society in 1821, which has since its annual series of performances, formerly in Exeter Hall and lately in St James's Hall, has organized great triennial festivals at the Crystal Palace. Oratorio performances on a larger scale than those of the Sacred Harmonic are now given at the Royal Albert Hall, but the nature of the building renders them less successful artistically. The Philharmonic Society has since its commencement in 1813 held a leading position in the performance of

great instrumental works, which previous to this had been commenced at subscription concerts conducted by private enterprises, but the orchestral performances at the Crystal Palace are of equal excellence, and of late years the Richter and Halle concertos have excited a larger amount of general interest. The Monday and Saturday popular concerts for chamber music have been the usual means of introducing to London audiences instrumental performances of European fame. By the formation of Henry Leslie's choir in 1855, the standard of refinement and taste in unaccompanied patting has been improved throughout England, and besides reviving general interest in glass and madrigals, it has been the successful means of giving currency to the "modern pat song." The choir, after the suspension of its performances since 1880, was revived in 1882; and there are also in London several local choirs which have attained nearly equal perfection in similar performances. The Bach Society devotes itself to the study and performance of the unaccompanied music of Bach and the other composers. The earliest renderings of the great classical compositions are associated rooms with the Hanover Square concerts, converted into a club house some years ago, and in a less degree with Wall's rooms, built in 1705, which are now used almost solely for balls and public meetings. The only concert-room in London of a convenient size for important performances is St James's Hall, Regent Street and Piccadilly, for since the purchase of Exeter Hall, associated with the "May meetings," by the Young Men's Christian Association, its use is prohibited even to the Sacred Harmonic Society, and the Royal Albert Hall is much too large for the proper reduction of the choir effects of choral, orchestral, or solo performance. This elliptical building in the Italian Renaissance style, erected from the designs of Captain Fowler, was completed in 1871 at a cost of £200,000, and has accommodation for an audience of about 9000 and an orchestra of 1000. The Crystal and Alexandra Palaces, though they present the additional attractions of fine grounds, of scientific and art exhibitions, and of various forms of outdoor amusement, have their claims to suit in a great measure on their theatrical and musical performances, and, besides the large central halls for promenades, possess various concert-rooms. The Crystal Palace, Sydenham, which has a total surface of 1008 feet, and a width at the nave of 313 feet, and at the central transepts of 384 feet, was designed by Sir Joseph Paxton, and constructed in 1854, chiefly of iron and glass, out of the materials of the Exhibition building of 1851, at a cost of £1,500,000, including the adornment of the grounds, 200 acres in extent. The Crystal Palace, Sydenham, which has a total surface of 1008 acres, was completed in 1876, after having been burned down in 1873. It is built of brick in the form of a parallel loggia, covering about 7½ acres, and consists of a central hall 384 feet by 184, two courts on each side 220 feet in length, and a concert-room and theatre detached from the main building. The Crystal Palace and other entertainments are given at the Royal Aquarium, Westminster, which was opened in 1875 at a cost of about £200,000.

In London there are probably a larger number of eminent pro-Musical fessors of the various branches of music than in any other city of modern the world, but almost no provision for public musical instruction has been made by the State. The Royal Academy of Music, instituted in 1822, and incorporated by royal charter in 1850, receives from Government only an annual grant of £500, and, though attended by over 400 students, chiefly professional, is hampered in its organization and plans by deficiency in funds. The Guildhall School of Music, in which instruction may be given at an earlier stage, was established by the corporation of the City in 1870, and is now attended by 1200 students. The National Training School at South Kensington, for which endowments for only five years were provided, is now discontinued, a proposal having been made to supersede it by a Royal College under the presidency of the Prince of Wales, and with endowments to be devoted to afford free education to 50 pupils, as well as maintenance and education to 50 others. The Tomte Sol-Fa College, Planter, was incorporated in 1876 for the special purpose of training teachers of music for the elementary schools of the country, that method of instruction in music being now used in the majority of schools where systematic musical instruction is given.

PAINTING, SCULPTURE, AND THE APPLIED ARTS.—The most Art influential and the oldest institution in London connected with galleries. painting and sculpture is the Royal Academy of Fine Arts, founded in 1768, which, besides its annual exhibition of art in its new buildings in Burlington Gardens, Burlington House, erected in 1868-69, in the Italian Renaissance style from the designs of Smirke, has also organized classes for art instruction. The Society of Painters in Water-Colours, established in 1804, the Society of British Artists, founded in 1822 and incorporated in 1847, and the Institute of Painters in Water-Colours, which hold each an annual exhibition. The National Gallery of Paintings originated in the purchase by parliament in 1824 of the collection of J. J. Anguier for £37,000. The present Crocker building by William in Trafalgar Square (1822-88) was enlarged in 1860 and 1880, and in 1878 a new wing was added by Barry at a

cost of over £80,000. The collection has received many additions both by purchase and bequest, and besides many noble examples of the old masters, contains some of the finest pictures of the English school, including the magnificent Turner collection. The National Portrait Gallery, the nucleus of which was formed in 1858, was removed to Exhibition Road, South Kensington, in 1870. In the Grosvenor Gallery, New Bond Street, erected by Sir Costa Lindsay in 1877, there are annual exhibitions of works of art, and occasionally other special exhibitions. Several of the mansions of the nobility contain art galleries, which are open to the public on certain conditions. The most famous of these are perhaps the Grosvenor Gallery in the residence of the duke of Westminster, and the Hughenden Gallery in the residence of the earl of Kilmorest.

British Museum. The British Museum, Bloomsbury, originated in the purchase by Museum Government in 1753 of the collection and library of Sir Hans Sloane, and occupies the site of Montagu House. For the reception of the Egyptian antiquities presented by George I. (1801) of the Torwally mummies (1805), and of the Elgin marbles (1816), a new wing was added to the building in 1823, but after the presentation of the king's library by George IV. in the same year, it was resolved gradually to reconstruct the whole building, the first portion being finished in 1828, and the work (except the new reading-room) completed in 1857. The exterior of the building is plain, with the exception of the massive Ionic portico at the principal entrance. The contents of the museum are divided into departments, which are under the charge of a keeper and one or more assistant keepers. The departments still at Bloomsbury are those of Printed Books, Manuscripts, Oriental MSS., Zoology, Oriental Antiquities, Greek and Roman Antiquities, Gems and Medals, British and Medieval Antiquities and Numismatics, and Prints and Drawings. The collection both as a whole and in several departments—especially Greek and Roman Antiquities and Engravings—is unequalled in the world, and in all the departments a very high degree of completeness has been attained. For the library and reading-room, see **LIBRARIES**, p. 515.

South Kensington Museum. which is under the direction of the Committee of Council on Education, was originated by the late Prince Consort in 1852. The present building, to which the collection was removed from Marlborough House in 1857, is erected of red brick and terra cotta in the Italian Renaissance style, and, though still in process of construction and development, includes a fine range of apartments, the interior consisting of courts and corridors of graceful proportions, and decorated with various designs. It contains a collection of works of ornamental art, both ancient and modern, as applied to manufacture, a national gallery of British art, in addition to the Foster and Dyce collections, and a fine collection of water colour paintings, an extensive art library, a collection of sculpture chiefly of the Renaissance period, reproductions of ancient sculpture and paintings, and collections of animal products employed in the arts of substance used for food, and of materials used for building and construction. Some of the rooms are occupied chiefly by articles on loan. In connexion with the institution there is a National Art Training School, as well as a School of Science and a School of Cookery. The Natural Green Museum, a branch of South Kensington Museum, opened in 1872, besides a permanent food collection, and a collection of animal products, is occupied with various collections on loan. The India Museum, which was removed in 1880 from the India Office to a building in Exhibition Road, South Kensington, and placed under the care of the South Kensington Museum directors, contains a magnificent collection of every variety of Indian art and manufacture. The Science Museum, Lincoln's Inn Fields, bequeathed to the nation by Sir John Soane in 1837, contains an architectural library, various models of famous ancient buildings, antique sculptures, gems, vases, and bronzes, and several fine paintings. The Royal Architectural Museum, Westminster, founded in 1847, is intended especially to advance the art of architecture by examples of the works of various nations and times, and by courses of lectures, and drawing and modelling classes.

CLUBS.—See **CLUBS**, vol. vi. p. 41.

Churches. **ECCLIASTICAL BUILDINGS.**—FitzStephen states that in his time there were in London and its suburbs thirteen larger conventual churches besides one hundred and twenty-six lesser parochial ones. Stow gives a list of churches existing when he wrote, mentioning those which he knew to be suppressed or united to others. He gives the names of 125 churches, including St Paul's and Westminster Abbey; 89 of these were destroyed by the great fire, and only 45 were rebuilt.

Paul's. St Paul's cathedral occupies the site of a church founded in 610 by Ethelbert. After the destruction of the church by fire in 1087, a new edifice in the Norman style was

commenced, which was forty years in building, and according to William of Malmesbury "could contain the utmost conceivable multitude of worshippers." In 1240 a new Pointed Gothic choir was added, and the erection of a lofty tower began. The work of renovation and adornment was continued until 1316, when the cathedral was declared complete. Its dimensions as given by Stow were as follows:—height of steeple 520 feet; total length of church 720 feet; breadth 130; and height of the body of the church 160 feet. In 1561 the spire was struck by lightning, and the roof of the church partly destroyed by the fire that ensued. From this time it remained in a dilapidated condition until the reign of Charles I., and the work of restoration under the direction of Inigo Jones, who added to the west front a Corinthian portico, had not been completed when the building was destroyed by the great fire of 1686. St Paul's cross, which stood at the north-east corner of the cathedral, was rebuilt by Bishop Kemp in the 15th century, but was removed in 1643, its place being now occupied by a fountain. At the cross great religious disputations were held and papal bulls promulgated, and in its pulpit sermons were preached before the court. The present St Paul's, erected in 1675-97 from the designs of Sir Christopher Wren at a cost of £747,954, is built in the form of a Latin cross, the length being 600 feet, the breadth at the transepts 250 feet, and of the choir and nave 125 feet. The dome, which separates the two transepts and the nave and choir, rises to a height of 385 feet, or of 404 feet to the top of the cross by which it is surmounted, the height of the interior dome being 225 feet. The principal front to the west consists of a double portico of Corinthian pillars flanked by campanile towers 120 feet in height. The transepts are bounded by semicircular rows of Corinthian pillars. St Paul's is remarkable chiefly for its massive simplicity and beautiful proportions. The interior is imposing from its vastness, but the designs of Wren for its decoration were never carried out. Some of the monuments of the old building are preserved in the crypt, where are also the tombs of Sir Joshua Reynolds, Dr Samuel Johnson, J. M. W. Turner, Lord Nelson, the duke of Wellington, and other distinguished men, especially admirals and generals.

Westminster Abbey, as the coronation church of the West-sovereigns of England from the time of Harold, and on account of its proximity to the seat of English government, has acquired a fame and importance which in a certain sense outvie those of St Paul's. It occupies the site of a chapel built by Sæbert, in honour of St Peter, on a slightly elevated spot rising from the marshy ground bordering the Thames. A church of greater pretensions was erected by King Edward about 860; but, this church being partly demolished by the Danes, Edward the Confessor founded within the precincts of his palace an abbey and church in the Norman style, which was completed in 1065, and of which there now only remain the pyx house to the south of the abbey, the substructure of the dormitory, and the south side of the cloisters. The rebuilding of the church was commenced by Henry III. in 1220, who erected the choir and transepts, and also a lady chapel, which was removed to make way for the chapel of Henry VII. The building was practically completed by Edward I., but the greater part of the nave in the Transition style, and various other improvements, were added down to the time of Henry VIII., including the west end of the nave, the deanery, portions of the cloisters, and the Jerusalem chamber; while the two towers at the west end were erected by Wren, who had no proper appreciation of Gothic. The length of the church, including Henry VII.'s chapel, is 531 feet, or, excluding it, 416 feet, the breadth of the transepts 208 feet, the height of the church 102 feet, and of the towers 225 feet. The choir, where the coronation of

English sovereigns takes place, is a fine specimen of Early English, with decorations added in the 14th century, and contains among other tombs those of Sisebert, king of the East Saxons, Anne of Cleves, and Edmund Crouchback, earl of Leicester. The north transept is occupied principally with monuments of warriors and statesmen, and in the south transept the "poet's corner" contains memorials of most of the great English writers from Chaucer to Thackeray and Dickens. The nave, with its clustered columns, its beautiful triforium, and its lofty and finely proportioned roof, is the most impressive portion of the interior. The monuments in its north and south aisles are of a very miscellaneous character, and commemorate musicians, men of science, travellers, patriots, and adventurers. The monuments in the chapels of St Benedict, St Edmund, St Nicholas, St Paul, St Erasmus, St John the Baptist, and the Abbot Islip are chiefly to ecclesiastics and members of the nobility. Henry VII's chapel, which is remarkable for the fretted vault work of the roof, with its magical fan tracery, contains besides the monument of Henry VII the tombs of many English sovereigns and their children, and also of various other personages of historic fame. In the chapel of Edward the Confessor are the shrine of Edward the Confessor in Purbeck marble, the altar tomb of Edward I., the coronation chairs of the English sovereigns, and the stone of Scone, the old coronation seat of the Scottish kings. In the chapter-house (1250) the meetings of the Commons took place before they were transferred to St Stephen's Chapel; and in the Jerusalem chamber (1376-86), where Edward V. is said to have been born and Henry IV. was brought to die, the sittings of the lower house of convocation of the province of Canterbury are now held.

Among the conventual churches existing in the time of Fitzstephen, there were destroyed by the fire three, those of St Thomas of Acon, St John the Baptist, and St Martin-le-Grand, founded of time in 700. Of the other churches there still remain the choir, part of the nave, and portions of the transepts of the old church of St Bartholomew the Great, dating from the foundation of the monastery by Rahew, minister to Henry I., included in the present church, restored 1835-59, which also contains the tomb of its founder, a pontical part of the old church of St Catherine Cree, which was the conventual church of St Asaph's proxy of the Holy Trinity, founded in 1168, but since rebuilt by Inigo Jones, the vaults and some of the old monuments of the old church of St James's, Clerkenwell, built in connexion with the Benedictine nunnery 1100, and replaced by the present structure 1788-92; the east wall and Norman crypt of the building which in the 16th century replaced the old church of the priory of St John's of Jerusalem, Clerkenwell, founded in 1100, and of which the south gate in the Perpendicular style, built in 1504, still remains, and the Temple church, raised in the reign of Henry III. Of the ancient church of St Saviour's, Southwark, belonging to the priory of St Mary Overy, a few seemingly Anglo-Saxon portions were incorporated in the building in the Early English style erected in the 13th century, which has been much designed by reconstructions and additions, although the beautiful choir, lady chapel, and transepts remain almost entire. The church of St Katherine's Hospital was removed in 1825 to make way for St Katherine's docks.

Of the other churches which escaped the fire the principal are the Chapel Royal, Surrey, rebuilt by Henry VII. on the site of Sorely Palace in connexion with the hospital of St John the Baptist, from 1584 till 1717 used as the parish church of St Mary-le-Strand, considered a chapel royal in 1778, and restored in 1805 by Sanluis after partial destruction by fire. All Hallows, Barking, founded in connexion with the Benedictine convent of Beaulieu, Essex, some time before Richard I., chiefly Perpendicular, and containing several brasses; St Andrew's Undershaft (1680-32), in the Perpendicular style, with a turret tower, and containing among other tombs that of Sir the chancellor; St Giles's, Cripplegate, founded 1090, rebuilt in the Gothic style after destruction by fire in 1646 (with the exception of the fine tower, added in 1660), where Cromwell was married, and Milton and Fox the martyrologist were buried; St Helene's, Backergate Street, founded in connexion with a priory of nuns (1218), chiefly in the Third Pointed style, and containing many brasses and monuments of city dignitaries; St Margaret's, Westminster, founded by Edward the Confessor,

re-erected by Edward I., and frequently restored, containing a window originally executed by Gouda for Waltham Abbey, and possessing a large number of monuments to eminent persons. St Olave's, Fleet Street, in the Gothic style, belonging to the 15th century, but much dilapidated by restoration, containing a large number of brasses and monuments, the small church of Trinity, in the Minster, formerly connected with a convent founded by Blanche, wife of Edmund Plantagenet, second son of Henry III., containing in a state of complete preservation the lead of the duke of Suffolk, father of Lady Jane Grey.

That the only important external feature of Wren's churches is Wren's the tower or steeple is a peculiarity to be explained by the fact, that the most of his style consisted, more in beauty of general outline than in elaboration of details, that from the amount of money placed at his disposal he was generally compelled to concentrate his chief attention on a special part of the building, and that on account of the crowding of surrounding buildings the steeple was often the only part of the church that could be made effective. His interiors, however, are finely proportioned. Among his more important churches are St Dunstons, Fleet Street, which possesses one of his finest steeples, and contains the statue of Richelieu the novelist; St Dunstons in the East, of which the only specimen by Wren now remaining in the city, resting on octagonal columns with a mural crown copied from St Nicholas, Newcastle; St James's, Piccadilly, only remarkable for its elaborate interior and a white marble font by Gibbons; St Lawrence, Jewry, St Mary-le-Bow, containing the Norman crypt of the old building, which was the first church in the city built on a new site, the nave, and adorned with one of the finest of Wren's steeples, in which are the proverbial "Bow Bells"; St Michael's, Cornhill, with Perpendicular tower mutated from that of Magdalen College, Oxford; St Mary, Aldermanbury, rebuilt by Wren on the Gothic model of the old church; St Stephen's, Walbrook, with an interior similar to St Paul's; St Andrew's, Cornhill Street, in a wall of which the famous "London Stone" is found, and St Clement Dances, in which Dr Samuel Johnson was accustomed to worship.

Of the churches of the period succeeding that of Wren, the most later notable are St George's, Hanover Square (1721), St James's, with churches, St George's, and St Andrew's, both in the city, and the church made at Marlborough, St Giles's in the field (1731), by Pitt-Croft, with tapering spire, and containing the graves of Livian in the sculptor and Andrew Marvel; St Martin-in-the-Fields (1726), by Gibbs, with a fine Corinthian portico, behind which the spire is a severely placed; St Mary-le-Strand (1717), by Gibbs, occupying the site of the old chapel; St Mary-le-Bow (1731), by Hardwick, in the Classic style, containing an altar-piece executed by Wren to the old church; St Paul's (1722), with a steeple in imitation of the Temple of the Winds, and a very elaborate interior copied from the Erechtemus at Athens; St Paul's, Covent Garden, originally designed by Inigo Jones, and restored after the fire in 1795. The more modern churches are wholly in the Gothic style.

Of the religious buildings connected with the monastic domain. Other towers and nationalities, few possess exceptional interest either for churches or architectural character. St George's, Cathedral, and Southwark (1848), designed by Pugin, is said to be the largest chapel. Roman Catholic buildings erected in England since the Reformation; and Ely Chapel, Holborn, the only remaining relic of the palace of the bishops of Ely, has lately been purchased and restored by the Roman Catholics. Among the chapels belonging to the Protestant dissenters the best known are perhaps All Saints on the Tottenham, the City Temple, and Christ Church, Nottingham. The Dutch Church in Amsterdam was presented by Edward VI. to the Dutch residents in London in 1550; the nave is in the Decorated style of the 13th century.

Lambeth Palace, situated near one of the old lakes or Lunden-Lambeth places of the Thames, came into the possession of the archbishops of Canterbury in 1197. The oldest portion of its present building, including the chapel in the Early English style, was erected by Archbishop Boniface (1544-70), but the Lollards' Tower, in which the Lollards were tortured and the civil of Essex was imprisoned, was built in 1484, and the great hall with an elaborate timber roof in 1558. The inhabited portion was erected 1828-48 from the designs of Blois. The handsome double staircase is the oldest part of which dates from the 14th century, contains the tombs of several archbishops, as does also the palace chapel. The library is noticed in LITERATURE, p. 516.

ROYAL PALACES AND GOVERNMENT BUILDINGS.—Stow mentions that in his time there was a large building called the Old Wardrobe in the Old Jewry, very ancient, but of which all that he knew was that it had been allotted to by Henry VI. as his principal palace in the Old Jewry. The palace of Westminster existed at least as early as the Palace reign of Canute, but the building spoken of by Fitzstephen of Westminster as an "incomparable structure furnished with a breastwork

and a bastion" is supposed to have been founded by Edward the Confessor, who built what was afterwards known as the Painted Chamber, and also the apartment afterwards used by the House of Lords. The palace was probably enlarged by William the Conqueror, and William Rufus built the great hall in 1087. The palace suffered severely from fire in 1563 and 1599, and after the great fire of 1513 it was no longer used as a royal residence, and was allowed for a time to fall into decay, with the exception of the great hall. Subsequently it was fitted up and made use of for the meetings of parliament until 1835, when again the whole, with the exception of the great hall, fell a prey to the flames. The apartment in which the House of Commons met was the beautiful St Stephen's chapel, originally built by Stephen. Westminster Hall, which is 290 feet long, 68 feet wide, and 90 feet in height, with a carved timber roof remarkable for its beauty and the ingenuity of its construction, is used as the vestibule of the law courts and the Houses of Parliament. According to Stow the "princes" after the destruction of Westminster Palace "lodged in other places about the city, as at Bernard's castle (which was destroyed in the great fire), at Drudwell, and Whitehall, sometimes called York Place, and sometime at St James's." It was at Drudwell, which occupies the site of an old Norman tower, and was for a long time the occasional residence of the kings of England, that Henry VIII., who, according to Stow, built there "a stately and beautiful house of new," was staying, on account of the destruction of Westminster Palace, when the interview took place in 1528 between him and his nobles, commemorated in the third act of Shakespeare's *Henry VIII.* After the fall of Wolsey, York House, which from 1546 had been the residence of the archbishops of York, came into the possession of the crown, and obtained the name of Whitehall. The palace was almost reconstructed by Henry VIII., who made it his principal residence, and employed Holbein in its decoration; but a new banqueting hall, erected by James I. in place of the old one burned down in 1615, was the only portion of the building which escaped the destruction caused by fire in 1691 and 1697. This hall, converted into a royal chapel by George I., is a fine specimen of Palladian architecture, and its ceiling is adorned with allegorical paintings by Rubens. Through the banqueting hall Charles I. passed on his way to execution beneath its windows, and Cromwell breathed his last within an apartment of the palace.

St James's Palace, which after the destruction of Whitehall continued to be the principal royal residence until it was nearly all destroyed by fire in 1809, with the exception of the old gateway, the chapel adjoining, and the presence chamber, was built by Henry VIII. for a country residence instead of Kennington, on the site of an old hospital for lepers founded in the 12th century.

Buckingham Palace, the town residence of Queen Victoria, occupies the site of Buckingham House, purchased by George III. in 1761. The present building in the Classic style was erected 1825-35 by Nash, a west wing with a dull facade 460 feet in length, facing St James's Park, being added in 1848, and a large ball-room in 1856. The picture gallery contains a specially fine collection of pictures by the great Dutch masters.

Kennington Palace, a favourite residence of several English sovereigns, is noticed under KENSINGTON. Marlborough House, built by the first duke of Marlborough in 1710 from the designs of Wren, came into the possession of the crown in 1817, and has been occupied by the Prince of Wales since 1863.

The Tower of London, on the east of the city on the left bank of the Thames, called by Fitzstephen the Palatine Tower, was, according to tradition, originally built by

Julius Caesar, but the nucleus of the present building was begun in 1078 by William the Conqueror, who erected the part now known as the White Tower to take the place of a portion of the walls and towers of the city which had been washed away by the Thames. This tower was completed in 1088 by William Rufus, who also began the St Thomas Tower and the Traitor's Gate. Additions were made at various periods, especially by Henry III., who used it frequently as a residence; and it now occupies an area of 13 acres surrounded by a moat, constructed in 1190, enclosing a double line of fortifications, behind which is a ring of buildings consisting of various towers, and the barracks and military stores, while in the centre is the massive quadrangular White Tower, with Norman arches and windows, and adorned with a turret at each corner. The St John's chapel in this tower is one of the finest and most complete specimens of Norman architecture in England. The Tower of London has an extensive collection of armour, and is the repository for the regalia of England. The execution of the long list of important political prisoners confined in the Tower took place on the neighbouring Tower Hill, and most of them were buried in the chapel of St Peter ad Vincula.

The new palace of Westminster (1840-67), built at a cost of about £800,000 from the designs of Barry, for the Houses of Parliament, stands on the site of the old palace destroyed by fire in 1855, is a vast and magnificent building in the Tudor-Gothic style, covering altogether an area of about 8 acres. Towards the river it presents a very richly adorned and electric facade. At the north-east corner is the clock-tower, 320 feet in height, resembling the clock-tower at Bruges; above the dome over the central hall a spire rises to the height of 400 feet, and the Victoria tower, 310 feet, surmounts the royal entrance at its south-west corner. The central hall, which is entered by St Stephen's Porch and St Stephen's Hall, built above St Stephen's Crypt, a portion of the old building, separates the House of Peers, which, along with the royal rooms, occupies the western portion of the building, from the House of Commons, to which the eastern portion is assigned.

The Government offices, situated in Whitehall and Downing Street, form several miscellaneous groups erected at different times and in very various styles of architecture. The Treasury offices, Whitehall (1787), containing the official residence of the premier, the Education Office, the Privy Council Office, and the Board of Trade, was improved in 1847 by the construction of a new facade designed by Barry. The Horse Guards, the headquarters of the commander-in-chief, an insignificant building with a central clock-turret, was erected in 1788 on the site of a guard-house built in 1681 for the security of Whitehall. The Admiralty, a plain structure with a Grecian facade, was erected in 1726. The new Public Offices, a fine range of buildings in the Italian style, erected from the designs of Sir Gilbert Scott at a cost of over £500,000, contain the Home, Foreign, Colonial, and Indian Offices, and various other departments. Somerset House, Strand (1778-86), a large quadrangular structure, the finest facade of which is that towards the river, occupies the site of a palace founded by Protector Somerset in 1547. It contains the Exchange and Audit Offices, the inland Revenue Office, the Office of the Registrar-General, the Admiralty, Register, and the Prerogative Will Office, removed from Doctor's Commons in 1874. The other Government offices at present occupy unpretentious buildings in various streets, chiefly in the neighbourhood of Whitehall and Westminster. Her Majesty's College (College of Arms), the authority in regard to pedigrees and armorial bearings, is located in Queen Victoria Street, in a building re-erected in 1668 from the designs of Wren. The General Post-Office, St Martin's-le-Grand, City (1826-39), designed by Smirke in the Grecian style, and occupying the site of St Martin's church and abbey, will probably soon be removed farther westwards. The General Telegraph Office, opposite the Post-Office, was erected 1870-73 at a cost of £450,000. The new Record Office in the Tudor style (1881-86) is situated in Fetter Lane.

The law courts, which are described in the article ENGLAND, vol. Law, viii. p. 261, and were accommodated in Lincoln's Inn and in courts, buildings adjoining Westminster Hall, where they were first established in 1254, will soon be all removed to the new Law Courts in the Strand, designed by Street, and estimated to cost about £500,000.

MEMORIALS AND STATUES.—The principal monuments are The Monument (1671-77), a fluted Doric column designed by Wren, and erected in commemoration of the great fire, at a cost of £18,700; the Nelson Column, Trafalgar Square, by Railton, erected in 1845 at a cost of £48,000, a copy in granite from the Temple of Mars Ultor,

Whitehall

St James's Palace

Buckingham Palace

The Tower

145 feet in height, crowned with a statue of Nelson by Barry, and having at its base four colossal bronze lions modelled by Sir Edwin Landseer; the Duke of York Column, Carlton House Terrace (1833), an Ionic pillar 124 feet, designed by Wyatt, surmounted by a bronze statue by Westminster; Westminster Column, erected to the memory of the old pupils of Westminster school who died in the Russian and Indian wars of 1854-59; the Guards Memorial, Waterloo Place, erected in honour of the foot guards who died in the Crimea, the Albert Memorial, Hyde Park, a highly decorated Gothic structure adorned with numerous niches and statues, erected from the designs of Sir Gilbert Scott at a cost of £190,000; Cleopatra's Needle, presented to the Government by Melomet Ali in 1819, brought from Alexandria in 1878, and erected on the Thames embankment on a pedestal of grey granite. Temple Bar, erected by Sir Christopher Wren (1670-72), was removed in 1877, but its site is at present occupied by an erection surmounted by a griffin.

Statues. The following is a list of the principal public statues:—

Name.	Site.	Sculptor.
Achilles	Hyde Park.	Westmacott.
Anna, Queen	St Paul's Churchyard.	Kneller.
Bateman, Earl of	Parliament Square	Westmacott.
Beckford, John, Duke of	Curzon Place	Kneller.
Burgoyne	Waterloo Place	Kneller.
Canning, George	New Palace Yard.	Westmacott.
Charles I.	White Horse	Le Sueur.
Charles II.	Chichester Hospital	Kneller.
Clyde, Lord	Waterloo Place	Kneller.
Cobden	Exmouth Road	W. C. Wyse.
Cumberland, Duke of	Greenwich Square	Kneller.
Derby, Earl of	Parliament Square	Westmacott.
Fox, Charles James	Broomfield Square	Kneller.
Franklin, Sir John.	Waterloo Place	Kneller.
George III.	Somerset House	Kneller.
Do	Cockspur Street	M. C. Wyse.
George IV.	Traveller Square	Kneller.
Harold	Traveller Square	Kneller.
Herbert, Lord	Pal Mall	Kneller.
Hill, Rowland	Whitehall	Kneller.
James II.	Whitehall	Kneller.
Jessner	Kensington Gardens	Kneller.
Kent, Duke of	Whitehall	Kneller.
Mill, J. S.	Victoria Embankment	Kneller.
Napier, Sir Charles	Traveller Square	Kneller.
Newton, Sir J.	Victoria Embankment	Kneller.
Pulford, Lord	Palace Yard	Kneller.
Philips, George	Royal Exchange	Kneller.
Port, Sir Robert	Cheapside	Kneller.
Pitt, William	Haymarket Square	Kneller.
Porter, General	Colston Viaduct	Kneller.
Richard I.	Old Palace Yard	Kneller.
Ross, Sir H.	Cholcon	Kneller.
Victoria	Royal Exchange	Kneller.
Wallington, Duke of	Green Park Arch.	Kneller.
Do	Royal Exchange	Kneller.
Do	Royal Exchange	Kneller.
William III.	St James's Square	Kneller.
William IV.	King William Street	Kneller.

HISTORY.

(C. F. H.)

BRITAIN AND ROMAN (to 449 A.D.)—Bishop Stillingfleet, writing in the London, stated that after the fullest inquiry he was enabled "to believe it of a Roman foundation, and no older than the time of Claudius" (*Origines Brit.*, 1665, p. 48); and several antiquaries and historians hold the same opinion. Although Geoffrey of Monmouth's vision of a great British city of Troynovant, founded by Brut, a descendant of Eneas, must be relegated to the limbo of myths, we need not anxiously dispute the existence of a British London. There can be little doubt that the name of London has a Celtic origin, and therefore there is probably a grain of truth in Geoffrey's fanciful description. The place was probably very small, but it must have been chosen for its commanding position on the banks of a fine river, and there may be some truth in the assertion that one Belinus formed a port or haven on the site of the present Dillinggate, although it does not follow that "he also made a gate of wonderful structure," or "ever it built a prodigiously large tower" (*Historia*, lib. i. cap. x.). What a British town was like we learn from Julius Cæsar, who tells us that it "was nothing more than a thick wood, fortified with a ditch and rampart, to serve as a place of retreat against the incursions of their enemies" (*De Bello Gallico*, v. 21). We may therefore imagine a clearing out of the great forest of Middlesex, extending probably from the site of St. Paul's Cathedral to that of the Bank of England, with the dwellings of the Britons spread about the higher ground looking down upon the Thames. The late Mr. Thomas Lewis believed that London had attained its prosperity before the

Romans came, and held that it was probably the capital of Cassivellaunus, which was taken and sacked by Julius Cæsar. Not satisfied with affirming the existence of a British London, he went further, and indicated its extent. On the hill situated between the river Fleet on the west and the Wallington on the east was seated the British town. The western gate was Ludgate and the eastern Dowgate, and much of Mr. Lewis's argument rests on the fact that these two names are of British origin (*Archæologia*, vol. xi. p. 48). The origin of London will probably always remain a subject of dispute, for want of decisive facts. A recent fact is suggested by any remains of an earlier date than the Roman occupation have been discovered, but, on the other hand, London could scarcely have come to be the important commercial centre described by Tacitus if it had only been founded a few years previously, and after the conquest of Claudius. Now then can be no doubt that the Britons made considerable progress during the period between Julius and Claudius, and it seems upon the whole highly probable that London as a British settlement may have come into existence then. There is some reason to believe that there were two settlements, one on the north and the other on the south bank of the Thames. If so they would be within the territories of distinct and possibly hostile tribes. There might be a ferry, and even, as we shall mention presently, a bridge of some description towards the close of the period, but this point will come before us again.

The Roman occupation of Britain extended over a period equal to that which has elapsed since Henry VIII. reigned. During those centuries (43-409 A.D.) there was ample time for cities to grow up from small beginnings, to overflow their borders, and to be more than once rebuilt. The earliest Roman London must have been a comparatively small place, but it probably contained a military fort intended to cover the passage of the river. The mouth of the Thames was then only a few miles from the large portions of what are now the counties of Kent and Essex being marshes overflowed with water. The original investigations of Sir Christopher Wren led him to take this view, and he expressed the opinion that "the whole country between Cumberwell Field and the hills of Essex might have been a great tract or mure of the sea, and much wider near the mouth of the Thames, which fills a large plain of sand at low water, through which the river found its way. This mighty broad sand (now good meadow) was restrained by large banks still remaining, and inducing the river into its channel, a great void, of which no history gives account, as the Britons were too rude to attempt it, and the Romans too much bound with continual wars, he concluding therefore it was Roman work" (Wren's *Antiquities*, p. 585). The opinion that these embankments are Roman work is the one generally held, but so greatly does opinion vary on all these points that some have supposed that they were not built until the reign of Henry VI. Neither Strabo nor the older Pliny allude to any such attempt; they wrote on Britain, and the name does not occur in literature until used by Tacitus. That author distinctly says that London had not in 61 A.D. been dignified with the name of a colony (*Annal.*, xiv. 33). The Roman general Tullius Suetonius, after marching rapidly from Wales to put down a serious insurrection, found Londinium unfortified for a basis of operations, and therefore laid the place to the mercy of Boadicea, who entirely destroyed it and killed the inhabitants in large numbers. When Tacitus wrote, Verulamium and Camulodunum possessed mure, but Londinium was not so distinguished. Subsequently, however, it became a place of importance. When the British power was finally destroyed, again grew into importance, and we find it holding an important position in the Itinerary of Antoninus, Londinium being either a starting-point or a terminus in nearly half the routes described in the portions devoted to Britain. Ptolemy mentions Londinium, but places it on the south side of the river; this may merely be a mistake on Ptolemy's part, but it seems probable that it was referred more particularly to Southwark, which, as has been already pointed out, may have had a distinct origin from the Londinium of the north bank of the river. Londinium was plundered in the reign of Diocletian and Maximian by the army of the usurper

¹ General Pitt Rivers (then Colonel James Pitt) discovered in 1857 certain piles in excavations near London Wall and Southwark River, probably the remains of a bridge, which he made the subject of a paper read before the Antiquarian Society of London (*Journal*, vol. v. pp. 122-124). These piles averaged 6 to 8 inches square, others of a smaller size were 4 inches by 1 inch, and one or two were as much as a foot square. They were found in long rows above the virgin gravel, and with them were found the refuse of kitchen middens, broken pottery, &c. of the Roman period, but there was no superstructure. There is not much here upon which to found a theory, but nevertheless the fact is a valuable item of evidence in a very complicated question. If, as seems certain, these piles are remains of the London of the Romans, and General Rivers thinks they were built by the Britons rather than by the Romans, and General Rivers thinks it probable that they are the remains of the British capital of Cassivellaunus, situated in the marshes, and of necessity built on piles, it is not probable that the

² Sir George Aylmer holds that the embankment of the lower reaches of the Thames could not have been undertaken until after the construction of Old London Bridge, as when that was built the tide was so high that it was necessary to build a bridge of 120 arches, which was the case. It is evident that, when the tidal water covered half the area of the Thames for a distance of 30 miles, the river proper must have been considerably shallower than at present, and it is not probable that the quantity of water shot off by the embankments equalled from five-eighths to three-fourths of the present tidal volume (*Proc. Inst. Civ. Eng.*, vol. xix. p. 67).

³ Dr. Guess affirmed that the notion of a British town properly "preceded the Roman camp has no foundation to rest upon, and is inconsistent with all we know of the early geography of this part of Britain" (*Archæologia*, vol. xii. p. 180). And Mr. J. B. Green in his lately published work, *The Making of England*, expresses the same opinion (p. 101). This was not, however, Mr. Kemble's belief, for he held that it was difficult to believe that Cæsar found an unimportant place even in Cæsar's day (*Sketches of England*, vol. ii. p. 219).

Allectus, but before the Franks who chiefly forced this army could fly Constantius sailed up the Thames and disembarked under the walls of the city, thus taking them by surprise. Under Julian London was the headquarters of Lupinus in his campaign against the Scots and Picts, and in the reign of Valentinian, Ammianus tells us, Theodosius came to London from Boulogne to mature his plan for the restoration of the tranquillity of the province. It is on this occasion that Ammianus speaks twice of Londinium as an ancient town, to which the title of Augusta had been accorded. By the anonymous geographer of Ravenna it is called Londinium Augusta. As Theodosius is said to have left Britain in a sound and secure condition, with all the fortified places restored, it has been supposed that to him was due the wall of the later Londinium. According to old tradition, however, Constantine the Great walled the city at the request of his mother Helena, who was said to be a native of Britain. In spite of these various references we should know very little of Roman London if it had not been that a large number of excavations have been made in different parts of the city, which have disclosed a considerable amount of early history.¹ These go to prove that the early city occupied a somewhat small area, for it has been discovered that the site of the Royal Exchange was originally a gravel-pit, and had then become a dirty pond outside the walls used as a receptacle for refuse. Constantine also once existed in Chispaide, on the site of St. Paul's, close to Newgate, and various other places known to have been included in the later Roman London. As it was illegal in Roman times to bury within the walls, these places must at one time have been extra-mural. Among the large number of important sepulchres remain lately found by Mr. Taylor in Newgate Street were several *ossuaries*, or leaden vessels for the reception of the calcined bones of the dead. Little attention had been paid to these objects until Mr. Roach Smith specially alluded to them in an article on "Roman Sepulchral Remains discovered near the Minors, London" (*Collections Antiquæ*, vi. 45-62). Subsequently Mr. Smith wrote a very elaborate article on "Roman Leadern Coffins and Ossuaries" (*Ibid.*, vii. 170-201), in which he refers to the wealth of the British natives as one of the chief incentives to the conquest of the country by the Romans, and that the large quantities of the costly metal, lead, "manufactured with much skill and so profusely as to supply not only the inhabitants of the towns, but those of villages and villas, with one of the chief requisites of advanced civilization," proves the prosperity and even luxury of the province. When Sir Christopher Wren was directing excavations for his building of Bow Church he sunk about 18 feet into the ground, where he first came upon "a Roman causeway of rough stone, close and well-rammed, with Roman brick and rubbish at the bottom for a foundation, and all firmly cemented." In consequence of this discovery the great architect came to the conclusion, which was corroborated by other remains, that the causeway he had found continued for the whole length of the town, and formed the northern boundary—"the breadth then north and south was from the causeway now Champagne to the river Thames, the extent east and west from Tower Hill to Ludgate, and the principal middle street or Prætorian Way was Watling Street" (*Parvula*, p. 269).

Although it is generally agreed that this early Roman city was comparatively small, and in form an oblong square (a *Londinium quadratum*), its exact situation must be a matter of conjecture. The late Mr. Arthur Taylor marked out a district which should be bounded on the west by the Walkbrook, on the east by Billingsgate, and on the south by the elevation of the bank of the Thames, as the northern boundary to be a line drawn below Lombard Street and Cornhill. Cannon Street and East Cheap would pass straight through the centre of this enclosure, with the other streets north and south (*Archæologia*, xxxii. 101). In corroboration of his views, Mr. Taylor points to the fact that no funeral urns have been discovered in the district he has marked out. Mr. Roach Smith agrees generally with Mr. Taylor, but includes a rather larger area. He writes—"I should be inclined to place the northern wall somewhere along the course of Cornhill and Leadern-hall Street; the eastern in the direction of Billings Street and Mark Lane; the southern, in the line of Upper and Lower Thames Street; and the western, on the eastern side of Walkbrook. This suggested plan will give the form of an irregular square, in about the centre of each side of which may be placed the four main gates corresponding with Bridge Gate, Ludgate, Bishopsgate, and Aldgate" (*Ibid.*, *Journal of London*, p. 14). The late Mr. W. H. Black, like his predecessors, takes the Walkbrook as a boundary, but, instead of making it the western limit, he makes it the eastern boundary, and places his western line at Ludgate. Newgate Street and Chispaide form the main thoroughfare of his city (*Archæologia*, xi. 41). Although Mr. Black argues his case with ability, his view is open to two principal objections,—(1) it leaves the site of London Bridge outside the enclosure, and (2) cemeteries have been

discovered within the proposed limits. As to the date when the hints of this early London were lost sight of in the larger area of the better known Roman city, we have hardly sufficient data even to hazard a conjecture. There is reason to believe, as already stated, that the site of the Royal Exchange was outside the city until the early part of the 3d century, because coins of Vespasian, Domitian, and Severan have been found among the refuse of this gravel-pit. Mr. Roach Smith suggests, however, that as no coins of the period between Domitian and Severan were found it is just possible that the plated denarius of the latter emperor may not have been found in the pit itself, but in the vicinity of the house which was built over the pit in subsequent years. On the other hand, Sir William Tite, in describing the tessellated pavement found in 1854 on the site of the Excise Office (Bishopsgate Street), expresses the opinion that the finished character of the pavement points to a period of security and wealth, and fixes on the reign of Hadrian (117-138 A.D.) to which the silver coin found on the floor belongs, as the date of its foundation. Of course this is not conclusive, as the pavement might have belonged to a villa outside the walls, but Sir William Tite places it within them. When the line of the walls which continued until the great fire was first planned out it is impossible to say with any certainty. Some antiquaries hold the opinion that these walls were post-Roman, but this is not the view of Mr. Roach Smith, one of our greatest authorities. Mr. J. E. Prie, after describing "a bastion of London wall" discovered in Canonio Street, Bishopsgate, arrives at "the conclusion that these interesting relics are portions of a Roman sepulchral monument which, falling into decay, became as years rolled on, a suitable quarry for medieval builders, providing from its position on the spot convenient materials for the erection of a structure requiring such solidity and strength as would a bastion to the city wall." In describing the outline of the Roman city it is impossible to make ourselves intelligible unless we use names adopted subsequently. The line of the wall runs straight from the Tower to Aldgate, where it bends round somewhat to Newgate.

It is bordered on the east by the Minors and Houndsditch. One of the finest remaining portions of the old wall was hidden from view a few years ago when some large houses were pulled down. It is the line from Bishopsgate now eastward to St. Giles's churchyard, where it turned to the south, as far as Falcon Square, again westerly by Aldgate against Clime's Hospital towards Giltspur Street, then south by Ludgate, and then down to the Thames. Mr. Roach Smith points out that the enormous gate which guarded the city from the east, known as the *Æliæ* gate, was built in 1848 a portion of the old wall was exposed to view in Playhouse Yard, Blackfriars, when a Roman monument erected to a "speculator" of the second legion, named *Celms*, was discovered. On the same line further north Sir Christopher Wren, while building St. Martin's, Ludgate, found a similar sepulchral monument "in the valley of the prætorian camp" to the memory of *Virianus Marcianus*, a soldier of the second legion (*Parvula*, p. 268). In the year 1275 the old wall south of Ludgate was pulled down and a new one built to enclose a larger circuit further west for the benefit of the Black Friars. There appear to be strong reasons for believing that a wall ran along the south, and that the Romans did not consider the river sufficient protection. William Fitzstephen, a monk of the 12th century, who wrote the earliest description of London, mentions the walls and tower in the south, and Sir Christopher Wren also alludes to the colony being walled near the Thames (*Parvula*, p. 264). The line from Lower Thames Street to Temple Street has been retrieved from the river by embankments, and in certain parts of the line the embankment was formed by substantial walling, such being found at the foot of Fish Street Hill, at the end of Queen Street, and from Broken Wharf to Lambeth Hill (*Tithe*). The *Æliæ* gate, as previously found at the Excavation at the *Æliæ* Exchange, 1848, p. xxiv). Mr. Roach Smith writes—"It was from 8 to 10 feet thick, and about 8 deep, reckoning the top at 9 feet from the present street level, and composed of ragstone and flint, with alternate layers of red and yellow, plain and curved-edged tiles, cemented by mortar and laid as the whole of the wall, which could not be separated. For the foundation strong, oaken piles were used, upon which was laid a stratum of chalk and stones, and then a course of heavy sandstones from 2 to 4 feet long, by 2½ in width" (*Archæologia*, *Journal*, i. 114). The names of the gates give us no clue as to which of them was the chief gate. Mr. Roach Smith does not doubt that the chief traffic was carried through the city from Ludgate to Aldgate, although some antiquaries have supposed that Newgate was the chief gate on the west side, leading as it would to Holborn, where Roman remains have been discovered. Bishopsgate must have been the principal gate on the east. Mr. Roach Smith has suggested the outside Newgate there was an amphitheatre built into a hill on the rising ground near what was lately the Little Old Bailey. He had often noticed the precipitous descent from Green Arbor Lane opposite Newgate into Sconcel Lane and the level space by Fleet prison, and he presumed to have been an excavation in the side of the hill, and that a smaller town than Londinium possessed a theatre in Roman times (*Middle-*

¹ A chronological list of the tessellated pavements discovered in London between 1851 and 1864 is given in a paper of the late Sir William Tite (*Archæologia*, vol. xlviii. p. 464). It is impossible to say how much more remains hidden many feet below the modern streets.

see *Arch. Trans.*, i. 33). The name Newgate is significant of its recent erection, and it has been remarked that it stands alone among the gates as not being attached to a ward bearing the same name. It is mentioned in an ordinance of Edward I., where it is connected with Ludgate.

A question arises as to the arrangement of the area included within the walls, the course of which has already been traced. There is a strong preponderance of evidence against the belief that the present line of streets follows that of Roman London to any considerable extent. Sir William Tite gave reasons for believing that Bishopsgate Street was not a Roman thoroughfare (*Archæologia*, xxvii. 293), and the late excavations in Leslie's Mill Mr. Loftus Brock found remains of a building which he supposed to be a basilica, apparently crossing the present thoroughfare of Gracechurch Street. Sir William Tite agreed with Dr Skeyley's suggestion that on the site of the Mansion House (formerly Stocks market) stood the Roman forum, and he states that a line drawn from that spot as a centre would pass by the pavements found on the site of the Exchequer Office. Besides the forum, Dr Skeyley suggested the sites of seven other public buildings,—the *Ara Palatina*, guarding the south-eastern angle of the city, where the Tower now stands, the grove and temple of Diana on the site of St Paul's, an episcopal residence, &c. No traces of any of these buildings have been found, and they are therefore purely conjectural. As to the temple of Diana, Wren formed an opinion strongly adverse to the old tradition of its existence (*Panthecon*, p. 266). Although we know that the Christian church was established in Britain during the later period of Roman domination, there is no reason to believe, as Mr. Loftus Brock has done, that the Bishop of Exeter who is said to have attended a council on the Continent is a somewhat mythical character.

After the walls the most important points for consideration in relation to Roman London are (1) the existence of a bridge, and (2) the purposes of the London Stone.

1. Dion Cassius, who lived in the early part of the 3rd century (*Hist. Rom.*, lib. ix. c. 20), states that there was a bridge over the Thames at the time of the invasion of Claudius (43 A.D.), but he places it a little above the mouth of the river ("higher up"). The position is vague, but, as already stated, the mouth of the Thames in these early times considered as not far from where the London Bridge now stands. Sir George Aylly holds that this bridge was not far from the site of London Bridge (*Proceedings of Institute. Civil Engineers*, xlix. 120), but Dr Guest was not prepared to allow that the Britons were able to construct a bridge over a tidal river such as the Thames, and he is of opinion that the difference of level at high and low water of nearly 50 feet. He therefore suggested that the bridge was constructed over the marshy valley of the Lea, probably near Stratford. It needs some temerity to differ from so great an authority as the late Dr Guest, but it does strike one as rather surprising that, having accepted the fact of a bridge made by the Britons, he should deny that these Britons possessed a town or village in the place to which he supposes that Antius Plautius retired. It may be considered certain that there was no bridge over the Thames in the time of Julius Cæsar; for he would not have marched his troops all the way to Coway Stakes in search of a ford if he could have crossed by a bridge at London.

As the Welsh word for "bridge" is "pont," and this was taken directly from the Latin, the inference is almost conclusive that the Britons acquired their knowledge of bridges from the Romans. Looking at the stage of culture which the Britons had probably reached, it would be further a natural inference that there was no bridge anywhere in Britain before the Roman occupation, but, if Dion's statement is correct, it may be suggested as a possible explanation that the increased intercourse with Gaul during the hundred years that elapsed between Julius Cæsar's raids and Claudius Cæsar's invasion may have led to the construction of a bridge of some kind, some 300 yards wide, at this point, through the influence and under the guidance of Roman traders and engineers. If so, the word "pont" may have been borrowed by the Britons before the commencement of the Roman occupation. Much stronger are the reasons for believing that there was a bridge in Roman times. Remains of Roman villas are found in Southwark, which was evidently a Roman station, and it is therefore hardly seem likely that a bridge-building people such as the Romans would remain contented with a ferry. Mr. Roach Smith is a strong advocate for the bridge, and remarks, "It would naturally be erected somewhere in the direct line of road into Kent, which I cannot but think pointed towards the site of Old London Bridge, both from its central situation, from the general absence of the foundations of buildings on the approaches on the northern end, and from discoveries recently made in the Thames on the line of the old bridge" (*Archæologia*, xlix. 120). Mr. Smith has, however, still stronger arguments, which he states as follows:—"Throughout the entire line of the old bridge, the bed of the river was found to contain ancient wooden piles; and, when these piles, subsequently to the erection of the new bridge, were pulled up to deepen the channel of the river, many thousands of Roman coins, with a small

ance of broken Roman tiles and pottery, were discovered, and immediately beneath some of the central piles brass medallions of Aurelius, Faustina, and Commodus. All these remains are indicative of a bridge. The enormous quantities of Roman coins may be accounted for by consideration of the well-known practices of the Romans to mark these imperishable monuments subservient towards perpetuating the memory, not only of their conquests, but also of those public works which were the natural result of their successes in remote parts of the world. They may have been deposited either upon the building or repairs of the bridge, as well as upon the accession of a new emperor" (*Archæologia*, xlix. 120). The "London Stone" has very generally been supposed to be a "milliarum" or central point for measuring distances, but Sir Christopher Wren believed it was part of some more considerable monuments in the forum, and his reason for this belief was that "in the adjoining ground on the south side (upon digging for cellars after the great fire) were discovered some tessellated pavements and other extensive remains of Roman workmanship and building" (*Panthecon*, pp. 265, 266). King, in his *Monuments Antiquæ*, writes—"London Stone, preserved with such reverential care through so many ages, and now having its top encased within another stone in Cannon Street, was plainly deemed a record of the highest antiquity of the still more important kind; though we sit at present unacquainted with the original intent and purpose for which it was placed. It is lived at present close under the south wall of St Swithin's Church, but was formerly a little nearer the channel facing the same place, which seems to prove its having had some more ancient and powerful designation than that of having been a Roman military station, as it was ever used for that purpose afterwards. It was lived deep in the ground, and is mentioned so early as the time of Attilian, king of the West Saxons, without any particular reference to its having been considered as a Roman military stone." Hollnhead (who was followed by Shakespeare in *2 Henry IV.*, act 4. sc. 6) tells us that when Cæsar, in 43, landed, he was very near London, he first of all proceeded to London Stone, and having struck his sword upon it, said in reference to himself and in explanation of his own action, "Now is Mortimer lord of this city." Mr H. C. Coote, in a paper published in the *Trans. London and Middlesex Arch. Soc.* for 1876, points out that this act meant something to the mob who followed the rebel chief, and was not a words of foolish acting. Mr G. L. Gomme (*Primitive Folk-Loose*, pp. 156, 156) takes up the matter at this point, and places the tradition implied by Cæsar's significant action as belonging to times when the London Stone was, as other great stones were, the place where the suits of an open-air assembly assembled to gather together and discuss the affairs of the government of the city. Corroborative facts have been gathered from other parts of the country, and, although more evidence is required, such as we have is strongly in favour of the supposition that the London Stone is a prehistoric monument.

Saxon (449-1066).—At the beginning of the 5th century the Roman legions left Britain. From this period to the arrival of the Saxons there was a space of time when the Britons were left alone, and there is no reason to believe that London craved to be the important commercial town which it had grown to be. After the Saxon invasion we do not hear of the city being ravaged, and it possibly held its own under the various vicissitudes it had to pass through, although Dr Guest writes this "good reason may be given for the belief that even London itself for a while lay desolate and uninhabited" (*Archæologia*, xix. 219). About 449 or 450 the invaders first settled in Britain, and in 467 Hengist and Æsc fought against the Britons at Owerford, driving them out of Kent. The vanquished fled to London in great terror, and spent the winter of 467 there. The Saxons disliked walled towns, and in many instances they destroyed those which they conquered. "This was not done in London, and it is just possible that the Britons may have been able to purchase their freedom from destruction. We have, however, little or no data upon which we can form an opinion. Mr Kenble writes of towns generally that the Saxons neither cared to take possession of them nor took the trouble to destroy them. They enslaved the inhabitants or expelled them, as a necessary precaution and preliminary to their own peaceable possession" (*Saxons in England*, i. 295). The only question is whether London, being an exceptional city, had an exceptional fate. Along the banks of the Thames are several small havens whose mounds have remained to us, such as Rotherhithe, Lambeth (Lambeth), Chelmsford (Chelms), and it is not unlikely that the Saxons who would not settle in the city itself associated himself with these small open ports. Fleets were thus founded over a large space which otherwise might have remained unsettled. At what time the

1. If the London-burg here mentioned in the Saxon Chronicle is not London itself of the Thames (or Southwark), the fugitives must have crossed the river, and if it is in addition reason for believing that there was then a bridge. The same reason will apply to whether the fugitives crossed the river to Surrey in the year 881, as it is not likely that a ferry would suffice on these occasions. Moreover, a bridge is shortly after specially mentioned by the

Saxons got over their repugnance and settled in London we cannot say, but the city is described by Bede as being in 604 the metropolis of the East Saxons, and an emporium of many peoples who came to it by sea and land. The riches of Roman London are, as we have already seen, very numerous, but we know nothing of the inhabitants. There is little human interest in the history.

When we come to Saxon London this position is reversed. There are no remains worthy of notice, but there is abundance of life. London appears to have held a very exceptional position, and to have been somewhat like a German free city. The Londoner within his strong walls defied the invader, and the Danes frequently attempted to conquer the city in vain. Mr. Freeman does justice to the stout heart of the Londoner, and calls London during this period "the stronghold of English freedom." The Saxon Chronicle has little to tell of London between the 6th and 9th centuries. The great change accomplished by Augustine in converting the Jutes and the Saxons to Christianity, is recorded in a few short lines, and we are told that in the year 604 Augustine consecrated two bishops, Mellitus and Justus, and that Ethelbert, king of Kent, gave Mellitus a bishop's see at London, then a part of the kingdom of the East Saxons, whose king, Suibert, was a tributary of his uncle the king of Kent. What blessing of the cathedral with us may suppose to have existed in London during the Saxon period we cannot tell, but we may guess that it was destroyed by the heathen Saxons. Bede records that the church of St Paul was built by Ethelbert, and from that time to this a cathedral dedicated to St Paul has stood upon the hill looking down on Ludgate. Mellitus became archbishop of Canterbury, and was succeeded by the sea of London by Ceolun, who was succeeded by Wina. Then came Theodore, archbishop of Canterbury, better known as the sainted Erkenwald, whose shrine was one of the chief glories of old St Paul's. He died on April 30, 690, a day which was kept in memory in his cathedral by special service. We must now pass over nearly a century and a half to the time when the Danes were harassing the country after the death of Egbert. The chronicle records that in the year 830 there was a great slaughter at London, but he gives no particulars. In 851 the Danes plundered the city and made themselves masters of it. Simon Turner quotes a conveyance of a place in London dated 857, which gives a slight piece of local information (*Anglo-Saxons*, p. 575). The name of the place was Colmaningehagen, and it was situated not far from the West Gate. We cannot tell whether Ludgate was meant or some other gate which marked the extent of the liberties on the west. In 871 the Danes, rebuffed at London, made great battles against the Danes in the kingdom south of the Thames, and that the West Saxons made peace with them. In the next year the Danes went from Reading to London, and there took up their winter quarters. Then the Mercians made peace with them. In 886 Alfred overcame the Danes, rebuffed at London, to the northwest, repulsed, it will, remember, the city to Merca, and committed it to Ethelred, alderman of Mercia. Then, as the chronicler writes, "all the Angle race turned to him [Alfred] that were not in bondage of the Danish men." In 890 the Londoners came off victorious in their encounters with the Danes. The king obstructed the river so that the enemy could not bring up their ships, and they therefore starved. The Londoners broke up some, and brought the strongest, and best to London. In 912 Ethelred, the alderman of the Mercians, who had been placed in authority by Alfred, died, and Edward the Elder took possession of London and Oxford, "and all the land which then belonged to him." Again we find a break in the continuity of the history, and pass on to the year 958, when King Edgar gave Dunstan the bishopric of Worcester, and afterwards that of London. In 992 there was a great fever and mortality in London, and St Paul's was burnt. It was, however, founded again in the same year. In the reign of Ethelred III. the Danes were more successful in their operations against London, but the inhabitants resisted stoutly. Snorro the Icelandic tells us that the Danes fortified Southwark with ditch and rampart, which the English assailed in vain. In 982 London was burnt, and in 994 Olaf and Swen (the father of Canute) came with ninety-four ships to besiege it. They tried to set the city on fire, but the townsman did them more harm than they "ever wowed." The chronicler proudly adds that "the holy Mother of God on that day manifested her mercy to the townsmen, and delivered them from their foe." The Danes went from the town and ravaged the neighbourhood, so that in the end the king was but witan agreed to give the enemy thousand pounds to be relieved of the presence of the enemy. In the year 1000 the Danes frequently attacked London, but they had no success, and failed ill in their attempts. The Londoners withstood Swen in 1013, but in the end they submitted and gave him hostages. Three years after this, Ethelred died in London, and such of the witan as were left fled to the townsmen chose Edward Ironside for king, although the witan outside London had elected Canute. Canute's ships were then at Greenwich on their way to London, where they soon afterwards arrived. The Danes at once set to work to dig a great ditch by Southwark, and then dragged their ships through to the west side of the bridge. They were able after

thus to keep the inhabitants from either going in or out of the town. In spite of all this, after fighting obstinately both by land and by water, the Danes had to raise the siege of London, and take the ships to the river Orwell. After a glorious reign of seven months Edmund died in London, and Canute became master of England. The tribute which the townsmen of London gave to Canute, 500,000, was about one-seventh of the amount which was paid by all the rest of the English nation. This shows the growing importance of the town. From this time there appears to have been a permanent Danish settlement in London. There is but little more to be said of the history of Saxon London than that Edward the Confessor had his witan assembled there, and built and consecrated a Abbey of Westminster. During the latter part of the Saxon period Westminster (originally Thorney Island) had been growing into some importance. Tradition affirmed that on the site of Westminster Abbey a temple of Apollo once stood, which was destroyed by an earthquake in the reign of the emperor Antoninus Pius. Out of the ruins King Lucius founded a church, 170 A.D. Sir Christopher Wien imagined that the monks, finding that the Londoners pretended to a temple of Diana where St Paul's now stands, did not wish to be behind hand in antiquity (*Peregrinations*, p. 266). The fragment respecting King Lucius is of about equal authority. There is no real reason for believing that Suibert, king of the East Saxons, may have built, as Stow says he did, "a church to the honour of God and St Peter, on the west side of the city of London." His sons reigned into idleness, and left the church to the mercy of the Danes. In a charter of King Edgar, dated 961, the original boundary of the church is clearly defined. This charter is marked by Kemble as doubtful (*Codex Dipl.*, 413x), but, if not of the date given, it is believed by competent authorities to be of great antiquity. Edward the Confessor took a particular interest in Westminster, and occupied much time in superintending the restoration of the church there. On Christmas day (December 28) 1065 the monastery was consecrated, and on the following "twelfth mass eve" the king died, being buried on the next day in the new church. The abbey of Westminster's manor is fully described in Domesday, but there is no mention of a palace, so that it has been conjectured that the Confessor lived in the monastery itself. With regard to the buildings of London we are left in the dark. As several of the Saxon kings lived in the city, we must conclude that they possessed a palace of some kind, and around the other buildings would arise. A port such as London naturally drew foreigners from all parts, and various communities of these strangers are believed to have been settled here as early as the reign of Alfred. As regard to the government of the city it is generally supposed that many of its institutions are due to Alfred the Great, although Mr. Coote with great ingenuity traces them back to the ordinances of the Roman *mundiculiarii*. The famous domes of the city of London are believed to have been erected by the king after the conquest. The bishop and the reeve belonged to London. William the Conqueror's charter, which he granted soon after his accession, is addressed to William the bishop and Godfrey the portreeve. The office of portreeve had then been long established, although we know but little of its origin. It was usually an office of popular election, but the king often interfered in the appointment. Considerably more than a century had elapsed after this Conquest before the title of portreeve gave way to that of mayor, as the designation of the chief officer of the city of London.

NORMAN (1066-1154).—After the battle of Hastings certain of the defeated chiefs retired upon London and urged the men in power to resist the Norman, and set up Edgar Atheling as king, which, as the Saxon chronicler says, "was indeed his natural right." On hearing of this action William marched towards London, and was attacked by the Saxon party at Southwark, where they were repulsed by the Norman horse, but with such loss to the latter that William thought it imprudent to lay siege to the city at that time. The Londoners began now to see the hopelessness of their cause, and Archbishop Eldred, and Edgar, and Eadric Elwin and Morcar, and "the best men of London" repaired to Berkhamstead, where they submitted themselves and swore fealty to the conqueror. One of the earliest acts of the Conqueror was to organize the erection of a citadel which should overcome the citizens and give him the command of the city. Some writers have supposed that King Alfred erected a palace or castle on the site of the Tower, but without sufficient authority, and a writer in the *Quarterly Review* (2d. Middlesex, vol. cl. p. 48 note) says, "the Tower almost certainly stands on foundations which was not dry land before the Conquest." As the Tower was situated at the eastern limit of the city, so not far from the western extremity was built a strong fortification called Baynard's Castle after its founder Baynard, one of the followers of the Conqueror. In the second year of his reign William granted the remarkable charter written in Anglo-Saxon which still exists among the archives of the city of London. There are but four lines and a quarter, and the size of the slip of parchment is only 6 inches by 1 inch. It runs thus—"William the king greets William the bishop, Godfrey the portreeve, and all the burgesses within London, both French and English. And I grant them

they be all law-worth, as they were in Edward the king's days. And I will that each child be his father's heir after his father's days. And I will not suffer that any man do you wrong, God keep you." William Sugard, the bishop of London, was a Norman, and possibly had some influence with the king in obtaining this charter. A wonderful improvement in the appearance of the state of the country almost immediately followed the advent of the civilizing Norman. Within a few years the whole area of London must have been changed, and handsome buildings arose as if by magic in all parts of the city. Many Normans had settled in London during the reign of Edward the Confessor, but after the Conquest they swarmed in, and naturally became the dominant party. In August 1077 occurred a most extensive fire, such a one, says the Chronicle, as "never was before since London was founded." This constant burning of large portions of the city is a marked feature of its early history, and we must remember that, although stone buildings were rising on all sides, these were churches, monasteries, and other public edifices; the ordinary houses remained as before, small wooden structures. The White Tower, the famous keep of the Tower of London, was commenced by Gundulph, bishop of Rochester, about the year 1078. In 1083 the old cathedral of St Paul's was commenced on the site of the church which Eadbert is said to have founded in 610. But four years afterwards the chronicle tells us "the holy monastery of St Paul, the episcopal see of London, was burnt, and many other monasteries, and the greatest and fairest part of the whole city." In this same year (1087) William the Conqueror died. In 1096 a tremendous hurricane passed over London, and blew down six hundred houses and many churches. The Tower was injured, and a portion of the roof of the church of St Mary-le-Bow, Chancery, was carried off and fell some distance away, being forced into the ground as much as 20 feet, a proof of the badness of the thoroughfares as well as of the force of the wind. William Rufus inherited from his father a love for building, and in the year 1087 he exacted large sums of money from his subjects with the object of carrying on some of the unled takings he had in hand. These were the walling round of the Tower, the rebuilding of London Bridge, which had been almost destroyed by a flood, and the erection of the great work with which his name is most generally associated, Westminster Hall. In 1100 Rufus died, and Henry I. was crowned as his successor. This king granted to the citizens their first real charter, in which he promised to observe the laws of the Conqueror and to redress many special grievances; but he paid little attention to his engagements, and constantly violated the articles of his charter. In 1116 he died, and his son Matilda, the wife of Henry I., he tried unsuccessfully to obtain the support of the people of London. He published a charter confirming in general terms the one granted by Henry, and commanding that the good laws of Edward the Confessor should be observed. The citizens, however, did not obtain their object, and the next year, in the year 1119 they paid Stephen one hundred marks of silver to enable them to choose their own sheriff. In this reign the all-powerfulness of the Londoners is brought very prominently forward. Stephen became by the shifting fortunes of war a prisoner, and the empress Matilda sought, if she had had the wisdom to favour the enemies, who soon afterwards replaced Stephen upon the throne. She, however, made them her enemies by delirring on the office of justiciary of London and the sheriffdom to her partisan Geoffrey, earl of Essex, and attempting to reduce the citizens to the enslaved condition of the rest of the country. This made her influential enemies, who soon afterwards replaced Stephen upon the throne. The Norman era closes with the death of Stephen, 1154.

We have already alluded to the great number of ecclesiastical foundations which marked the Norman period, and will here note some of the chief of these, to show how completely the new buildings must have changed the whole appearance of London, and raised it from a mean congregation of houses to the rank of a city having features of considerable architectural merit. The college of St Martin-le-Grand within Aldersgate was founded in the year 1058, and its rights were confirmed by the Conqueror in the second year of his reign. He gave to the whole appearance more land, and was added to their privileges. A monastery of the Benedictine order, dedicated to St Leonard, near Bromley, was founded in the reign of William the Conqueror by William, bishop of London, for a priory and nine nuns, and in Stephen's reign Sir William Mortmetcher founded an abbey of the same order at Langton, which was subsequently known as West Ham Priory. In 1083 a convent of nuns was dedicated to St Saviour was founded at Bermondsey by Alvin Ould, a wealthy citizen, and seven years afterwards some Cistercian monks came from France and settled in the new convent, of which one of them was chosen the first prior. In 1094 William Rufus added the manor of Bermondsey to the other possessions of this fortunate monastery, which became very powerful, and was frequently used as a royal residence. At Clerkenwell two religious houses were established in the year 1100, viz., the Knights Hospitallers of St John of Jerusalem and the priory of St Mary for nuns of the Benedictine order. It was said that the number of monasteries built in the reign of Henry I. was so great that almost all the labourers became

bricklayers and carpenters, and there was some discontent in consequence. Matilda or Mand, the wife of Henry I., was much interested in the foundation of those religious houses. She established the priory of Holy Trinity, called Christ Church, which was situated to the north of Aldgate, in 1108, and about 1110 two hospitals, one for lepers at St Giles-in-the-Fields, and the other for cripples at Chigwell. The priory of St Bartholomew was founded a few years earlier, and the Benedictine nunnery of St John the Baptist at Halliwell near Shoreditch soon afterwards. The Knights Templars made their first habitation in the neighbourhood of London in 1118, and did not remove from Holborn to Fleet Street until nearly seventy years afterwards. The royal hospital of St Katherine's at the Tower was originally founded by Matilda, wife of King Stephen, and the famous St Stephen's chapel at Westminster owes its origin to the king himself. It was, however, rebuilt by Edward I. It will be seen from the above list that a large proportion of those buildings were outside the walls, and this shows how extensive the outskirts of the city had become in Norman times. No doubt many of these religious persons sought out somewhat quiet neighbourhoods, but almost each of them would naturally grow up villages formed by those who were chiefly dependent upon the monks and nuns.

PLANTAGENET (1154-1485).—Henry II. appears to have been to a certain extent prejudiced against the citizens of London on account of their attitude towards his mother, and he treated them with some severity. On several occasions he exacted large sums from the city, which, although they were economically styled *taxes*, cannot be considered as free gifts. The severity applied to be very necessary, and was attended with good results. The streets were in a most dangerous condition at night, and bands of a hundred and more would sally forth to rob the houses of the wealthy. In 1175 some of these men were taken prisoners, and one of them was found to be a citizen of good credit and considerable wealth named "John the Old." He offered the king five hundred marks for his life, but Henry was inflexible, and after the man had been hanged the city became more quiet. In 1176 the rebuilding of London Bridge with stone was commenced by Peter of Colchester. This was the bridge which after much subsequent repair was pulled down early in the present century, and consisted of twenty stone arches and a drawbridge. There was a gateway at each end and a chapel or crypt in the centre, dedicated to St Thomas of Canterbury, in which Peter of Colchester the architect was buried in 1205. In 1184 the Knights Templars removed from Holborn to the Temple, and in the year 1190 and in the following year the beautiful Temple church was built. All this activity of building proves that the citizens were wealthy and their city handsome. This is corroborated by the interesting work of Fitzstephen, the monk of Canterbury, which was written at this time. Fitzstephen has left us the first picture of London, and a very vivid one it is. He speaks of its wealth, commerce, grandeur, and magnificence—"of the multitude of the climate, the beauty of the gardens, the sweet, clear, and salubrious springs, the flowing streams, and the pleasant clack of the water-mills. Even the vast forest of Middlesex, with its densely wooded thickets, its covets of game, stags, fallow deer, boars, and wild bulls is pressed into the description to give a contrast which shall enhance the prosperous beauty of the city itself. Fitzstephen's account of the sports of the people is particularly interesting. He tells how, when the great marsh that washed the walls of the city on the north (Moonhede) was frozen over, the young men went out to slide and skate and sport on the ice. Skating had, in fact, been dug up of late years in this district. This sport was allowed to fall into disuse, and was not again prevalent until it was introduced from Holland after the Restoration. In the first year of Richard I. the court of aldermen ordained that for the future houses should not be built of wood, but that they should have an outside wall of stone raised 16 feet from the ground, and be covered with slate or baked tile. This ordinance must have fallen into desuetude, for the houses continued largely to be built of wood. We learn that most of the houses were plastered and whitewashed. One of the earliest objections which the Londoners made to the use of sea-coal was that the smoke from it darkened the walls of their buildings. The first mayor of London was Henry Fitz Alwin, who was elected in 1159, and held the office until 1212.

London had to pay heavily towards Richard's ransom; and, when the king made his triumphal entry into London after his release from imprisonment, a German mobster in said to have remarked that had the emperor known of the wealth of England he would have insisted on a larger sum. The Londoners were the more glad to welcome Richard back in that the hand of the regency, Longchamps, bishop of Ely, was very unpopular from the encroachments he made upon the city with his works at the Tower. The first charter by which the city claims the jurisdiction and conservancy of the river

It was first admitted to the chief magistracy as bailiff, and there appears to have been a considerable variety in the titles which were given to the office. The *Liber Albus* that the chief officer was sometimes called "Justice" and "Judge-bailiff."

Thames was granted by Richard I. John granted several charters to the city, and it was expressly stipulated in Magna Charta that the city of London should have all its ancient privileges and free customs. The citizens opposed the king during the wars of the barons. In the year 1215 the barons having received intelligence secretly that they might enter London with ease through Aldgate, which was then in a very unwarlike state, removed their camp from Bedford to Ware, and shortly after marched into the city in the night-time. Having succeeded in their object, they determined that so important a gate should no longer remain in a defenceless condition. They therefore spoiled the religious houses and robbed the monastery colleges in order to have money wherewith to rebuild it. Much of the material was obtained from the destroyed houses of the unfortunate Jews, but the stone for the bulwarks was obtained from Caen, and the small bricks or tiles from Flanders. The church of St Mary Overy (now St Saviour's), Southwark, was begun in the year 1309, and in 1321 the foundation stone of the holy chapel at Westminster Abbey was laid by Henry III. We have alluded to the great change in the aspect of London and its surroundings made during the Norman period by the establishment of a large number of monasteries. A still more important change in the configuration of the interior of London was made in the 13th century, when the various orders of the friars established themselves there. The Bonaventuran monks preferred secluded sites; the Augustinians did not cultivate seclusion so strictly; but the friars chose the interior of towns by preference. The Black, Preaching, or Dominican Friars settled near Holborn, in what was afterwards Lincoln's Inn, in 1221, and removed to the ward of Castle Buryard in 1278, where the city wall was rebuilt to enlarge their boundaries. The district where the friary was built still retains its name. In 1234 John Iwyn or Ewan made over to the Grey Friars (or Franciscans) an estate situated in the ward of Farringdon Within and in the parish of St Nicholas in the Shambles, and on this site the first convent of the order was erected. The site is now occupied by the Blue Coat School. In 1341 the White Friars or Carmelites settled in a precinct or liberty between Fleet Street and the Strand which still retains their name. In 1563 the Austin Friars or Friars Eremites were founded in Broad Street ward, and the last of these houses to be established was that of the Grey or Carmelite Friars in 1598. By the establishment of these religious houses two thirds of the entire area of London was occupied by convents and hospitals. This is the most marked characteristic of Plantagenet London. We have no record of the date at which Temple Bar first marked out the extent of the liberties of the city, but the date of the establishment of the century Fleet Street was described as being in the suburbs. During the Norman period the road from the city to Westminster was quite open, but soon afterwards a commencement was made in building. The Savoy was built in 1245 by Peter, earl of Savoy and Richmond, uncle of Eleanor, wife of Henry III., and in the king's reign the Friars of the order of St Mary de Aroua are supposed to have established themselves near the site of Durham House (now the Adelphi). About the same time William Marshal, earl of Pembroke, founded and endowed a hospital and convent called St Mary Komersall at the village of Chiswick, so that in Henry III.'s reign there must have been several houses on the line of route to Westminster. Fitzstephen describes the latter place as follows:—"On the west also, higher up the bank of the river, the royal palace rears its head, an incomparable structure, furnished with a breastwork and bastions, situated in a populous suburb at a distance of two miles from the city." In the reign of Edward I. the king offended the king and the citizens were for a time deprived of their right of electing their chief magistrate. Gregory de Rokesley the mayor, the sheriffs, the aldermen, and other dignitaries of the city were summoned to appear on the 29th June 1285 before John de Kirkby, treasurer, and the other justifiers of the king in the Tower of London for the purpose of holding inquiries there. Now the mayor held that he was not bound to answer such a summons as this unless he had forty days' notice, so he resigned his mayoralty at Allhallows, Barking, and delivered the common seal of the city to Stephen Aysn and other aldermen, and then entered the Tower with the rest as an exile only. This action incensed the king greatly, and John de Kirkby was commanded to take over the mayoralty, a warrant being appointed by the royal authority. This arrangement continued until 1297, when Edward granted the prayer of the citizens, and allowed them again to elect a mayor. Royal wardens had filled the mayor's seat from 1046 to 1285, but the first charter of Edward in the following concession was made:—"Also that the liberties of the city of London shall not be taken into the hand of his lordship the king for any personal trespass or personal judgment of any officer of the said city; and that no warden shall in the same on such pretext be appointed." (*Charters of London*, edited by Riley, pp. 14, 15). In 1381 the first attempt was made to supply London with water artificially, and the great conduit in West Cheap (or Cheshide) was commenced. This led eastern, which was cisterned with stone, was supplied with water conveyed in leaden pipes from Tyburn. Soon afterwards a nobler building was erected in Cheshide. In 1390 the beloved Eleanor of Castile

died, and her husband erected stone crosses where her body had rested. Two of these crosses were in London, and there is some little difficulty in understanding why the two stations were so near each other. It has been suggested that the body really rested at St Paul's Cathedral. Cheshide Cross was erected by Michael of Cheshidebury, and cost £200, and Channing Cross, the most stupendous of the series, cost £450. It was commenced by Richard de Crundale, and completed after his death by Roger de Crundale. In this same year (1290) the Jews were expelled from England. The district in London in which they had lived since William the Conqueror's day came to be called the Old Jewry, but when the Jews returned to England after many centuries of exile most of them settled in the neighbourhood of Aldgate.

Smithfield is mentioned by Fitzstephen as a market for horses, and from this writer we obtain its correct etymology (the smooth field). As early as the reign of Henry III. it had become known as the place for executions. Close by a grove of elm trees that gave their name to the place Sir William Wallace was executed in the year 1305, and there also Mortimer experienced a similar fate five and twenty years afterwards. The history of Smithfield from that day has been a record of executions, jousts, and markets. In 1313 the celebrated order of the Knights Templar fell, and Edward II. gave their house in Fleet Street to Aymer de Valence, earl of Pembroke. At the earl's death the property passed to the Knights of St John of Jerusalem, who leased the Inner and Middle Temples to the students of the common law and the Outer Temple to Walter Stapleton, bishop of Exeter, and last treasurer. The Cheshidebury monks made on a piece of ground which had been used in 1849 as a burial-place for the thousands who died in that year of the plague. In 1371 Sir Walter Manny founded there a priory of Carthusian monks.

One of those pageants for which the streets of London were so famous took place in 1356 when Edward the Black Prince brought the French king John a prisoner from the battle of Poitiers. It is not necessary to do more than allude to this here, as the incident is a part of English history.

We have now arrived at the period of one of the greatest London-dances that ever lived. The life of Geoffrey Hamlyn, the man whose living interest around the several places with which he was associated. His father was a vintner in Thames Street, the garden of whose house was bounded by the Wall Brook. In 1374 Chaucer was appointed controller of the customs, and in the same year he went to live in the dwelling-house above the gate of Westminster. In 1380 he was appointed clerk of groves and waters in the Tower of London, and other places. In March 1390 we find him on the Thames bank repair commission, and in May of the same year he was employed in setting up scaffolds in Smithfield for Richard II. and his queen (Anne of Bohemia) to see the jousts at the place. His duties took him to the mews for the king's falcons at Cheshide Cross, and in 1390 he was robbed of some of the king's money on the high road at Westminster. We thus see that traces of the "morning star of English poetry" are to be found in all parts of London.

In 1381 another of the stirring incidents of English history occurred in London. The threatening usurpation of Wat Tyler was suppressed when the leader was killed by Sir William Walworth in Smithfield. Before that the rebels had done great damage to property in London and Southwark. About this time Henry was repulsed by Richard II. in 1387; the walls were carried up 2 feet higher, the windows were altered, and a new roof constructed. In 1411 the Guildhall was built, and the courts were removed from Aldermanbury.

During the troubles of the 15th century the authorities had seen the necessity of paying more attention to the security of the gates and walls of the city, and when Thomas Nevill, son of Thomas, Lord Fauconberg, made his attack upon London in 1471 he experienced a very spirited resistance. He first attempted to land from his ships in the city, but the Thames kids from Daynard's Castle to the Tower was so well fortified that he had to seek a quieter and less prepared position. He then set upon the several gates in succession, and was repulsed at all. On the 11th of May he made a desperate attack upon Aldgate, followed by 500 men. He won the bulwarks and some of his followers entered into the city, but the portcullis being let down there was cut off from the city, and the besieged fought their way against the rebels, who were soon forced to fly.

When Richard, duke of Gloucester, had his plans for seizing the crown, he obtained the countenance of the mayor, Sir Edmund Shute, whose brother Dr Shaw praised Richard at Paul's Cross. Croyly Hall, in Balphogate Street, then lately built, was made the lodging of the Protector. There he acted the accessible prince in the eyes of the people, for the last of the Plantagenets was another of the usurpers who found favour in the eyes of the masses of London. His day, however, was short, and with the battle of Bosworth ends Plantagenet London.

London continued to grow. In 1666 a conduit was constructed at Dowgate for the purpose of obtaining water from the Thames, and in 1589 Peter Moris, an ingenious Dutchman, brought his scheme for raising the Thames water high enough to supply the upper parts of the city under the notice of the lord mayor and aldermen, and in order to show its feasibility he threw a jet of water over the steeple of St. Magnus's Church (see p. 825). The maps show us much that remains somewhat the same as it was, but also much that has greatly altered. St. Giles's was literally a village in the fields. Popularly it was "the way to Bealinge," Oxford Street "the way to Uxbridge," Covent Garden an open field or garden, and Leicester Fields famous land. Moudfelds was a canal, and laid out in walks in Elizabeth's reign. At Spitalfields crowds used to congregate on Easter Monday and Tuesday to hear the Spital sermons preached from the pulpit cross. The ground was originally a Roman cemetery, and about the year 1676 bricks were largely made from the clayey earth, the mouldering of which is kept alive in the name of Brick Lane. Citizens went to Holborn and Bloomsbury for change of air, and houses were there prepared for the reception of children, invalids, and convalescents. In the north were sprinkled the outlying villages of Islington, Hoxton,

and Clerkenwell. The Strand was filled with noble mansions washed by the waters of the Thames, but the street, if street it could be called, was little used by pedestrians. Londons were frequented the river, which was then great highway. The banks were crowded with stairs for boats, and the watermen of that day answered to the charmen of a later date and the cabsmen of today. When Shakespeare and his companions went to see at the Globe Theatre they did not cross London Bridge, but took boat at Blackfriars Stairs, and were landed opposite at the Paris Garden Stairs on the Bankside. The Bankside was of old a favourite place for entertainments, but two only—the bull-baiting and the boat-racing—were in existence when Agassiz's map was first planned. On Norden's map, however, we find the gardens of Paris Garden, the boathouse, and the playhouse.

The settled character of the later years of Elizabeth's reign appears to have caused a considerable change in the habits of the people. Many of the chaf citizens followed the example of the courtiers, and built for themselves country residences in Middlesex, Essex, and Surrey, thus we learn from Norden that Alderman Roe lived at Mowell Hill, and we know that Sir Thomas Gresham built a fine house and planned a beautiful park at Osterley.

Norden's Map of Tudor London

STUART (1603-1714).—The Stuart period, from the accession of James I. to the death of Queen Anne, extends over little more than a century, and yet greater changes occurred during those years than at any previous period. The early years of Stuart London may be said to be closely linked with the last years of Elizabethan London, for the greatest men such as Raleigh, Shakespeare, and Ben Jonson lived on into James's reign. Much of the life of the time was then in the City, but the last years of Stuart London take us to the 18th century, when social life had permanently shifted to the west end. In the middle of the period occurred the civil wars and then the fire which changed the whole aspect of London. When James came to the throne the term suburbs had a bad name, as all those disreputable persons who could find no shelter in the city itself settled in these outlying districts. Then the line of the Strand was almost the only respectable outskirts. Stubbs denounced suburban gardens and garden houses in his *Anatomy of Abuse*, and another writer observed "how happy were men if they had no suburbs."

The preparations for the coronation of King James were inter-

rupted by a severe visitation of the plague, which killed off as many as 30,578 persons, and it was not till March 15, 1664, that the king, the queen, and Prince Henry passed triumphantly from the Tower to Westminster. The last mayor's show, which had been discontinued for some years, was revived by order of the king in 1609. The dissolved monastery of the Charterhouse, which had been bought and sold by the courtiers several times, was obtained from Thomas, earl of Suffolk, by Thomas Sutton for £15,000. The new hospital chapel and schoolhouse was commenced in 1611, and in the same year Sutton died. Somerset House was occupied by Anne of Denmark, and in 1616 James I. commanded it to be called Denmark House. In 1619 Inigo Jones commenced the Banqueting House at Whitehall, which was only part of a proposed vast palace, but which has remained to our time to be one of the chief ornaments of the town. The fatal vesper at Blackfriars threw a gloom over the year 1628. A large and mixed congregation of

¹ This map of London by Norden is dated 1698, as stated above. The same topographer published in his *Medicee* a map of Westminster as well as this one of the City of London.

Protestants and Roman Catholics had gathered together one Sunday evening at the house of Sir John, the French ambassador, to hear Father Drury (a converted Protestant) preach. As many as were able crowded into the room on the upper floor for that purpose, but those who could not get in were fain to remain on the floor below and listen to a preacher on the sacrament of penance. The floor both gave way, and a large number of persons were precipitated to the great depth and killed, both preachers being among the dead. With the death of James I. in 1625 the elder history of London may be said to have closed. During the reign of his successor the great change in the relative positions of London within and without the walls had commenced. Before going on to consider the third result of this change it will be well to refer to some features of the social life of London. Ben Jonson places one of the scenes of *Every Man in his Humour* in Moorfields, which at the time he wrote the play had lately been drained and laid out in walks. Beggars frequented the place, and travellers from the village of Horton, who crossed it in order to get into London and so with as much expedition as possible. Adjoining Moorfields were Finsbury Fields, a favourite practising ground for the archers. Mile End, a common on the Great Eastern Road, was long famous as a rendezvous for the troops. These places are frequently referred to by the old dramatists. Justice Shallow boasts of his doghouse at Mile End Green when he was Dogeant in Arthur's Show. Fleet Street was the show-place of London, in which were exhibited a constant succession of puppets, naked Indians, and strange fishes. The great meeting-place of Londoners in the day-time was the nave of old St Paul's. Crowds of merchants went to their hats on transacted business in the aisles, and used the font as a counter upon which to make their payments; lawyers received clients at their several pillars, and masterless serving-men waited to be engaged upon their own particular bench. Besides those who came on business there were galleed students in fashionable fustian, so that it was worth the student's while to stand behind a pillar and fill his table-books with notes. The middle or Mechtelmann aisle was the Paul's Walk, also called the Duke's Gallery from the erroneous supposition that the tomb of Sir Guy Beauchamp, earl of Warwick, was that of the "good" Humphrey, Duke of Gloucester. After the Restoration a fence was erected on the inside of the great north door to hinder a concourse of rude people, and when the cathedral was being rebuilt Sir Christopher Wren made a strict order against any profanation of the sacred building. Another of the favourite haunts of the people was the garden of Gny's Inn, where the choicest story-labourers in Chesapeake Road made the most of the elm trees which Bacon had planted, Pepps and his wife constantly walked. Mrs Pepps went on one occasion specially to observe the fashions of the ladies because she was then "making some clothes."

In those days of public conviviality, and for many years afterwards, the taverns of London held a very important place. The Bear's Head in Great Eastcheap was an inn of Shakespeare's own day, and the characters he introduces into his plays are really his own contemporaries. The "Mermaid" is sometimes described as in Broad Street, and at other times in Friday Street and also in Chesapeake. We are thus able to fix its exact position; for a little to the west of Bow Church is Broad Street, then come a block of houses, then Friday Street. It was in this block that the "Mermaid" was situated, and there appear to have been entrances from each street. What makes this fact still more certain is the circumstance that a haberdasher in Chesapeake Road was in Wood Street and Milk Street, two streets on the north side opposite Broad and Friday Streets, described himself as "over against the Mermaid tavern in Chesapeake." The Windmill tavern occupies a prominent position in the action of *Every Man in his Humour*. The Windmill stood at the corner of the old Jerry Leadenhall, and the Mitre close by the Mitre in the Strand. The Street. The Mitre in Fleet Street, so intimately associated with Dr Johnson, also existed at this time. It is mentioned in a comedy entitled *Love Alley* (1611), and Lilly the astrologer frequented it in 1640. At the Mermaid Ben Jonson may be supposed to have had such rivals as Shakespeare, Raleigh, Beaumont, Fletcher, Carey, Donne, Cotton, and Selden, but at the Devil in Fleet Street, where he started the Apollo Club, he was omnipotent. Herrick, in his well-known *Ode to Ben*, mentions several of the inns of the day.

Under James I. the theatre, which established itself so firmly in the latter years of Elizabeth, had increased its audience, and to the entertainments given at the many playhouses may be added the masques so expensively produced at court and at the inns of law. In 1615 "The Masque of Flowers" was presented by the members of Gny's Inn in the old Banqueting House in honour of the marriage of the Duke of York, and of Somerset, and the equally illustrious Lady Frances, daughter of the earl of Suffolk. The entertainment was prepared by Sir Francis Bacon at a cost of about £2000.

¹ Various changes in the names of the taverns are made in the folio edition of this play (1616) from the quarto (1611); thus the Mermaid of the quarto becomes the Windmill in the folio, and the Mitre of the quarto is the Star of the folio.

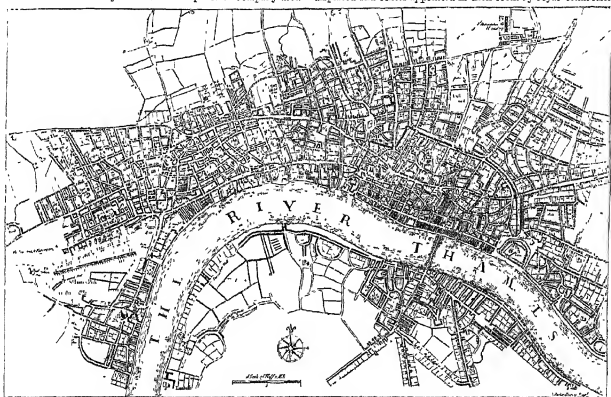

Charles I. and his counsellors were filled with the same fear of the increasing growth of London which showed itself in the prohibitory proclamations of his two predecessors. In 1630 a proclamation was issued in which "the election of any building upon a new foundation, within the limits of 3 miles from any of the theatres of the City of London, or suburbs of Westminster, was forbidden. The privy council in the following year put this question to the lord mayor—"What number of months are esteemed to be in the City of London and the liberty?"—the answer to be twelve, 320,268. These prohibitions were not allowed to remain a dead letter, and in 1635 Sir Pauline, a large landholder in Sussex, was fined by the Star Chamber in the sum of £2000 for living in London beyond the period prescribed in the proclamation of June 26th of that year. In April 1636 information was filed against Sir John Suckling the poet and others in the Court of Star Chamber for continuing to reside in London and Westminster. It was during this reign that the first great exodus of the wealthy and fashionable was made to the West End. The great system of piazzas of Covent Garden was formed from the designs of Inigo Jones about 1632. The neighbouring streets were shortly afterwards built, and the names of Henrietta, Charles, James, King, and York Streets were given after members of the royal family. Great Queen Street, Lincoln's Inn Fields, and the Strand were built about 1640, and named in honour of Henrietta Maria. Lincoln's Inn Fields had been planned some years before.

When the civil war broke out London took the side of the parliament, and an extensive system of fortification was at once projected to protect the town against the threatened attack of the royal army. A strong earthen rampart, flanked with bastions and redoubts, encircled the City, its liberties, Westminster, and Southwark, making an immense enclosure. Mount Street, Grosvenor Square, marks the spot of one of these fortifications called Oliver's Mount. In 1640 Cromwell allowed the Jews to return to England after a banishment of centuries, and those who settled in London mostly chose the neighbourhood of Aldgate as a place of residence. With the Restoration the separation of fashionable from dirty life became complete, and the West End grew into a formidable rival of the older London. In 1635 the game of ball mail was played in St James's Park, on the site of St James's Square and Pall Mall, but during the Commonwealth the park and the houses there were built round about. The square was planned out in 1663, and it soon became the most fashionable place in London. A mall was then prepared in St James's Park which still retains its name. About the same time the great houses in Piccadilly and Grosvenor Street, Berkeley Street, and Grosvenor Houses all appeared on the north side of that street about 1605.

London had been ravaged by plague on many former occasions, but the pestilence that commenced in December 1664 will ever live in history as "the Plague of London." On the 7th of June 1665 Samuel Pepys for the first time saw two or three houses marked with the red cross and the words "Lord, have mercy upon us," on the doors. The deaths daily increased, and business was stopped. Grass grew in the area of the Royal Exchange at Whitehall, and in the principal streets of the city. On the 4th of September, 1665, Pepys writes an interesting letter to Lady Carteret from Woolwich—"I have stayed in the city till about 7400 died in one week, and of them about 6000 of the plague, and little noise heard day or night but tolling of bells." . . . The plague was scarcely stayed before the whole city was in flame, a calamity of the first magnitude, but one which in the end raised much good, as the whole of the city was destroyed, and London has never since been visited by such an epidemic. On the 2d of September the fire broke out at one o'clock in the morning at a house in Pudding Lane. A violent east wind fanned the flames, which it raged with fury during the whole of Monday and great part of Tuesday. On Tuesday night the wind fell somewhat, and on Wednesday the fire slackened. On Thursday it was extinguished, but on the following day the flames again burst forth at the Temple. Some houses were at once blown up by gunpowder, and thus the fire was finally mastered. Many interesting details of the fire are given in Pepys's *Diary*. The distress of those who were made homeless by the calamity was great. The river swarmed with vessels filled with persons carrying away such of their goods as they were able to save. Some fled to the hills of Hampstead and Highgate, but Moorfields was the chief resort of the homeless Londoner. Some poor streets and two-story houses were seen in that swampy place. The people bore their troubles heroically, and Henry Oldenburgh, writing to the Hon. Robert Boyle on September 16, says, "the citizens, instead of complaining, discouraged almost of nothing but of a survey for rebuilding the city with bricks and large streets." Within a few days of the fire three several plans were presented to the king for the rebuilding of the city, by Christopher Wren, John Evelyn, and Robert Hooke. Wren proposed to build main thoroughfares north and south, and east and west, and to demolish the churches in conspicuous positions, to form the most public places into large piazzas, to unite the halls of the twelve chief companies into one regular square annexed to Guildhall, and to make a fine quay on the bank of the river from Blackfriars to the

Twenty. His streets were to be of three magnitudes—80 feet, 60 feet, and 30 feet wide respectively. Evelyn's plan differed from Wren's chiefly in proposing a street from the church of St Dunstan's in the East to the cathedral, and in having no quay or terrace along the river. In spite of the best advice, however, the jealousies of the citizens prevented any systematic design from being carried out, and in consequence the old lines were in almost every case retained. But, though the plans of Wren and Hooks were not adopted, it was to these two fellows of the Royal Society that the labour of rebuilding London was committed. Wren's great work, which has covered his name with renown, was the erection of the cathedral of St Paul's, and the many churches lauded round it as satellites. Hooks's task was the humbler one of arranging as city surveyor for the building of the houses. He laid out the ground of the several proprietors in the rebuilding of the city, and had no rest early or late from persons soliciting him to set out their ground for them at once. The first great impetus of change in the configuration of London was given by the great fire, and Evelyn records and regrets that the town in his time had grown almost as large again as it was within his own memory. Although for several centuries attempts had been made in favour of building houses with brick or stone, yet the carpenters continued to be the chief house-builders. As late as the year 1650 the Carpenters' Company drew

up a memorial in which they "gave their reasons that timber buildings were more commodious for this city than brick buildings were." The Act of Parliament "for rebuilding the city of London" passed after the great fire, gave the *corps de grace* to the carpenters as house-builders. After setting forth that "building with brick was not only more comely and durable, but also more safe against future perils of fire," it was enacted "that all the outside of all buildings in and about the city should be made of brick or stone, except doorcases and window frames, and other parts of the first story to the front between the joists," for which substantial oaken timber might be used "for convenience of shops." A third severe blow in addition to the plague and the fire overtook London in the reign of Charles II. The king and his brother had long entertained designs against the liberties of the city, and for the purpose of crushing them two measures were set up—(1) that a new rate of market tolls had been levied by virtue of an act of common council, and (2) that a petition to the king, in which it was alleged that by the monopolization of parliament public justice had been interrupted, had been printed by order of the Court of Common Council. Charles directed a writ *quo warranto* against the corporation at London in 1683, and the Court of King's Bench declared its charter forfeited. Soon afterwards all the obnoxious aldermen were displaced and others appointed in their room by royal commission.

London in 1723. Redwood Facsimile of Map by J. Senex

A new lord mayor and recorder, and new sheriffs were appointed in the same manner. This decision of the Court of King's Bench was reversed in 1697. In the winter of 1685-86 a fair was held for some time upon the Thames. The flood, which commenced about seven weeks before Christmas and continued for six weeks after, was the greatest on record, the water was 11 inches thick.

The revocation of the edict of Nantes in October 1685, and the consequent migration of a large number of industrious French Protestants, caused a considerable growth in the east end of London. The silk manufactures at Spitalfields were then established.

During the short reign of James II. the fortunes of the city were at their lowest, and nowhere was the arrival of the prince of Orange more welcomed. One of the first acts of James was to cause an indictment for high treason to be prepared against Alderman Cornish, who had been a zealous supporter of the Exclusion Bill. Sir John Hyles, who had never been sheriff nor was even a freeman of the city, was appointed lord mayor by the king in 1688 in succession to Sir John Shorter. When James found the danger of his position, and learned that William had landed, he sent for the mayor and aldermen and informed them of his determination to restore the city charter and privileges.

William III. cared little for London, the smoke of which gave him asthma, and when a great part of Whitehall was burnt in 1691 he purchased Notingham House and made it into Kensington

Palace. For convenience of communication with London he had a broad road made through Hyde Park, which was lighted by lanterns at night. Kensington was then an insignificant village, but the arrival of the court soon caused it to grow in importance.

Although the spiritual wants of the city were amply provided for by the churches built by Sir Christopher Wren, the large districts outside the City and its liberties had been greatly neglected. The Act passed in the reign of Queen Anne for building fifty new churches (1710) not only helped to supply this want, but also gave a special architectural character to the suburbs.

EIGHTEENTH CENTURY.—With the accession of George I. a considerable change in the habits of all classes was introduced. At no previous time probably was public taste so low or manners more depraved. These two evils naturally were felt over the whole kingdom, but nowhere was their baneful influence more apparent than in the capital. Public buildings of the most tasteless character were raised, and streets of private houses were built that were positively painful in their ugliness. London thus grew to be the ugliest of cities, a character which it is only now beginning to throw off. London had gradually grown up by the side of the Thames and extended itself along the river's banks, which were skirted by a succession of handsome palaces. The inhabitants moved from place to place in boats, and the river was the chief highway. In the 18th century this state of things had ceased,

and other parts of the town were more largely built upon. The inhabitants used coaches and chaises more than boats, and the banks of the river were neglected. London could no longer be seen as a whole, and it grew into a mere collection of houses. In spite of all this the 18th century produced some of the most devoted of Londoners,—men who considered a day lived out of London as one lost out of their lives. Of this class Dr Johnson and Hogarth are striking examples. The exhibitions of vice and cruelty that were constantly to be seen in the capital have been reproduced by Hogarth, and had they not been set down by as truthful an observer it would have been almost impossible to believe that such enormities could have been committed in the streets of a great city. A few days after his accession George I. addressed the representatives of the city in these words:—"I have lately been made sensible of what consequence the city of London is, and therefore shall be sure to take all their privileges and interests into my particular protection." On the following lord mayor's day the king witnessed the show in Chancery and attended the banquet at Guildhall. Queen Anne and the first three Georges were all accommodated, on the occasions of their visits to the City to see the show, at the same house opposite Bow Church. In the time of Queen Anne and George I. David Barclay (the son of the famous apologist for the Quakers) was an apprentice in the house, but he subsequently became master, and in honour of receiving George II and George III as his guests. There was a large balcony extending along the front of the house which was fitted with a canopy and hangings of crimson damask silk. The building, then numbered 108 Chancery, was pulled down in 1831. In September 1739 the burning of the Scotch Saftmill created the most fearful panic that London has ever seen. Trade was at a standstill, and many of the chief merchants, goldsmiths, and bankers stopped payment, thus causing ruin to numberless families.

Early in the 18th century there was a considerable extension of building operations in the West End. About the year 1716 the earl of Burlington commenced building on the Ten Acres Field at the back of the gardens of Burlington House, and shortly afterwards the City authorities, who were proprietors of the Conduit Head (containing 27 acres), followed his example. On June 1, 1717, the *Weekly Journal* announced that the new building between Bond Street and Mary-le-Bone go on with all possible diligence, and the houses even let and sold before they are built. The parish of St. George's, Hanover Square, was constituted in 1728. In 1716 Cavendish Square and the neighbouring streets had been planned, and the plan was carried out with the completion of the foundation stone of Harcourt House (duke of Portland's) on the west side of the square, which is now about to be destroyed, was laid in 1722; and the north side, which was originally intended to be occupied by the mansion of the duke of Chandos, was still in 1760. The first church in the parish, Vere Street, originally Oxford chapel, was built by Gibbs about 1728.

Still, however, the north of London remained unbuild upon, and the open character of this part is well shown in the map given above. In 1760 and for some years subsequently the land behind Montagu House (now the British Museum) was occupied as a farm, and when in that year a proposal was made to plan out a new road the tenant and the duke of Bedford strongly opposed it. In 1772 all beyond Portland Chapel in Great Portland Street was country. Portman Square was laid out about 1764, but it was nearly twenty years before the whole was finished. It was built on high ground with an open prospect to the north, which gave it a name as a peculiarly healthy part of London. Mrs Montagu called it the Montpellier of England, and said she "never enjoyed such health as since she came to live in it." In a map of London dated 1778 the villages of Hackney, Stepney, Islington, Finsbury, Marylebone, Paddington, Knightsbridge, and Chelsea are all shown as country outside of the town. Bedford House in Bloomsbury Square had its full view of Hampstead and Highgate from the back, and Queen's Square was built open to the north in order that the inhabitants might obtain the same aspect. Dr Hoberden recommended South Lambeth as a health resort on account of its situation on the banks of a tidal river with the south-west wind blowing fresh from the country and the north-east softened by blowing over the town.

In 1737 the Fleet ditch between Holborn Bridge and Fleet Bridge was covered over, and Stocks market was removed from the site of the Mansion House to the present site. The market, called Fleet market, On October 26, 1738, the first stone of the Mansion House was laid. Previously this first magistracies lived in several different houses. In 1760 Westminster Bridge was opened for passengers, and London Bridge ceased to be the only means of crossing the Thames at the present site. The bridge followed in 1768. A boat almost as severe as the memorable one of 1683-84 occurred in the winter of 1789-90, and the Thames was again the scene of a busy fair. In 1768 the houses on London Bridge were cleared away, and in 1790-92 several of the city gates were taken down and sold. Morgate is said to have fetched £166, Aldersgate £91, Aldgate £177, Cripplegate £80, and Ludgate £146. The statue of Queen Elizabeth

which stood on the west side of Ludgate was purchased by Alderman Goelling and set up against the east end of St Dunstan's church in Fleet Street, where it still remains.

The need of improving and opening out many of the streets of London was felt in the 18th century, but little or nothing was done, and the work was left to be accomplished in the present century. John Gwynn, a friend of Dr Johnson, paid considerable attention to this subject, and published in 1766 a work entitled *London and Westminster Improved, Illustrated by Plans*. Many of the author's suggestions have not been carried out, although they would often have been improvements upon what has been actually accomplished. Of such suggestions as have subsequently been executed we may note here the widening of Swallow Street, a much-needed improvement, which was not carried out until the beginning of the present century, a square where Trafalgar Square now stands and some straight streets on the site of Drury Lane House now the Adelphi, and a bridge where Waterloo Bridge was afterwards built.

Robert Adam and his brothers, Scotsmen who came to London under the protection of the earl of Bute, made a considerable improvement in the appearance of certain parts of London during the second half of the 18th century by the adoption of a combined system of architecture, in which several separate houses were grouped together to give the appearance of a continuous building. The Adelphi and Portland Place still remain good examples of their system. The brothers Adam were leaders in the revival of taste, and the interiors of their buildings are executed with great elegant detail. We have now come to a period when London outside the City may be considered as more important in many points than London within the liberties. "Why not," said Dr Johnson to Boswell, "Fleet Street has a very animated appearance, but I think the tide of human existence is at Charing Cross." This speech was made in 1776, and in spite of the vast increase of London in every direction Charing Cross still retains this pre-eminent position.

The latter years of the 18th century were exceedingly turbulent ones for London, but it is only necessary here to barely indicate the divisions between the court and the City relating to the election of Wilkes, and the Gordon riots of 1780, when the gates of Newgate were thrown open, and much property was destroyed by the mob. "It is a disaster," it is a disaster—it is a disaster, and it is a disaster like a full account of the history of London during the 19th century. Since 1800 the City itself has been almost entirely rebuilt, and the suburbs on all sides have been vastly extended. Russell Square was built about 1801, and the district north of Bloomsbury where the land out at the same time. Bloomsbury Square had been built in 1685, and Bedford Square at the end of the 18th century. Alexander Gibson Hunter, in a letter to Countess the publisher written in March 1807, says, "Young Pindar and I walked over all the duke of Bedford's new feeling grounds, Russell Square, Tavistock Place, Brunswick Square, &c. The extent of them, and the rapidity of the buildings, is beyond all comparison." Bedford and Russell Squares were for some years the favourite place of residence for the judges. To show how late has been the growth north of the New Road we may mention that at the beginning of the century grapes were reaped by the sun in the open air in gardens in Gower Street, and twenty five dozens of new berries were gathered in 1800 from three completely exposed trees in a garden in Upper Gower Street. Still later the richest flavoured calery was gathered in abundance in the same place. When dwelling was in fashion the duellists naturally chose out the most unsegregated places, and we thus obtain an idea where these places were situated. Chalk Farm for some time rivalled in popularity Wimbledon Common, where the duke of York fought Colonel Lennox in 1780, Battersea Fields, where the duke of Wellington fought the earl of Winchester in 1829, and Putney Heath, where Pitt met Manners in 1793, and Castlereagh and Canning fought in 1809. As late as 1848 a duel was fought at Chalk Farm between Lieutenant Monro and Colonel Fawcett, when the latter was killed.

In 1808 London saw the public funeral of three of England's greatest men. On the 8th February the body of Nelson was borne with great pomp from the Admiralty to St Paul's Cathedral, where it was interred in the presence of the prince of Wales and the royal dukes. Pitt was buried on 22d February, and Fox on the 16th October, both in Westminster Abbey.

The first exhibition of Wm. Smeaton's system of lighting the streets with gas took place on the king's birthday (June 4) 1807, and was made in a row of lamps in front of the colonnade before Carlton House. Fire-bury Square was the first public place in which gas lighting was actually adopted, and Grosvenor Square the last. On October 11, 1811, the first stone of Waterloo Bridge was laid, and on June 18, 1817, it was publicly opened. Southwark Bridge was opened in April 1819, and new London Bridge, the first stone of which had been laid on June 15, 1825, on August 1, 1831. Westminster and Blackfriars Bridges were both widened in the last few years, and thus not one of the London bridge dates back farther than the present century. One of the greatest improvements in the West End was the formation of Regent Street, intended as a communication between Carlton House and the Queen's Park.

in 1881; and the value of the exports from £76,000 to £131,141. Three daily and five weekly newspapers and three monthly periodicals issue from the local press. The city is divided into seven wards, and is governed by a mayor and aldermen. First laid out in 1826-6, it returned a member in 1836, and was incorporated in 1840. The population was 15,826 in 1871, and 17,476 in 1881; but the East, West, and South London suburbs—really part of the city, though not yet included within the municipal boundaries—have a population of upwards of 10,000.

LONDONDERRY, a maritime county in the province of Ulster, Ireland, is bounded on the N. by the Atlantic, on the W. by Lough Foyle and Donegal, on the E. by Antrim and Lough Neagh, and on the S. by Tyrone. It has an irregular oval form, its greatest length being about 50 miles, and it greatest breadth about 40. The area comprises 513,388 acres, or about 802 square miles. The county consists chiefly of river valleys surrounded by elevated table-lands rising occasionally into mountains, while on the borders of the sea-coast the surface is generally level. The principal river is the Roe, which flows northwards from the borders of Tyrone into Lough Foyle below Newtown-Linnavady, and divides the county into two unequal parts. Further west the Faghlan also falls into Lough Foyle, and the river Foyle passes through a small portion of the country near its north-western boundary. In the south-east the Moyola falls into Lough Neagh, and the Lower Bann from Lough Neagh forms for some distance its eastern boundary with Antrim. The only lake in the county is Lough Finn on the borders of Tyrone, but Lough Neagh, which is included in Antrim, forms for about 6 miles its south-eastern boundary. The valley of the Roe is a line of division between two entirely different geological structures. To the east there is a basaltic tract in all respects similar to that in Antrim, except that on the Londonderry side of the Bann the dip of the strata is reversed and lies north-east. At Boneyvenagh, which has an elevation of 1262 feet, the basalt reaches a thickness of 800 feet. It is succeeded by chalk lias, limestone, and red sandstone, the whole resting on primitive rock. The remainder of the county consists chiefly of moor-plate and primitive limestone, and includes the mountain of Sawel, with an elevation of 2236 feet, as well as other eminences approaching 2000 feet in height. Horblende and granite frequently emerge above the slate, and limestone is not uncommon. Sandstone crops to the surface throughout nearly the whole of the valley of the Roe. Fine rock crystals are found in Finglen, near Dungiven, and in several other districts. Iron was at one time worked at Slieve Gullion, and is obtained in abundance in the bogs. There are a few unimportant veins of copper and lead.

Agriculture.—The excessive rainfall and the cold and uncertain climate are unfavourable for agricultural operations, and except in the valleys the soil is unsuitable for tillage. In the basaltic region large tracts are partially submerged, and the hard and firm portions consist chiefly of rock. Along the sea-coast there is an extensive district of red clay formed by the decomposition of sandstone, and near the mouth of the Roe there is an extensive tract of a marly nature. Along the valleys the soil is often very fertile, and the elevated districts of the clay-slate region afford rich pasture for sheep.

In 1880 131,286 acres were under tillage, 264,044 were pasture, 5308 plantation, and 120,451 waste. The total number of holdings in the same year was 17,851, of which 1877 were under 1 acre. More than half of the total number were included in those between 5 and 16 acres and those between 16 and 80 acres, which numbered 6447 and 4845 respectively. The following table shows the area under the principal crops in 1865 and 1881—

	Wheat.	Oats.	Other Cereals.	Potatoes.	Turnips.	Other Crops.	Flax.	Acres in Clover.	Total.
1865	9,303	91,909	9,664	31,883	11,641	1,464	11,796	28,779	154,837
1881	1,817	74,689	6,162	84,487	27,481	8,960	18,830	38,062	164,918

The increase in the area under crops is due chiefly to the increase in that under flax and meadow, although there is an increase in all other crops except wheat and oats.

The number of horses since 1865 has increased very slightly—from 20,381 to 20,749, of which 17,068 were used for agricultural purposes. Cattle in 1865 numbered 102,155, and in 1881 only 86,693, an average of 25 to every 100 acres under cultivation, the average for Ireland being 25.8. The number of milch cows was 39,893. Sheep numbered 29,688 in 1865, and 30,101 in 1881, pigs in the same years numbering 22,898 and 23,946. Goats in 1861 numbered 4666, and poultry 288,486.

According to the latest return, the land in 1873 was divided amongst 2178 proprietors possessing 511,838 acres, with a total annual value of £264,732, the annual value per acre being 15s. 4d. Of the owners about 83 per cent. possessed less than 1 acre. As many as 163,419 acres were possessed by the Irish Society and seven of the livery companies of London—the Irish Society possessing 675 acres, the Drapers' Company, 27,025, the Fullmerton's, 20,509, the Grocers', 11,638, the Ironmongers', 12,714, the Mercers', 21,214, the Salters', 19,446, and the Skinners', 34,772. In addition to this Sir H. Bruce owned 20,801 acres, S. G. Bruce 34,671, the representatives of T. R. Richardson 13,159, Chancery Commissioners 13,418, C. S. M'Causland 12,886, and J. B. Keirwood 10,420.

Manufactures.—The staple manufacture of the county is linen. In 1880 the number of scutching mills was 185. The manufacture of coarse earthenware is also carried on, and there are large distilleries and breweries and some salt-works. There are important fisheries of salmon and eels on the Bann.

Railways.—The only railways in the county are those which skirt its northern and western boundary, and which belong to the Belfast and Londonderry and Coleraine and Londonderry and Coleraine Companies, and another line connecting Londonderry with Enniskillen.

Administration and Population.—The county comprises 6 baronies, with 49 parishes and 1902 townlands. It is in the north-west corner. Assizes are held at Londonderry, and quarter sessions at Coleraine, Londonderry, Magherafelt, and Loughinisletty. Within the county there are 14 petty sessions districts. It includes two poor-law unions and portions of other three. Londonderry is in the Belfast military district and Omagh subdistrict. The county is represented in parliament by two members, and the borough of Londonderry (28,947) and Coleraine (6684) by one each. The population of the county, which in 1780 was only 46,182, had increased by 1821 to 168,886, and by 1841 to 222,461, but in 1851 had diminished to 192,269, in 1871 to 178,060, and in 1881 to 164,714, of whom 79,138 were males and 85,676 females. From the 1st May 1851 to 31st December 1881 the number of emigrants was 78,726. For every 1000 of the population the death-rate in 1880 was 19.2, the marriage-rate 4.5, and the birth-rate 23.2.

History and Antiquities.—At an early period the county was inhabited by the O'Connors, or O'Connors, who were tributary to the O'Neals or O'Neals. Towards the close of the reign of Elizabeth the county was seized with the purpose of changing the power of the O'Neals, when it received the name of Coleraine, in honour of that town for its capital. In 1609, after the confiscation of the estates of the O'Neals, the citizens of Londonderry obtained possession of the towns of Londonderry and Coleraine and adjoining lands, 60 acres out of every 1000 being assigned for church lands, and certain other portions to three native Irish gentlemen. The citizens of Londonderry undertook to expend £20,000 on its reclamation, and elected a body of twenty-six for its management, who in 1613 were incorporated as the Irish Society, and retained possession of the towns of Londonderry and Coleraine, the remainder of the property being divided among twelve of the great livery companies of the city. Notwithstanding the expenditure of large sums by these companies in its management, their estates were afterwards sequestered by James I., and in 1637 the charter of the Irish Society was cancelled. Cromwell restored the society to its former position, and Charles II. at the Restoration granted it a new charter, and confirmed the companies in the possession of their estates. In the reclamation of 1641 Magherafelt was seized by the Irish, and Magherafelt and Bellaghy, then called Vintner's Down, burned, as well as other towns and villages. The most remarkable ancient ruin is that of the Cyclopean fortress of the Giant's Scourie or Ring, situated in the pass between Drumbo and Larne, the interior of which, 600 feet in length, is partially hollowed out of a knoll of boulder, by which it is enclosed on all sides except the north-east, where it is defended by a wall of great thickness, with access for only one person in a stooping posture. The most remarkable of the Druidical circles is that at Slieve

MAONS There are a large number of artificial caves. The most ancient castle of Irish origin is that of Carrucknaghy; and of the castles erected by the English those of Dungiven, Salterstown, and Meaf are still in good preservation. The old abbey of Dungiven, founded in 1109, and standing on a rock about 200 feet above the river Roe, is a very picturesque ruin.

LONDONDERRY, or DERRY, a county of a city, parliamentary borough, and the chief town of the county of Londonderry, is situated on an eminence rising abruptly from the west side of the river Foyle to the height of about 120 feet, 4 miles from the junction of the river with Lough Foyle, and 80 miles north-north-west of Belfast. It is still surrounded by an ancient rampart about a mile in circumference and having seven gates, but the buildings now extend considerably beyond this boundary. The summit of the hill, which is at the centre of the town, is occupied by a quadrangular area from which the main streets, which for the most part are spacious, diverge at right angles. Some of the original houses with high pyramidal gables remain, but they have been much modernized. The river is crossed by an iron bridge 1200 feet in length. The cathedral in the Later English style, and consisting of nave and aisles separated by pointed arches, with tower and spire at the west end, was completed in 1633 at a cost of £4000, contributed by the city of London. The building is 240 feet in length with a breadth of 63 feet, and the height of the tower and spire is 228 feet. The spire was added in 1788, when the old tower was raised 21 feet, and in 1802 the spire was rebuilt. The bishop's palace, erected in 1716, occupies the site of the abbey founded by Columba. The abbot of this monastery, on being made bishop, erected in 1164 Temple More or the "Great Church," one of the finest buildings in Ireland previous to the Anglo-Norman invasion. The original abbey church was called the "Black Church," but both it and the "Great Church" were demolished in 1600, and their materials used in fortifying the city. There is a large Roman Catholic cathedral. The court-house was completed in 1824 at a cost of about £24,000. For the free grammar school, founded in 1617, a new building was erected in 1814 at a cost of over £14,000. There are a number of charitable foundations. The staple manufactures of the town is linen, and there are also shipbuilding yards, iron foundries, saw-mills, munition-works, distilleries, breweries, and flour-mills. The salmon fishery on the Foyle is also very valuable. The river affords facilities for a secure and commodious harbour, its greatest depth being 33 feet, with a depth of 12 feet at low water. The port has a considerable coasting trade with Great Britain, exporting agricultural produce and provisions. For the last five years its imports have averaged over £500,000 (chiefly grain and provisions), and its exports, which vary very greatly, over £10,000. In 1880 the number of vessels that entered the port was 1569, with a total tonnage of 335,544, the number that cleared 1452, with a tonnage of 326,178. Londonderry returns one member to parliament. The population of the city, which in 1867 was 19,399, had increased in 1871 to 23,242, and in 1881 to 28,947.

Derry, the original name of Londonderry, is derived from *Dobru*, the "place of oaks." It owes its origin to the monastery founded by Columba in 546. From the 9th to the 11th century the town was frequently in the possession of the Danes, and was often burned and devastated, but they were finally driven from it by Muringh O'Brien about the beginning of the 12th century. In 1811 it was granted by Edward II. to Richard de Burgo. After the Irish Society of London obtained possession of it, it was in 1613 incorporated under the name of Londonderry. The fortifications which were begun in 1600, were completed in 1618 at a cost of nearly £9000. Its charter was confirmed in 1662 by Charles II. From April 18, 1690, the Protestants of the north defended themselves within its walls against James II., until the siege was raised in the following August. See the *History* by Hempton (1851).

LONDONDERRY, ROBERT STEWART, SECOND MARQUIS OF (1769-1822), better known by his courtesy title of Viscount Castlereagh, which he held until the last year of his life, the statesman who brought about the union with Ireland, who was foreign minister for ten eventful years, who represented England at the congress of Vienna, and who was the recognized leader of the aristocratic and reactionary party which owed its being to the excesses of the French Revolution, was born on June 18, 1769, and was thus one year older than his great rival George Canning. His father, Robert Stewart of Ballylawn in the county of Londonderry, and Mount Stewart in Down, had represented the latter county in two Irish parliaments; and his marriage with Lady Sarah Seymour Conway, daughter of the earl of Hertford, in 1766, had brought him into connexion with many of the great Whig families of England, as did also his second marriage with the eldest daughter of Lord Camden. His elder son, the future minister, was educated at a school in Armagh, and proceeded in 1786 to St John's College, Cambridge. He spent only a single year at the English university, and was on his grand tour through Europe when he was summoned home by his father, who had just been created Lord Londonderry in the peerage of Ireland, to stand for the county of Down as the candidate of the smaller landholders against the influence of the marquis of Downshire. The election cost the new Lord Londonderry £60,000, a sum which crippled him for his whole life. But he was successful, and the young Stewart entered the Irish parliament as one of the few really independent members who sat there, bound by no ties to a great lord, but the representative of three thousand freeholders of the richest county of the most educated province of Ireland. He joined the opposition, like his father before him, and eagerly pressed for the extension of the franchise to the Roman Catholics, even going so far, and his enemies later, as to become a contributor to the *Northern Star* of Belfast, the organ of the seditious party in Ulster; but the great events of the French Revolution soon showed their influence on his opinions, as on those of most landed proprietors. His thoughts on politics already clearly pointed towards the necessity of a union between England and Ireland, a necessity by this time obvious to all political thinkers and practical politicians. But for the time he held firmly to the popular side, voting for the removal of Catholic disabilities, and the right of Irishmen to trade with India. At last, however, Lord Camden came over to Ireland, in March 1795, as lord-lieutenant, with Mr Pelham as his secretary, on a mission to tell the Catholics and reformers that they must expect no further relief and no further reform. He took much notice of his sister's step-son, young Robert Stewart, who was quite willing to be won over from the opposition, and who had in the previous year married Lady Emily Hobart, daughter of the late earl of Buckinghamshire, and near relative of many great political personages. Lord Camden used his influence to obtain for his brother-in-law a viscountcy as Viscount Castlereagh in October 1795, and in the following August an earldom as earl of Londonderry. In that same August 1796 he made Robert Stewart, who by his father's promotion had become Viscount Castlereagh, keeper of his signet, an honorary post which merely marked his accession to the Government, and in February 1797 acting secretary in the place of Mr Pelham. Taking office at a time when everything was at the height of confusion, Lord Castlereagh soon began to show his splendid administrative genius, which, indeed, consisted in his "finite capacity for taking pains" and careful mastery of details. During the rebellion of 1798, when Lord Camden resigned in panic, Castlereagh showed all the qualities of a splendid

minister of police, and heartily co-operated with the wise measures of Lord Cornwallis, by which the rebellion was soon brought to an end. He was equally useful to Cornwallis in the second part of his mission to Ireland, namely, the union with England. The measure was to be carried; the means were bribery whether in honours or in money. The details of the passage of the measure through the House can be studied in the correspondences of Cornwallis and Castlereagh, in which appear clearly the utter disgust of Cornwallis at the work he was doing and the country he was in, and Castlereagh's pride in his successful manipulation of men. The Union carried (1800), then came the fulfilment of promises made to secure support or disarm opposition, and first in importance those to the Catholics. It was thoroughly understood between Pitt, Cornwallis, and Castlereagh that full rights of citizenship were to be given to the Catholics as a reward for the loyal behaviour of the greater men during the rebellion, and to induce them not to oppose the Union. But the promise was not fulfilled. Pitt had indeed promised to carry the measure; but the king's conscience was worked upon by Lord Loughborough, and to Pitt's surprise and disgust his resignation was accepted, and immediately followed by that of the ablest half of the cabinet, and necessarily of Cornwallis and Castlereagh. With his resignation ends the first epoch of Castlereagh's political life. On very many occasions in his correspondence Cornwallis mentions him with warm praise of his "talents, temper, and judgment," and only qualifies his opinion in one place, when he says, on July 3, 1800, that "Littleholes very much surpasses Lord Castlereagh in the private management of mankind from his good humour and kind attention to everybody." Here Cornwallis touches the greatest political fault of Castlereagh, which destroyed his popularity and ruined his reputation—his want of sympathy for human weaknesses.

Castlereagh was sworn of the English privy council in December 1799, and returned to the first united parliament for the county of Down. He had no intention of permanently losing office by his advocacy of the Catholic claims, and therefore, instead of going into violent opposition like Canning and others of the late administration, he supported the weak Addington ministry, and in June 1802 was appointed president of the Board of Control. On Pitt's return to power in December 1804 he kept Castlereagh in office, and in 1805 made him secretary of state for war and the colonies, as well as president of the Board of Control. For the six months he held the war office he was Pitt's right hand in administration, as Canning was in debate. He now prepared a great expedition of thirty thousand men, who were to land in Hanover and make a diversion in northern Germany in favour of the Russians and Austrians. The expedition was too late to be of any use, but it deserves notice as illustrating Castlereagh's favorite idea that England should carry on "a grande guerre," which was to appear to a greater extent later. His present tenure of office was but short, for Pitt's Government resigned on his death in January 1806.

When Pitt died, Castlereagh was prime mover in the attempt to make Lord Hawkesbury premier, and when that failed, sooner than give up all hope of place, he declared that he and his friends "looked to." Lord Grenville. Grenville, however, formed his ministry of "all the talents" out of the sections which followed Fox, Windham, and Sidmouth. The opposition was led in the House of Commons by Castlereagh and Canning. Now began the close association of these two celebrated men, each of whom hoped to lead the Tory party, and who did so in turn, both Irishmen from the same county of Londonderry, both in the prime of life, and distinguished

—the one for his surpassing eloquence, the other for his administrative powers. Each rival despised the other. Castlereagh, conscious of his high birth and noble connections, looked down on the son of the actress. Canning, conscious on his side of his great talents for debate, looked down on the dunny debater and laborious parliamentary tactician, who looked to governing the country rather by a careful manipulation of boroughs and patronage than by eloquence and statesmanship. Castlereagh again, proud of his position as an ex-cabinet minister, pretended to lead Canning, who had held but inferior posts, while Canning, in his ardent devotion to the memory of Pitt, sneered at the man who had taken a seat in Addington's cabinet. This rivalry was increased almost to personal dislike by the marriage of Castlereagh's sister to the son and heir of that uncle of Canning's, Paul, in whose favour his own father had been disinherited, and who some years later was made Lord Garvagh. The rivals were not long in opposition, the new ministry resigning in 1807. The duke of Portland formed a new administration on strictly anti-Catholic principles, in which Castlereagh and Canning, both advocates of the Catholic claims, were secretaries of state, the former for war and the colonies, the latter for foreign affairs. During the two years they remained in office together each chafed at the other. The chief events connected with the war office during this tenure of office were the expeditions to Copenhagen, the Peninsula, and Walcheren. Of the Copenhagen expedition the chief credit or discredit must rest with Canning, but the merits of its execution rest entirely with Lord Castlereagh, who showed himself a war minister far superior to Dundas and Windham, and despatched in perfect secrecy a large military and naval expedition, which was swiftly and entirely successful. On the subject of the Portuguese expedition and the assistance to be afforded to the Spanish insurgents, the two secretaries were of different opinions. Canning sent the Spaniards officers, money, and arms in profusion, but was reluctant to send a great army, while Castlereagh planned the Portuguese expedition, chose Sir A. Wellesley to command it, and deserves the credit of Vimiera. Napier in his *Penninsular War* proves how wrong Canning was, how impossible it was to organize out of the Spaniards a force able to resist Napoleon, and how right Castlereagh was in believing in the efficiency of a British army. The Walcheren expedition went far utterly to ruin Castlereagh's reputation, and completed the difference between Canning and himself. Yet the conception was good. Castlereagh prepared the expedition with skill and secrecy, though with slight regard for men's lives, as appeared in his choice of the unhealthy island of Walcheren for debarkation, and in his refusal to send enough doctors or hospital ships, and in his appointment of Lord Chatham to command in chief. In this appointment of Chatham appears the radical vice of his war administration: he looked before giving a command on active service to parliamentary influence, not tried ability. The failure of the expedition brought about a crisis in the cabinet. In April 1809 Canning had sent in his resignation to the duke of Portland, declaring that he could no longer serve with Castlereagh, but the matter was put off from time to time, and at length Canning consented to wait till the Walcheren expedition was over. In September he insisted once for all that something must be done, and then for the first time Castlereagh heard that his dismissal had been determined on for some months. He was naturally indignant, and, being unable to challenge Lord Camden, his benefactor, who had really behaved worst to him, or the old duke of Portland, he challenged Canning, who had throughout protested against the manner in which Castlereagh had been treated. On September 21 they met

on Putney Heath, when Canning was slightly wounded in the thigh, and Castlereagh had a button shot off his coat. After this duel both resigned, and remained out of office two years, but Castlereagh did not intend to remain so, and through the influence of his aunt, old Lady Hertford, with the prince regent he was, after the refusal of Canning, offered the secretaryship of state for foreign affairs in March 1812 in the room of Lord Wellesley. On Perceval's assassination in May 1813, the leadership of the House of Commons was given to Castlereagh. The first ten years of Lord Liverpool's administration were the palmy days of the Tory aristocracy, and during them Lord Castlereagh was the guiding spirit of foreign policy in the cabinet, and the faithful interpreter of Lord Sidmouth's home policy in the House of Commons. Once in power, he perceived that Napoleon must be beaten in Germany, and that, though Lord Wellington's army in Spain must be supported to maintain the credit of English soldiers, and occupy as many French troops as possible, the important point was for the Russian and Prussian monarchs to be joined by the Austrian emperor, and follow up the blow Napoleon had dealt himself in his invasion of Russia. To bring Austria into the field, manage the crown prince of Sweden, maintain the alliance of the great powers and the harmonious working of their armies and policies, Castlereagh gave the English ambassadors at the courts of Austria, Russia, and Prussia, full powers to correspond with each other, and follow the allied forces. The ability with which these instructions were carried out is to be read in the history of the whole campaign of 1813, and of the congresses of Mannheim and Frankfurt. When the allies entered France, Castlereagh himself left England to attend the congress of Chatillon. He remained with armies of the allies, entered Paris with them, and signed the preliminaries of peace. Great was the applause he received on his return from the people, and above all in the House of Commons. The prince regent made him a Knight of the Garter, an honour which had only been conferred on two commoners, Sir H. Walpole and Lord North, for the last two hundred years, and when the allied sovereigns visited London they treated him with marked favour, so that it was no wonder, when he started to take his seat as British plenipotentiary at the congress of Vienna, he believed himself to be a great diplomatist. That he was mistaken in this was conclusively proved by that congress where, as Von Gentz said, England could have done anything, and did nothing. Throughout he supported Metternich, partly because Metternich's nature had mastered him, but more because he had imbibed a blind distrust of Russia. When the return of Napoleon from Elba put an end to the quarrels which were nearly ending in a general war between Prussia and Russia on the one side and England, France, and Austria on the other, and united all parties against him, Castlereagh returned to England, and expressed his confidence in a speedy termination of the new struggle, which indeed was closed at Waterloo. He signed the second peace of Paris on behalf of England, and on his return his father was created marquis of Londonderry. From this time his career can be sketched very shortly. At home the grand harvest of 1815 was followed by very bad ones, and great discontent existed both among the agricultural and manufacturing classes. The Government pursued the same tactics which had in 1793 united nearly all the upper classes in a fever of reaction; they established a secret committee which declared the existence of a widespread conspiracy, and it was often their spies who threw into the meetings of the discontented sufficient politics to make them look like conspiracies. The bad feeling existing came to a climax with the Peterloo massacre, and Lord Sidmouth introduced his Six Acts to check a network

of conspiracies which mostly did not exist. Castlereagh had to introduce the Six Acts in the House of Commons, and as usual spoke of the people with the air of hauteur and contempt which made him so particularly obnoxious to them. His foreign policy during these years was chiefly inspired by a real desire to maintain the peace of Europe, which he believed was only to be preserved by the harmony of all the monarchs and their foreign ministers, and to preserve this harmony he was so loth to differ from them on any subject that it was commonly believed among the people that he had signed the Holy Alliance. At the congress of Aix-la-Chapelle in 1818 it was for this reason that he recommended that France should be freed from the army of occupation. The death of George III. in January 1820 made no difference to Castlereagh, who was greatly in the favour of the new king, and who had no difficulty in supporting the Bill of Pains and Penalties against the queen. Scarcely was the excitement of the queen's trial and the king's coronation over, when Lord Londonderry, for he had succeeded to that title in this very year, accompanied the king to Hanover in October 1821 to discuss the revolutions in Greece and Spain with Metternich. The interviews which then took place are fully described in Metternich's *Autobiography* (vol. iii. pp. 552-560), and exhibit clearly the paramount influence of Metternich over Lord Londonderry, whom he persuaded to take part in a congress at Verona in the following year. While he was making preparations to start, he became possessed by many strange delusions, which clearly indicated that his mind was unbalanced by overwork, as it had been once before after the passing of the Union with Ireland. This soon became obvious to every one, the king noticed it; and the duke of Wellington sent a physician down to Fonthill to see him. The doctor found him suffering from melancholia, and ordered his razors to be taken away, but in spite of all precautions he procured a penknife and committed suicide on August 12, 1822. His body was conveyed to London to be buried in Westminster Abbey, and just as it was being lowered into the grave a cry of exultant hatred arose from that rabble he had so despised.

Castlereagh's character illustrates the strange difference which in corrupt times can exist between public and private morality. In private life he was a strictly honourable and affectionate man; he was a good husband, a good son, a good brother, and a good master; but even in his private relations that want of warmth which made Cornwallis declare he was utterly unlike an Irishman, and Wilberforce liken him to a fish, seems to have existed, and seems to have been part of his temperament. In public life he played quite a different part, and though he had one or two firm political principles, as appears in his steady advocacy of Catholic emancipation, he seems as a rule to have regarded politics as a game, in which all means were fair to win, and very extraordinary some of his means appear to be. Though a very bad and confused speaker, he was very successful as a parliamentary leader, from the care with which he used his patronage, and the amount of votes he won by it. While not a great diplomatist, as the mastery Metternich obtained over him clearly proved, as an administrator he deserves the highest praise, steadily punctual to his work, never allowing arrears to accumulate, and never neglecting a detail; but his parliamentary necessities stood in his way; every appointment was given from a party point of view, and if, as in the case of Sir A. Wellesley, chance sometimes led him right, jobbing more often led him wrong. But the chief interest which centres in Lord Londonderry is that he was the last leader of an extinct class. The old aristocrats who lived by politics, and thought all means fair in politics, are gone

for ever, and with Londonderry's death the unnatural tension of the reaction from the excesses of the French Revolution ceased, and modern Conservatism, containing indeed many prejudices and an exaggerated admiration for what is fixed, came into being with its real sympathy for all mankind, which the old Tories, and more especially Lord Londonderry, would have deprecated.

The best materials for studying Londonderry's life and opinions are his *Despatches* edited by his brother, the third marquis, in 19 volumes. They are, however, very incomplete from the loss of the most valuable at sea in the wreck of the ship which was taking Mr. Turner, Lord Londonderry's chosen biographer, to India. The *Correspondence* for his Irish work, and the supplementary *Wellington Despatches* should also be used. Alison's *Lives* of Lord Castlereagh and Sir Charles Stewart are interesting readings, but abound with that celebrated author's usual faults, and should be corrected by Walpole's *History of England* from 1815. Of contemporary diaries, Rose's, Lord Colchester's, Remilly's, and Wilberforce's, with Pellet's *Life of Lord St. John*, should be consulted, and Metcalf's *Autobiography* for the latter foreign policy. Mr. Thorneycroft has a short biography in his *Lives of the Foreign Secretaries from 1800*, which is chiefly valuable from his access to the unpublished memoranda of Lord Bexley, who as Mr. Valentia was chancellor of the exchequer, and helped to lead the Commons from 1812 to 1822. (H. M. S.)

LONG, GEORGE, an English scholar (1800-1879), was born at Ponton in Lancashire, on the 4th of November 1800. From Macclesfield grammar school he went to Trinity College, Cambridge, in 1818. He was elected Craven university scholar in 1821, together with Lord Macaulay and Professor Malden, took his degree in 1822 as wrangler and senior chancery medalist, and the next year gained a fellowship over the heads of his two distinguished rivals. In 1824 Long went out to be professor of ancient languages in the new university of Virginia. There he married his first wife, the widow of Colonel Selden. In 1828 he returned to England to accept the Greek professorship in the newly-founded university of London. His introductory lecture in 1828 was followed in 1830 by another entitled *Observations on the Study of the Latin and Greek Languages*. The etymological appendix to this lecture is of interest in the history of classical philology in England, as illustrating the scientific comparative method of teaching the Greek and Latin languages first adopted in the London university by himself and his colleague, Professor Key. He published a *Summary of Herodotus* (1829), and editions of Herodotus (1830-33) and Xenophon's *Anabasis* (1831). He was one of the founders of the Royal Geographical Society in 1830, and was for twenty years a member of the council, or officer of the society; in the same year he joined the committee of the Society for the Diffusion of Useful Knowledge, and was till 1846, when the society was dissolved, one of its most active workers. In 1831 he resigned his professorship and became editor of the society's *Quarterly Journal of Education* (1831-35), for which he wrote many articles. He wrote for the society's Library of Entertaining Knowledge the two volumes of *The British Museum: Egyptian Antiquities* (1832-36), and edited, improved, and wrote parts of the companion volumes *Elgin and Phigaleian Marbles* (1833) and *Townley Marbles* (1836). He planned and edited for the Library of Useful Knowledge a *Geography of America and the West Indies* (1841), of which he wrote a small part, and a *Geography of Great Britain. Part I. England and Wales*, part of which he also wrote himself. He contributed two maps of Egypt and Persia, ancient and modern, to the society's *Atlas* (1831). From 1833 to 1846 he was engaged on the great labour of his life, the editing of the twenty-nine volumes of the *Penny Cyclopædia*, to which he was also an extensive contributor of articles. The committee appointed Long and Charles Knight editors, but after the publication of a few numbers Knight took no part in the superintend-

ence of the work, and all the editorial labour was done by Long.

A more colossal and the final venture of the society was its *Biographical Dictionary*, of which Long was also appointed editor. He wrote numerous articles in the seven volumes which appeared (1842-44), but the great expense did not allow it to proceed beyond the letter A. Long was also a member of the committee of the Society for Central Education, instituted in London in 1837, and contributed two essays to its *Second and Third Publications* (1838-39). In 1837 he was called to the bar at the Inner Temple. He accepted in 1842 the professorship of Latin in University College, vacated by his friend Mr. Key, which he resigned in 1846, on being appointed by the benchers of the Middle Temple their reader on jurisprudence and the civil law. Two Discourses delivered in the Middle Temple Hall, with an Outline of the Course, were published in 1847. He wrote all the articles on Roman law in the *Dictionary of Greek and Roman Antiquities*, edited by Dr. William Smith (1842), and contributed also to the companion *Dictionaries of Biography* (1844-49) and *Geography* (1854-57). His translation of thirteen of Plutarch's *Lives*, with copious notes, first came out in five of Knight's weekly volumes under the title *The Great Warring Rome* (1844-48). He planned and edited Knight's *Political Dictionary* (1845-46), a revision of articles from the *Penny Cyclopædia*. Knight published in parts his *History of France and its Revolutions*, 1789-1848 (1850).

In 1849 he left London and went to Brighton College, where he was classical lecturer until midsummer 1871. He was an excellent teacher, and was beloved by both masters and pupils. Whilst here he edited, at first jointly with the Rev. A. J. Maclean, and after that gentleman's death by himself, the *Bibliotheca Classica* series, to which he himself contributed the edition of Cicero's *Orations* (1851-52), a task for which his legal knowledge eminently qualified him. He also revised, making many corrections and additions, Maclean's editions of Juvenal and Persius (1867) and Horace (1869). He made for Bell's Grammar School Classics editions, with introductions and notes, of Cicero's *De Senectute* and *De Amicitia*, with a selection from his *Epistulae* (1850), Caesar's *Gallia* (1853), and Sallust's *Catalina* and *Jugurtha* (1860). He also edited an *Atlas of Classical Geography* (1854). His translation of *The Thoughts of the Emperor M. Aurelius Antoninus* was published in 1862. The same year appeared anonymously the amusing and instructive little volume called *An Old Man's Thoughts about Many Things*. He was sixty-four when he issued the first of the five large octavo volumes of his *Decline of the Roman Republic*. In 1871 he resigned his post at Brighton College, and retired to Portfield, Chichester, to take a rest well-earned but from labours ill-rewarded. In 1873 the Queen, on the recommendation of Mr. Gladstone, granted him a pension of £100 a year. At Portfield he completed his *Roman History* (1874), and translated *The Discourses of Epictetus, with the Enchiridion and Fragments* (1877). This was the last work of his laborious and useful life. He died after a long and painful illness on the 10th of August 1879.

In addition to the works already noticed, Long was the author of two papers in the *Journal of the Royal Geographical Society*, a few in the early numbers of the *Penny Magazine*, and several in the *Classical Museum and English Journal of Education*. He also wrote on "Grammar Schools," in Knight's *Store of Knowledge*.

Long has exercised by his writings, and indirectly through some of his London university pupils, a wide influence on the teaching of the Greek and Latin languages in England. The publication of the *Bibliotheca Classica* (began in 1851) did important service, and set English scholars an excellent example, at a time when editions with English notes containing accurate learning and sound scholarship were, with very few exceptions, not to be found. Some of the volumes of this series still remain the standard

English editions. In the knowledge of Roman law Long stood by himself amongst English scholars, and his well-known articles on that subject were the first valuable contribution to the study from any English writer. He had also a profound knowledge of ancient geography. He was an excellent French, German, and Italian scholar, and also read Spanish. His extensive and accurate learning may be explained from the combination of a tenacious memory with a clear judicial intellect. His character was as elevated as his intellect. His simplicity and manly independence may be seen partly in his writings. His faculty for discriminating evidence and his strong common sense appear in everything that he wrote.

(H. J. M.)

LONG BRANCH, a fashionable seaside resort of the United States, in Ocean township, Monmouth county, New Jersey. The old village lies about a mile inland, but the watering-place proper is for the most part situated on the bluffs and plateau immediately above the beach. The bathing-grounds are excellent; there are fine drives along the beach in the vicinity; upwards of twenty thousand visitors can find accommodation in the hotels alone, of which there are no less than thirty-three, and there are besides hundreds of private residences occupied mainly by the wealthier classes from New York and Philadelphia. Since 1874 it can be reached directly from New York both by railway and by steamers. Long Branch has a corporation of seven commissioners. Its permanent population in 1880 was 3633, in 1882 about 5000.

LONGEVITY is a term that may be applied to express either the length or duration of life of any organism, or the prolongation of life to an advanced age. The first meaning is the more scientific of the two, as it may be applied to the duration of the life of any organism, although that duration may be relatively short; thus, we may contrast the longevity of the mould which lives only a few hours with that of the forest tree which has survived for centuries, or the longevity of the ephemeral insect with that of an eagle or a swan, whose lives may be prolonged to over a century. On the other hand, the second meaning is the more common, as when an instance of very advanced age is spoken of as an example of great longevity.

The information we possess as to the natural duration of life of the lower forms of plants and animals is very meagre, and it can scarcely be asserted that in all there is a natural period of life. A simple organism composed of cells, or even one more complicated but still having the organs necessary to life constructed upon a simple type, may continue to live and grow so long as external conditions are favourable. There may be no tendency to decay of tissue inherent in the organism, so that life may be prolonged until a change in external conditions, quickly or slowly, so affects the processes of nutrition as to make the continuance of life impossible beyond a certain time. It is also highly probable that in both the animal and vegetable worlds comparatively few individuals are permitted to live undisturbed for a sufficient length of time to allow any inherent tendencies to decay to show themselves. In the struggle for existence few individuals even reach maturity; at an early period they are used to support the lives of other and perhaps stronger organisms.

Excluding the lower forms of plants, as to the duration of whose lives we know nothing, the higher plants may be classed, according to duration of life, as follows:—*annuals*, or *semi-annuals*, which grow up in spring and die in autumn; *biennials*, which die at the end of the second year; and *perennials*, the duration of which may last from four to thousands of years. Succulent plants have a short life, lasting only one or two years; the formation of wood is necessary for prolonged vegetable existence. It has been pointed out that strongly scented plants have often a longer duration of life than those destitute of smell. Thus thyme, mint, hyssop, marjoram, sage, &c., can live for two years or longer; whilst lettuce, wheat, oats, barley, live no more

than a year. Trees of rapid growth, such as fir, birch, horse-chestnut, form soft wood, and have a comparatively short life; whilst hard-wood trees, such as the oak, grow slowly and live long. It is not, however, an invariable rule that trees yielding hard wood live longest. The beech, cypress, juniper, walnut, and pear all form hard wood, but they do not live so long as the lime, which forms a softer wood. Trees which are long in producing leaves and fruit, and which also retain these for a long time, live longer than those in which these changes occur quickly. Fruit-bearing trees, producing a sour harsh fruit in the wild state, have longer lives than those bearing sweet fruits in the cultivated state. By skilful pruning, or lopping off the branches and buds, the term of life of even short-lived plants may be lengthened.

According to Hufeland, the chance any plant has of attaining a great age depends on the following conditions:—(1) it must grow slowly, (2) it must propagate slowly and late in life, (3) it must have a certain degree of solidity and hardness in its organs, a sufficiency of wood, and the sap must not be too watery; (4) it must be large and have a considerable extent of surface, and (5) it must rise into the atmosphere. If we view a tree as consisting of an enormous number of buds clustered on a common stem in which the vessels or channels for the circulation of the sap remain pervious, and in which also new wood is formed annually, there seems to be no limit to age, provided external conditions are favourable. Many large trees have reached a vast age, as shown by the following table compiled by De Candolle:—

	Years		Years
Dim (<i>Ulmus campestris</i>) ..	385	Oriental plane (<i>Platanus orientalis</i>)	723
Olive (<i>Oleaceae sempervirens</i>) ..	525	Cedar (<i>Cedrus Libani</i>) ..	800
Chestnut (<i>Castanea vesca</i>) ..	400	Lime (<i>Fraxinus excelsa</i>) ..	1076-1127
Fir (<i>Abies balsamifera</i>) ..	400	Oak (<i>Quercus Robur</i>) ..	1100, 1200
Larch (<i>Larix europæa</i>) ..	675	Yew (<i>Taxus baccata</i>) ..	1214, 1468
Chestnut (<i>Castanea vesca</i>) ..	600		1260
Orange (<i>Citrus Aurantium</i>) ..	800	Paradise distichum ..	3000-4000
Palms (<i>Corymbus and Cocco</i>) ..	100-750	Isobol (<i>Adiantum digitata</i>) ..	3000
Grove (<i>Alnus europæa</i>) ..	700		

In the animal kingdom there is great variety as regards the duration of life, but no accurate data have yet been collected. Certain *Infectoria* have been watched during the whole period of their existence, which has not lasted more than forty-eight hours; on the other hand, *Actinia*, or sea anemones, may live to a long age, as shown by the case of a specimen of *Actinia mesembryanthemum*, still alive in Edinburgh, which belonged to Sir John Dalyell, and which must be at least about seventy years of age. It is highly probable that cold-blooded animals, such as fishes, frogs, toads, in which tissue-changes go on with extreme slowness, especially during a period of muscular inactivity, may live for many years. In the imperial fish-ponds of ancient Rome lampreys were said to have attained their sixtieth year; pike and carp have been ascertained to live a hundred and fifty years; tortoises have reached the age of one hundred years; and it is alleged by natives of India that the crocodile may live for at least a hundred years, and that there seems to be no limit to its time of growth. Many birds have a long period of life. Eagles and crows have been known to live a hundred years, and parrots have been kept in confinement for sixty years. Peacocks attain an age of twenty years; barn-door fowls live for a much shorter period, from six to twelve years. Small birds seem to have shorter lives than large ones. Blackbirds, goldfinches, and canaries have been known to live for twenty years, but many of the smaller birds attain an age of only five or six years.

Amongst mammals, the elephant is supposed to attain the greatest age, reaching above a hundred years; the camel generally lives to fifty years, and may live to eighty; the horse does not live more than forty years; the deer, thirty years; the ox, fifteen to twenty years; sheep, goats,

foxes, hares, rabbits, from seven to ten years; and dogs and pigs from fifteen to twenty years. Certain general statements may be made, which do not deserve to be termed laws, but which briefly express relations that undoubtedly exist in many cases between the degree of longevity enjoyed by any species of animal and the conditions of its existence.

1. A relation can often be traced between the duration of life and the time of the development of the animal *in utero*. To this statement there are many exceptions, as will be apparent from the following table, in which the periods of gestation are given on the authority of Professor Owen (*Comp. Anat. and Phys. of Vertebrates*, vol. iii.).—

Name	Period of Gestation in Days	Longevity in Years	Name	Period of Gestation in Days	Longevity in Years
Elephant	630	100	Monkey (Orang)	160	10
Giraffe	440	Not known	Pig	120	15-20
Norse and Ass	300	10-40	Manatee	120	Not known
Cow	280	15-20	Walrus	100	Not known
Human Being ..	280	70	Long	90	15-30
Roebuck	260	20	Cat	60	15-20
Red Deer	240	20	Wolf	60	Not known
Yellow Dog	240	20	Badger	40	Not known
Procyon	240	Not known	Kingfisher	35	Not known

In the case of birds no relation of this kind can be discovered. For times of incubation of many birds see Owen, *op. cit.*, vol. ii. p. 267.

2. It would appear that the sooner a being attains maturity the sooner it propagates, and the shorter will be the duration of its life. The reproductive act may be regarded as the culminating act of the organism, requiring the highest degree of vitality, and involving the largest expenditure of energy. This act will therefore be performed when the organism has reached maturity; in some cases the animal reaches maturity late, in other cases early; but in all the epoch of maturity may be taken as about a fifth part of the whole duration of life. Thus the elephant and the human being do not reach maturity till say the twentieth year, and the period of longevity is about a hundred years; the horse, ass, and bull are mature in the third or fourth year, and live from fifteen to twenty years, sheep come to maturity in the second year, and live from eight to ten years; whilst rabbits and guinea pigs are mature within one year, and live only from four to five years. Here again there are exceptions, as, for example, the cat is mature before the end of the first year, and still it may live to the age of twenty years. Much information is still required on these points before a law can be formulated.

The question of longevity, however, probably presents the greatest interest in its relation to man. It is still a popular belief that the earliest inhabitants of the world possessed an incredible strength, were of an enormous size, and lived to a very great age; and the ages of the patriarchs before the flood are often taken literally, although the conditions making such long lives possible are at variance with those of human existence at the present day. In ancient history there are instances given of heroes who attained the age of several hundred years, but these must be regarded as mythical. For an interesting account of these, see Huxford's *Art of Prolonging Life*, p. 62 *sq.*

The following are a few instances of extreme longevity which have been placed on record:—Margaret Paton, 137; the countess of Desmond, 145; Thomas Parr, 152; Thomas Damme, 154; John Rowin, 173; and Peter Torton, 185. There can be little doubt that the ages of these persons have been much exaggerated. They lived at a time when no accurate chronological records were kept, and when it was the habit to fix the dates of occurrences by comparing them in the memory with other events believed to have happened about the same time. Thus

there were many sources of fallacy, although the narrators no doubt believed their statements to be quite accurate. Still these were instances of prolongation of human life far beyond the usual limits, and there is no reason for doubting that they all lived till they were upwards of a hundred years of age.

Perhaps the best authenticated instance of this kind is that of the famous Thomas Parr of Shropshire. "He was a poor farmer's servant, and obliged to maintain himself by daily labour. When above one hundred and twenty years of age he married a widow for his second wife, who lived with him twelve years, and who asserted that during that time he never betrayed any signs of infirmity of age. Till his one hundred and thirtieth year he performed all his usual work, and was accustomed even to thresh. Some years before his death his eyes and memory began to fail, but his hearing and senses continued sound to the last. In his one hundred and fifty-second year his fame had reached London, and, as the king was desirous of seeing so great a rarity, he was induced to take a journey thither. Thus, in all probability, shortened his existence, which he otherwise might have protracted some years longer, for he was treated at court in no royal a manner, and his mode of living was so totally changed that he died soon after, at London, in 1685. He was one hundred and fifty-two years and nine months old, and had lived under nine kings of England. What was most remarkable in regard to this man is that, when his body was opened by Dr Harvey (the discoverer of the circulation of the blood), his internal organs were found to be in the most perfect state, nor was the least symptom of decay to be discovered in them. His cartilages even were not ossified, as is the case in all old people. The smallest cause of death had not yet settled in his body; and he died merely of a plethoria, because he had been too well treated."—Huxford, p. 71.

The late Sir George Cornewall Lewis attempted to show that all such narratives were so inaccurate as to reduce the ages of the persons to something under a hundred years, and he was disposed to think that there had been no instance of a human being attaining the age of a hundred years. But subsequent cases have shown that a few have attained that great age. In these cases the evidence has not been of a collateral kind, nor has it depended on human memory, but it has been established by written records. Scarcely a year passes without instances occurring in which the evidence that the deceased attained a hundred years cannot be controverted, and there is no doubt that, when a sufficient time from the beginning of the system of registration of births has elapsed, such cases will be more common.

The average duration of life in Europe is about thirty-four years. It oscillates between 28-18 years (Prussia) and 39-8 years (Schleswig-Holstein, Lauenburg). In Naples it is quoted at 31-65 years. This falls far short of the possible longevity, a circumstance chiefly to be accounted for by the great mortality in the early years of life. According to De Quatrefages, the duration of life is almost universally the same amongst the best known peoples. Lepers live to a great age, men of from seventy to ninety years of age being common among them. The American Indians have apparently as long a life, on the average, as the white man living in the same locality. It would appear to be the same in the case of the negro. Prichard quotes from an official document of the State of New Jersey, showing that the census gave one negro centenarian in the 1000, but only one white centenarian in 150,000, on the other hand, the negro of the Senegal ages early, and does not live long. In his native place he is exposed to unhealthy influences which tell upon him, although he resists the bad effects of these longer and better than the white man; but when he is transplanted to America he enjoys a longer life.

The manner of life and nature of the occupation, apart from hereditary and special causes, have a most important influence on the duration of life. Few emperors or kings have attained the age of eighty; and, of more than three hundred popes, only six have exceeded the age of eighty. It

would seem that brain work is not unfavourable to longevity. It is almost proverbial that statesmen and judges often reach an advanced age. Many men famous in literature and science have lived to an old age. Thus from fifty to sixty we have Tasso, Virgil, Shakespeare, Molière, Dante, Pope, Ovid, Horace, Racine, Montesquieu; from sixty to seventy, Lavater, Galvani, Boccaccio, Fenelon, Aristotle, Cuvier, Milton, Rousseau, Erasmus, Cervantes, from seventy to eighty, Dryden, Potnam, Linnaeus, Locke, Handel, Galileo, Swift, Roger Bacon, Charles Darwin; from eighty to ninety, Thomas Carlyle, Young, Plato, Buffon, Goethe, Franklin, Sir W. Herschel, Newton, Voltaire, Haller; and from ninety to one hundred, Sophocles, Leuwenhoek, Michelangelo, Titian. Physicians are often long lived. Boerhaave, Haller, Gall, Darwin, Van Swieten, Fallopius, Jenner, Cullen, Galen, and Spallanzani died between seventy and eighty years of age, and Harvey, Duhamel, Pamel, Morgagni, Heberden, and Ruych between eighty and ninety; whilst the father of medicine, Hippocrates, is credited with one hundred and nine years.

A valuable set of statistics have been collected by Hirt (*Die Krankheiten der Arbeiter*) regarding the influence of trades on longevity. An abstract of these will be found in Buck's *Hygiene and Public Health*, vol. ii. pp. 71, 72.

The best indication of longevity in a community is given by the expectation of life from any given age. It is obtained by adding together the number of years which the entire population live from any specified age, and dividing the resulting total "years of life" by the number living at the year of age for which the expectation of life is desired (*English Life Table*, p. xxxii). Thus we may find the duration of the portion of human life which an individual at any age may expect to enjoy. Such calculations are of great value in connexion with assurance, and indeed in all pecuniary transactions in which the value of life contingencies are taken into account. They are the bases of all systems of life assurance. Life assurance companies have now been able to collect sufficient numbers of cases of their own experience on which to find trustworthy calculations showing the expectation of life at different ages. Such tables have really been compiled from selected cases, namely, from those who have assured, and consequently differ somewhat from those compiled on the broader data obtained from the whole population. The following table, derived from both sources of information, is given briefly to indicate the expectation of life, or the longevity, from various ages, reference being made for details to the article *INSURANCE*. The table to be read thus: a person at thirty years of age has an average expectation of living 33·3 years longer, or of attaining the age of 63·3 years.

Ages.	England and Wales, Jan. 1, 1851-54	Combined Experience of 17 English Offices, 1843	Ages.	England and Wales, Farr, 1858-64	Combined Experience of 17 English Offices, 1843
0	40·9	—	30	13·9	13·77
10	47·4	48·36	70	8·7	8·64
20	39·9	41·49	80	5·1	4·78
30	33·3	34·43	90	2·9	2·11
40	28·7	27·28	95	2·2	1·28
50	20·1	20·18			

What are the physiological conditions in the human being that determine longevity? In the first place, there is the influence of heredity. Certain peculiarities of tissue are transmitted from parent to offspring that determine whether or not the tissue will remain for a lengthened period of time in a normal condition, or whether it will quickly yield to external influences and take on an abnormal action. As the life of the body is really the sum of the lives of its constituent parts, or in other words,

of the cellular elements composing it, it is evident that anything affecting the healthy action of these elements will affect the life of the body as a whole. In some individuals the tissues have what may be termed a hereditary taint, by which is meant a want of stability, so that they pass readily from a normal into an abnormal condition, and this is unfavourable to longevity.

In the next place, even healthy tissues capable of resisting ordinary influences may be unable to resist long-continued unfavourable conditions. In course of time slow changes begin in the tissue; these in turn affect the organ in which the tissue exists, and the organ, by improperly performing its functions, injures the organism. Thus it is that habitually breathing an impure atmosphere, eating improper food, saturating the body with drugs or with alcohol, over-exerting the nervous system by excitement or prolonged brain-work or worry, and sexual excesses debilitate the body by working slow but sure changes in the tissues which will inevitably tell upon the longevity of the individual.

But even in the most favourable conditions there seems to be a limitation to the healthy action of tissues, and old age comes on. Whether this is or is not the result of long hereditary transmission it is not of much practical importance to ask, as it is a state of things all flesh is heir to. But, if it be hereditary, as is highly probable, there is the satisfaction of knowing that hereditary states can be slowly influenced by individuals living in the best possible conditions and transmitting the influences of good moral and physical hygiene. If bad hereditary qualities are transmitted, good qualities have even a better chance of being perpetuated, as they favour the individual in the struggle for existence. Thus a race which has a low degree of longevity may acquire, by persistent attempts to live in the best conditions, a long average duration of life. This is also true, though to a less extent, of an individual life.

Each tissue has a life of its own; it is developed, reaches maturity, declines, and dies. It may be replaced by successive generations of similar tissues, but the power of reproduction of tissue becomes weakened, and by slow degrees the tissue may disappear, or it may become so altered as to be quite unlike what it was at first. By these tissue-changes functional changes of great importance to the body are brought about. Thus, as age comes on, the blood becomes poorer; respiration is less active; the vital capacity of the chest, that is the working-quantity of air, is diminished; the temperature of the body is slightly increased, so that the aged are more sensitive to cold; the digestive organs are less vigorous; the walls of the arteries become hardened by earthy matter, and lose their elasticity; the veins become dilated, and the circulation is not efficiently performed; the teeth decay and disappear; the cartilages become calcified and hard; the skin is shrivelled and dry, and cutaneous respiration and excretion are less perfect; the hair whitens or falls off; the stature and the weight diminish. By and by muscular movements are less energetic and less precise; the hands tremble and the head shakes; and there is a tottering gait. The cartilages of the larynx ossify, the vocal cords lose their elasticity, and the voice becomes a shrill treble. Then the involuntary muscular tissues are affected so that the bladder is less powerful and defecation is feeble. The transparent media of the eye become dimmed, the near point of vision is pushed back so that the old man becomes presbyopic, or far-sighted, and the power of accommodation, or focussing of the eye, is entirely lost; the delicate mechanism of the drum and bones of the ear is impaired, so that deafness results; and even touch becomes less delicate. Slowly the intellectual faculties become weakened, the emotions are blunted, and the memory becomes by degrees less

trustworthy, and at last vanishes. Much of the time is now spent in sleep, and unless some intercurrent disease snags the thread of life there is a slow ebbing of existence into natural death. Essentially these phenomena are due to delicate changes in the tissues, visible only with the aid of the microscope. These changes are those of wasting or atrophy, meaning a failure of nutrition, or fatty changes, or those caused by infiltration into the tissue of earthy matter, which soon destroys its healthy functions.

HENRY WADSWORTH LONGFELLOW.

Copyright, 1882, by Thomas Davidson

HENRY WADSWORTH LONGFELLOW, (1807-1882), the best known of American poets, was born on the 27th February 1807, at Portland, now the capital of the State of Maine, to which his ancestor, William Longfellow, immigrated, in 1678, from English Hampshire. His father was Stephen Longfellow, a lawyer and United States congressman, and his mother, Zolpha Wadsworth, a descendant of John Alden and of "Precilla, the Puritan maiden."

Longfellow's external life presents little that is of stirring interest. It is the life of a modest, deep-hearted gentleman, whose highest ambition was to be a perfect man, and, through sympathy and love, to help others to be the same. His boyhood was spent mostly in his native town, which he never ceased to love, and whose beautiful surroundings and quiet, pure life he has described in his poem "My Lost Youth." Here he grew up in the midst of majestic peace, which was but once broken, and that by an event which made a deep impression on him—the war of 1812. He never forgot

"the sea-fight far away,
How it thundered o'er the tide,
And the dead captains as they lay
In their graves overlooking the tranquil bay,
Where they in battle died."

The "tranquil bay" is Casco Bay, one of the most beautiful in the world, studded with bold, green islands, well fitted to be the Hesperides of a poet's boyish dreams. At the early age of fourteen Longfellow entered Bowdoin College at Brunswick, a town situated near the romantic falls of the Androscoggin river, about 25 miles from Portland, and in a region full of Indian scenery and legend. Here he had among his classmates Nathaniel Hawthorne, George B. Cheever, and J. S. C. Abbott. During the latter years of his college life he contributed to the *United States Literary Gazette* some half-dozen poems, which are interesting for two reasons—(1) as showing the poet's early, book-mediated sympathy with nature and legendary heroisms, and (2) as being almost entirely free from that supernatural view of nature which his subsequent residence in Europe imparted to him. He graduated in 1825, at the age of eighteen, with honours, among others that of writing the "class poem." After graduation, he remained for a short time at Bowdoin College in the capacity of tutor, and then entered his father's law office, intending, it may be presumed, to devote himself to the study of the law. For this profession he was, both by capacity and tastes, utterly unfitted, and it was fortunate that, shortly after, he received an offer of a professorship of modern languages in his alma mater. In order the better to qualify himself for this appointment, he came to Europe and spent three years and a half travelling in

France, Italy, Spain, Germany, Holland, and England, learning languages, for which he had unusual talent, and drinking in the spirit of the history and life of these countries. For an American, while still in a plastic state, to spend much time in Europe is a doubtful and, not unfrequently, a disastrous experiment, unfitting him for a useful, contented life in his own country. The effect of Longfellow's visit was twofold. On the one hand, it widened his sympathies, gave him confidence in himself, and supplied him with many poetical themes; on the other, it traditionalized his mind, coloured for him the pure light of nature, and rendered him in some measure unfit to feel or express the spirit of American nature and life. His sojourn in Europe fell exactly in the time when, in England, the reaction against the sentimental atheism of Shelley, the pagan sensitivity of Keats, and the sublime, Satanic outcastness of Byron was at its height, when, in the Catholic countries, the negative exaggerations of the French Revolution were inducing a counter current of positive faith, which threw men into the arms of a half-sentimental half-aesthetic mediævalism; and when, in Germany, the aristocratic paganism of Goethe was being swept aside by that tide of dutiful, romantic patriotism which flooded the country, as soon as it began to feel that it still existed after being run over by Napoleon's war-chariot. When, in 1829, he returned to assume his duties at Bowdoin College, he saw the world and man no longer in the clear effulgence of nature, but in the subdued and tinted light that comes through painted cathedral window, or in the reflected rays that fall from scintillating moons. He remained six years at Bowdoin College. In his twenty-fourth year (1831) he married Miss Mary S. Potter, one of his "early loves," and in 1833 published, first, a small volume of translations from the Spanish, with an introductory essay on the moral and devotional poetry of Spain, and then part of *Under the Allee*, a youthfully brilliant work, for which a fitting title would have been "Poetry and Truth from my Travels." The latter contained some translations from the French, and was completed in 1835.

In 1835 Longfellow was chosen to succeed George Ticknor as professor of modern languages and belles-lettres in Harvard College, Cambridge, Mass., the oldest and most illustrious institution of higher learning in the country. On receiving this appointment, he paid a second visit of some fifteen months to Europe, this time devoting special attention to the Scandinavian countries and Switzerland. During this visit he lost his wife, who died at Rotterdam, November 29, 1835. The poet speaks of her in "Footsteps of Angels" as

"the Being Dearest
Who unto my youth was given,
More than all things else to love me,
And is now a saint in heaven."

On his return to America in 1836, Longfellow took up his residence in Cambridge, and began to lecture and write. In his new home he found himself amid surroundings entirely congenial to him. Indeed, there are few places in the world which a man of learning, refinement, sociability, and liberal views would rather choose for a residence than Cambridge. Its spaciousness and free rural aspect, its old graveyards and towering clime, its great university, its cultivated society, for admission to which unabsorbed wealth is a positive disqualification, and its vicinity to humane, substantial, busy Boston, are all attractions for such a man. In 1837-38 several essays of Longfellow's appeared in the *North American Review*, and in 1839 he published *Hyperion*, and his first volume of original poetry, entitled *Voices of the Night*. The former, a poetical account of his travels, had, at the time of its

publication, an immense popularity, due mainly to its sentimental romanticism. At present few persons beyond their teens would care to read it through, so unnatural and stilted is its language, so thin its material, and so consciously mediated its sentiment. Nevertheless it has a certain historical importance, for two reasons—(1) because it marks that period in Longfellow's career when, though he had left nature, he had not yet found art, and (2) because it opened the sluices through which the flood of German sentimental poetry flowed into the United States—a flood whose waters, after forty years, are not yet assuaged. The *Voices of the Night* contains some of his best minor poems, e.g., "The Psalm of Life" and "Footsteps of Angels." In 1841 Longfellow published a small volume of *Ballads and other Poems*, containing some of his most popular pieces, e.g., "The Skeleton in Armour," "The Wreck of the Hesperus," "The Village Blacksmith," "To a Child," "The Bridge," "Excelsior." In 1842 he paid a third brief visit to Europe, spending the summer on the Rhine. During his return-passage across the Atlantic he wrote his *Poems on Slavery*, which he published the same year, with a dedication to Channing. These poems went far to wake in the youth of New England a sense of the great national wrong, and to prepare them for that bitter struggle in which it was wiped out at the expense of the lives of so many of them. In 1843 he married again, choosing this time Miss Frances E. Appleton of Boston, a daughter of Hon. Nathan Appleton, one of the founders of Lowell, and a sister of Thomas G. Appleton, himself no mean poet.

About the same time he bought, and fixed his residence in, the house in which he had formerly only been a lodger, an old "revolutionary house," built about the beginning of last century, and occupied by General Washington at the time when he took command of the United States army in 1776. This quaint old wooden house, which stands in the midst of a large garden full of splendid elms, continued to be his chief residence till the day of his death. Of the lectures on Dante which he delivered about this time, James Russell Lowell says:—"These lectures, illustrated by admirable translations, are remembered with grateful pleasure by many who were thus led to learn the full significance of the great Christian poet." Indeed, as a professor, Longfellow was eminently successful. Shortly after the *Poems on Slavery*, there appeared in 1843 a more ambitious work, *The Spanish Student*, a kind of sentimental "Morality," without any special merit but good intention. If published nowadays it would hardly attract notice; but in those gushing, emotion-craving times it had considerable popularity, and helped to increase the poet's now rapidly widening fame. A huge collection of translations of foreign poetry edited by him, and entitled *The Poets of Europe*, appeared in 1845, and, about the same time, a few minor poems—songs and sonnets—under the title *The Belfry of Bruges*. In 1847 he gave to the world the greatest of all his works, and the one which will carry his name down to posterity—*Evangeline, a Tale of Acadie*. It was, in some degree, an imitation of Goethe's *Hermann and Dorothea*, and its plot, which was derived from Hawthorne's *American Note-Books*, is even simpler than that of the German poem, not to say much more touching. At the violent removal by the British Government of a colony of French settlers from Acadie (Nova Scotia) in 1755, a young couple, on the very day of their wedding, got separated and carried in different directions, so that they lost all trace of each other. The poem describes the wanderings of the bride in search of her lover, and her final discovery of him as an old man on his death-bed, in a public hospital which she had entered as a nurse. Slight as the story is, it is worked out into

one of the most affecting poems in the language, and gives to literature one of its most perfect types of womanhood and of "affection that hopes and endures and is patient." Though written in a metre deemed foreign to English ears, the poem immediately attained a wide popularity, which it has never lost, and secured to the dactylic hexameter a recognized place among English metres.

In 1849 Longfellow published a novel of no great merit, *Kavanagh*, and also a volume of poems entitled *The Seaside and the Fireside*, a title which has reference to his two homes, the seaside one on the charming peninsula of Nahant, the fireside one in Cambridge. One of the poems in this collection, "Resignation," has taken a permanent place in literature; another, "Hymn for my Brother's Ordination," shows plainly the nature of the poet's Christianity. His brother, the Rev. Samuel Longfellow, is a minister of the Unitarian Church.

Longfellow's genius, in its choice of subjects, always oscillated between America and Europe, between the colonial period of American history and the Middle and Romantic Ages of European feeling. When tired of the broad daylight of American activity, he sought refuge and rest in the dim twilight of mediæval legend and German sentiment. In 1851 appeared *The Golden Legend*, a long lyric drama based upon Hartmann von Aue's beautiful story of self-sacrifice, *Der arme Heinrich*. Next to *Evangeline*, this is at once the best and the most popular of the poet's longer works, and contains many passages of great beauty. Binging his imagination back to America, he next applied himself to the elaboration of an Indian legend. In 1854 he resigned his professorship. In the following year he gave to the world the Indian Edda, *The Song of Hiawatha*, a conscious imitation, both in subject and metre, of the Finnish epic, the *Kalevala*, with which he had become acquainted during his second visit to Europe. The metre is monotonous and easily ridiculed, but it suits the subject, and the poem is very popular. In 1858 appeared *The Courtship of Miles Standish*, based on a charming incident in the early history of the Plymouth colony, and, along with it, a number of minor poems, included under the modest title, *Birds of Passage*. One of these is "My Lost Youth."

Two events now occurred which served to cast a gloom over the poet's life and to interrupt his activity,—the outbreak of the civil war, and the tragic fate of his wife, who, having accidentally allowed her dress to catch fire, was burnt to death in her own house in 1861. It was long before he recovered from the shock caused by this terrible event, and in his subsequent published poems he never ventured even to allude to it. When he did in some measure find himself again, he gave to the world his charming *Tales of a Wayside Inn* (1863), and then a "second flight" of his *Birds of Passage*. Among the latter is a poem entitled "The Children's Hour," which affords a glance into the home life of the widowed poet, who had been left with five children—two sons, Ernest and Charles, and three daughters,

"Grave Alice, and laughing Allegra,
And Edith with golden hair."

The *Birds of Passage* was succeeded by a small volume entitled *Flower de Luze* (1868), which contains, among other fine things, the beautiful "threnos" on the burial of Hawthorne, and "The Bells of Lynn." Once more the poet sought refuge in mediæval life by completing his translation of the *Divina Commedia*, parts of which he had rendered into English as much as thirty years before. This work appeared in 1867, and gave a great impulse to the study of Dante in America. It is a masterpiece of literal translation. Next came the *New England Tragedies* (1868), and *The Divine Tragedy* (1871), which found no large

public. In 1868-69 the poet visited Europe, and was everywhere received with the greatest honour. In 1872 appeared *Three Books of Song*, containing translated as well as original pieces, in 1873 *Aftermath*, in 1874 *The Hanging of the Crane*, and in 1875 *The Mask of Pandora*, and other Poems. Among these "other poems" were "The Hanging of the Crane," "Mortuiri Salutamus," and "A Book of Sonnets." *The Mask of Pandora* is a proof of that growing appreciation of pagan naturalism which marked the poet's later years. Though not a great poem, it is full of beautiful passages, many of which point to the riddle of life as yet unsolved, a conviction which grew ever more and more upon the poet, as the bullenness of romanticism gave way to the calm of classic feeling. In the "Book of Sonnets" are some of the finest things he ever wrote, especially the five sonnets entitled "Three Friends of Mine." These "three friends" were Cornelius Felton, Louis Agassiz, and Charles Sumner, whom he calls

"The noble three,
Who half my life were more than friends to me."

The loss of Agassiz was a blow from which he never entirely recovered; and, when Sumner also left him, he wrote—

"Thou hast but taken thy lamp and gone to bed,
I stay a little longer, as one stays
To cover up the embers that still burn."

He did stay a little longer; but the embers that still burnt in him refused to be covered up. He would fain have ceased writing, and used to say, "It's a great thing to know when to stop"; but he could not stop, and did not stop, till the last. He continued to publish from time to time, in the magazines, poems which showed a clearness of vision and a perfection of workmanship such as he never had equalled at any period of his life. Indeed it may be said that his finest poems were his last. Of these a small collection appeared under the title of *Keramos, and other Poems* (1875). Besides these, in the years 1875-78 he edited a collection of *Poems of Places* in thirty-one small volumes. In 1880 appeared *Ultima Thule*, meant to be his last work, and it was nearly so. In October 1881 he wrote a touching sonnet on the death of President Garfield, and in January 1882, when the hand of death was already upon him, his last poem, *Hermes Trismegistus*, in which he gives utterance, in language as rich as that of the early gods, to that strange feeling of awe without fear, and hope without form, with which every man of spotless life and upright intellect withdraws from the phenomena of time to the realities of eternity.

In the last years of his life he suffered a great deal from rheumatism, and was, as he sometimes cheerfully said, "never free from pain." Still he remained as sunny and genial as ever, looking from his Cambridge study windows across the Brighton meadows to the Brookline hills, or enjoying the "free wild winds of the Atlantic," and listening to "The Bells of Lynn" in his Nahant home. He still continued to receive all visitors, and to take occasional runs up to Castine and Portland, the homes of his family. About the beginning of 1882, however, a serious change took place in his condition, and he was obliged to withdraw from the public gaze. Dizziness and want of strength confined him to his room for some time, and, although after some weeks he partially recovered, his elasticity and powers were gone. He now acknowledged the receipt of letters with a printed form. At last the end came. On the 19th March he was seized with violent paroxysms of vomiting and pain, which continued until the 22d, when his mind began to wander. The 23d was passed in a torpid condition, which, though it vanished on the morning of the 24th, returned in the course of the day, and passed, by insensible degrees, into the profound sleep of death.

The poet was buried on the 26th, near his "three friends," in Mount Auburn cemetery. The regret for his loss was universal; for no modern man was ever better loved or better deserved to be loved.

Longfellow was made an LL.D. of Bowdoin College in 1898, at the age of twenty-one, of Harvard in 1859, and of Cambridge (England) in 1868, and D.C.L. of Oxford in 1869. In 1873 he was elected a member of the Russian Academy of Science, and in 1877 of the Spanish Academy.

In person, Longfellow was rather below middle height, broad-shouldered, and well built. His head and face were extremely handsome, his forehead broad and high, his eyes full of clear, warming fire, his nose straight and graceful, his chin and lips rich and full of feeling as those of the Praxitelean Hermes, and his voice low, melodious, and full of tender cadences. His hair, originally dark, became, in his later years, silvery white, and its way locks combined with those of his flowing beard to give him that leonine appearance so familiar through his later portraits. Charles Kingsley said of Longfellow's face that it was the most beautiful human face he had ever seen. And many agreed with him.

In trying to form an estimate of Longfellow, we are not obliged, as in the case of so many other poets, to distinguish the poet from the man, or to degrade the nature of the former by making it an excuse for the failings of the latter. In Longfellow, the poet was the flower and fruit of the man. His nature was essentially poetic, and his life incomparably the greatest of his poems. Those who knew only the poems he wrote could form but a faint notion of the harmony, the sweetness, the manliness, and the tenderness of that which he lived.

Of the two orders of poets distinguished by Aristotle—that of the imitator of plastic, and that of the versifier of abstract—Longfellow belonged distinctly to the latter. Nature did not come to him as to a Pythia seated on a tripod, and fill him with wisdom expressible only in rhythmic prophecy; she did not even call him as a private secretary, and dictate to him her secret messages of love and kindness; justice and watchfulness were his constant attendants. He went to nature, sometimes as the Angel of the Annunciation, revealing to her that she was pregnant with divinity, sometimes as a priest pronouncing a benediction over her. What he would have been as a poet, if, instead of visiting Europe in early life and drinking in the spirit of the Middle Ages, he had been a mystic, a seer, a prophet, that point upwards to a world above nature, and backwards to a time when that world darkened the law of nature, he had, like Whitman, grown old amid the unexamined paganism of American scenery and life, we can only guess from his earlier poems, which are as naturalistic, fresh, and unmythical as could be desired, but certain it is that, from his long familiarity with the medieval view of nature, and its semi-pagan offshoot, the romantic view, he was brought, for the greater part of his life, to look upon the world of men and things either as the middle scene of a miracle play, with a heaven of rewarding happiness above and a purgatory of punishing pain below, or else as a garment concealing, while it revealed, spiritual forms of unfathomable mystery. During this time he could hear "the trailing garments of the night sweep through her marble halls," and see "the stars come out to listen to the music of the oars." Later on, as he approached his second youth (he was spared a second childhood), he tended to a more pagan view. About the time when he was writing *The Mask of Pandora*, he could see "in the sunset Jason's fleece of gold," and hear "the waves of the distracted sea, piteously calling and lamenting" his lost friend. But through all the periods of his life his view of the world was essentially religious and subjective, and, consequently, his manner of dealing with it hymnical or lyric. This fact, even more than his merits as an artist, serves to account for his immense popularity. Too well-informed, too appreciative, and too modest to deem himself the peer of the "grand old masters," or one of "those few stars that come in sight once in a century," he made it his aim to write something that should "make a yonder faith and mankind alive in the untutored heart," and to do this in the way that should best reach that heart. This aim determined at once his choice of subjects and his mode of treating them.

The subjects of Longfellow's poetry are, for the most part, aspects of nature as influencing human feeling, either directly, through historical association, the tender or repulsive side and incidents of life, or heroic deeds preserved in legend or history. He had a special fondness for records of human devotion and self-sacrifice, whether they were monkish legends, Indian tales, Norse *dröms*, or bits of American history. His mode of treatment, as we have already said, is subjective and lyric. No matter what form his works

anyme, whether this epic, as in "Evangeline," "The Courtship of Miles Standish," and "Huwatha," the dramatic, as in "The Spanish Student," "The Golden Legend," and "The Mask of Pandora," or the didactic, as in "The Psalm of Life" and many of the minor poems, they are all subjective. This is not the highest phase that can be given to works of art; but it implies less disservice in Longfellow's case than in almost any other, by reason of his noble subjectivity.

If we look in Longfellow's poetry for originality of thought, profound psychological analysis, or new insights into nature, we shall be disappointed. Though very far from being hampered by any dogmatic philosophical or religious system of the past, his mind, until near the end, found sufficient satisfaction in the Christian view of life to make it indifferent to the restless, inquiring spirit of the present, and disinclined to play with any more recent solution of life's problems. He had no sympathy with either scepticism or formal dogmatism, and no need to hazard rash guesses respecting man's destiny. He was willing to say—

"I do not know, nor will I vainly question
Those pages of the mystic book which hold
The secret still unsold.
But without rash conjecture on speculation
Turn its last leaves in reverence and good heed,
Until 'The End' I read."

He disliked the present psychological school of art, believing it to be essentially nihilist and unhealthy. He had no sympathy with the tendency represented by George Eliot, or with any attempt to be analytic in art. He held art to be essentially synthetic, creative, and unanalyzing, not analytic, destructive, or questioning. Hence he never strove to draw from nature some new secret, or to show us her relations never discovered before. His aim was to impress upon her familiar facts and aspects the seal of his own gracious nature. And in this no one ever succeeded better. "The light of the life of him is on all past things. For his reason, while his poems never reveal to us a new meaning in nature or show us a new spring of hope in man, they make us love both better than we did before. Though he never raised the curtain that hides the stage upon which the physical and moral powers of nature rehearse the drama of human life, yet he opens our eyes to the notes of the orchestra that sets before the stage and plays the overture, and, as we listen to these notes, there before us touching pictures of love, and faith, and devotion, until we find ourselves melted down and simplified into little children, whereof is the kingdom of heaven."

We have said that Longfellow's protracted residence in Europe in some degree unfitted the new life of the American republic; and this is true. He was essentially a poet of the past, not, like Lowell, a gripper and moulder of the present, or like Whitman, a John the Baptist of the future. But, just as Dante summed up the ages of faith, and Shakespeare the ages of fondalism, so Longfellow has summed up the period of transition from these to the ages of truth and liberty—a period in which the killing letter of Christian womanliness and pagan manliness has slowly been yielding to their vivifying spirit, and preparing the way for that simple humanity of which he was the earnest and the type.

As a man, Longfellow was almost perfect, as much so as it is even given to human nature to be. A man in intellect and courage, yet without conceit or bravado, a woman in sensibility and tenderness, yet without shrinking or weakness; a saint in purity of life and devotion of heart, yet without asceticism or religiosity; a knight-errant in hetero, wrong and confusion of business, yet without self-righteousness or cynicism; a prince in dignity and courtesy, yet without formality or condescension; a poet in thought and feeling, yet without jealousy or affectation; a scholar in tastes and habits, yet without aloofness or bookishness; a dutiful son, a loving husband, a judicious father, a trusty friend, a useful citizen, and an enthusiastic patriot—he united in him strong, transparent humanity almost every virtue under heaven. A thoroughly healthy, well-balanced, harmonious nature, accepting life as it came, with all its joys and sorrows, and living it beautifully and hopefully, without canker and without uncharity. No man ever lived more completely in the spirit than Henry Wadsworth Longfellow.

Perhaps the most remarkable traits in Longfellow's character were his accessibility and his charity. Though a great worker, he seemed always to have time for anything he was asked to do. He was never too busy to see a caller, to answer a letter, or to assist, by word or deed, anyone that needed assistance. He was ready to all visitors, even to strangers and children who called to look at him, or who, not venturing to call, hung about his garden-gate in order to catch a glimpse of him, was almost a marvel. He always took it for granted that they had come to see Washington's study, and accordingly, took the greatest interest in showing them that. He never, as long as he could write, was known to refuse his autograph, and so far was he from trying to protect himself from intruders that he rarely drew the blinds of his study windows at night, though that study was on the ground floor and faced the street. His acts of charity, though performed in secret, were neither few nor small. Of him it may be said with perfect truth, "He went about doing good"; and not with his money merely, but also with his presence

and his encouragement. To how many sad hearts did he come like an angel, with the rich tones of his voice waking harmonies of hope, where before there had been despair and silence! How many young literary people, disappointed of the unsuccesses of their first attempts, did he comfort and spur on to renewed and higher efforts! How careful he was to quench no smoking fire! How utterly free he was from jealousy or revengefulness! While poor, modest Edgar Allan Poe was writing violent and scurrilous articles upon him, accusing him of plagiarism and other literary misdemeanours, he was delivering enthusiastic lectures to his classes on Poe's poetry. His charity was unbounded. Once when the present writer proposed to the president of the Harvard University Visiting Committee that Longfellow should be placed on that committee, the president replied: "What would be the use? Longfellow could never be brought to find fault with anybody or anything." And it was true. His whole life was bathed in that sympathy, that love which suffers long and envies not, which forgives unto seventy times seven times, and as many more if need be. Even in his last years, when loss of friends and continual physical pain made life somewhat "cold and dark, and dreary" for him, he never complained, lamented, or blamed the arrangements of nature, and the only way in which it was possible to know that he suffered was through his ever increasing delight in the health and strength of younger men. His whole nature was summed up in the lines of his favourite poet

"Amore intellettuale, pieno d'amore,
Amor di vero ben, non di lusinga,
Lodate che succedete nel dolore."

(T. DA)

LONGFORD, an inland county of Leitrim, Ireland, is bounded on the N.W. by Leitrim, N.E. by Cavan, E. by Westmeath, S. by Westmeath and Meath, and W. by Lough Ree and Roscommon. With the exception of Carlow, Louth, and Dublin, it is the smallest county in Ireland, its greatest length being about 28 miles, its greatest breadth about 20, and the total area comprising 239,409 acres, or about 421 square miles.

The general level surface of the county is broken occasionally by low hills, which cover a considerable area at its northern angle. The principal rivers are the Camlin, which rises near Grunard, and flows past Longford to the Shannon, and the Inny, which, entering the county from Westmeath, crosses its southern corner, and falls into Lough Ree. Lough Ree is partly included in Longford, and the other principal lakes are Lough Gownagh, Derrylough, Lough Dumm, and Lough Bannow. The Royal canal intersects the county. The southern division of the county, bounded partly by the Camlin, belongs to the great limestone plain of Ireland, and the northern division is occupied chiefly by clay-slate and greywacke. In the west of the county there is an interpolation, between the two divisions, of yellow sandstone and conglomerate. Isolated hills of sandstone occur at Slievegandry and at Ballymahon, on both sides of the Inny. Marble of fine quality has been raised near Ledwithstown. In the north indications of iron are abundant, and there are also some traces of lead.

Agriculture.—The climate is somewhat moist and cold, partly owing to the large extent of marsh and bog. The soil in the southern districts resting on the limestone is a deep loam well adapted for pasture, but in the north it is often so thin and poor as to be incapable of reclamation.

In 1881 there were 74,876 acres under tillage, 125,838 pasture, 3697 plantation, and 61,333 waste. The total number of holdings in 1880 was 2682, of which 985 were less than 1 acre. More than one-half of the total number were included in those between 5 and 16, and 16 and 30 acres in extent, which numbered respectively 2482 and 2658. The following table shows the areas under the principal crops in 1880 and in 1881:—

Wheat.	Other Cereals.	Potatoes.	Turnips.	Other Green Crops.	Flax.	Meadow and Clover.	Total.
1880	2,513	38,841	828	15,268	2,701	666	58,166
1881	2,507	37,570	583	15,168	2,700	918	57,936

The total number of horses in 1881 was 6886, of which 4265 were used for agricultural purposes; of cattle 51,847, of which 10,212 were milch cows; of sheep, 24,140; of pigs, 17,900; and of poultry, 292,824. These were valued at 674,000. According to the latest return, the land was divided among 493 proprietors possess-

ing 256,608 acres, with an annual rateable value of £161,789, the average rateable value per acre being 11s. 1d. The average was 58s. 8d. acre, and 14 per cent. possessed less than 1 acre. The largest owners were Colonel King Harman, 28,779 acres, earl of Granard, 14,678, Lord Annulla, 15,161, George Masonochy, 10,319.

Manufactures.—These are confined almost entirely to coarse woollen and linen cloth.

Railways.—One branch of the Midland Great Western Railway skirts the eastern boundary of the county, and another passes through its centre to Longford.

Administration and Population.—The county includes 6 baronies, with 26 parishes and 801 townlands. It is in the north-west circuit. Assizes are held at Longford, and quarter sessions at Ballynashon, Granard, and Longford. There is one poor-law union wholly within the county, with portions of other two. It is in the Dublin military district and Burr subdistrict. There are barracks for infantry and cavalry at Longford. The county returns two members to parliament.

The only town of any importance in the county town, Longford. From 25,142 in 1780 the population of the county gradually increased till in 1841 it was 116,491, but since then it has diminished to 82,348 in 1851, 64,501 in 1871, and 61,009 in 1881, of whom 30,770 were males and 30,239 females. From 1st May 1881 to 31st December 1881 the number of immigrants was 49,728. For the ten years 1871–81 the marriage-rate per 100 of the population was 4, the birth-rate 24.8, and the death-rate 16. In 1881 23.1 per cent. of the population above five years of age were illiterate, the percentage in 1871 being 32. The Roman Catholics formed 91 per cent. of the population in 1881, and the Episcopalian 8.

History and Antiquities.—The early name of Longford was Analló or Anall, and it was a principality of the O'Farrells. Along with the province of Meath, in which it was then included, it was given by Henry II. to Hugh de Lacy, who planted in it an English colony. On the division of Meath into two counties in 1543, Annulla was included in West Meath, but in the 17th of Elizabeth it was made share ground under the name of Longford, and included in the province of Connaught from which it was transferred to Leinster in the 27th of the same reign.

The principal antiquarian ruin is the Danish rath called the Mot of Granard, at the end of the main street of the town, and occupying a position 598 feet above sea-level. There are monastic remains at Ardagh, Longford, Moyish, Clone, Deig, Dunsinnet, and Kilmonee, as well as on several of the islands of Lough Ree. The principal old castles are those of Rathenee near Lanesborough, and Ballymahon, Burnagee, and Ceshcor on the Lary. The principal modern seats are those of Castlekeech on the Camlin, and Castle Forbes, the seat of the earl of Granard. Oliver Goldsmith was born at Pallas, a village near Ballynashon, in this county.

LONGFORD, the chief town of the above county, is situated on the river Camlin, and on a branch of the Midland Great Western Railway, 75 miles west-north-west of Dublin. The principal buildings are the parish church in the Grecian style, St. Mell's Roman Catholic cathedral (one of the finest Roman Catholic churches in Ireland), the court-house, the market-house, and the county jail. Of the old castle and of the Dominican abbey there are slight remains. The town has a considerable trade in grain, butter, and bacon. There are corn-mills, a spool factory, and tanneries. The population in 1871 was 4376, and in 1881 it was 4380.

The ancient name of the town was *Athfada*, and it is said to occupy the site of a monastery founded by St. Idus, a disciple of St. Patrick. The town obtained a fair and market from James I., and a charter of incorporation from Charles II., as well as the right to return two members to parliament. It was disfranchised at the Union.

LONGINUS, a philosophical critic of great eminence, and one of the brightest spirits of antiquity, uniting Greek subtlety with Roman fervour, flourished in the 3d century, and is known to have perished under sentence of the emperor Aurelian in 273 A.D. He forms one of the last brilliant cluster of pagan literati; and Porphyry, round whom it centred, was the pupil of Longinus. As Porphyry is known to have been born in 233, it is probable that his preceptor, who could not have been less than twenty years his senior, may have been born about 210 A.D. The main authority for the facts of his life is a notice in Suidas, where we find it stated in a preface to a list of his writings that "Longinus Cassius, philosopher, preceptor of Porphyry the philosopher, a learned scholar and critic, lived in the time of the emperor Aurelian, and was cut off by him as

having conspired with Zenobia, the wife of Odenathus." From the same authority we learn that Phronto, the rhetorician of Emesa in Syria, was his uncle, and that Phrontonius, sister of Phronto, was mother to Longinus, who thus became heir to his uncle Phronto. As to his birthplace there is no tradition, but it is probable that he was a native of Syria, possibly of Emesa, to which he undoubtedly belonged. He tells us, as we learn from fragments of his works, that he enjoyed great advantages in travel and education, that his parents, being rich, took him to travel and he saw much of the world, and that he studied at Athens under Phronto, at Alexandria under Ammonius Saccas and the pagan Origenes, and at Rome under Plotinus and Amelius. The Neo-Platonic philosophy was then in the ascendant, but Longinus did not embrace the new speculations which Plotinus was then developing, and continued a Platonist of the old type. Hence the sting of a sarcasm attributed to Plotinus—"Longinus may be a philologist, but he is no philosopher." Longinus did not appear to have reciprocated the sarcastic feeling, for we have still extant a fragment of a letter in which he asks Porphyry to come to Phoenicia and to bring with him the treatises of Plotinus, for, he observes, though he does not feel much attraction for the subjects, he yet likes the man. The reputation which Longinus acquired by his learning was immense; it was of him that Euphrasius first used the expression that has since become proverbial—"living library"—in modern phrase, a walking encyclopædia.

The most conspicuous event of his life was also the most tragic in its consequences. He became secretary to Zenobia, the widowed queen of Palmyra, who, apart from him a knowledge of Greek, and made him her chief counsellor in state affairs. In this capacity he favoured the policy by which she aimed at independence of the Roman empire, encouraged, doubtless, to do so by the recent fate of Valerian, and by the feebleness of the tenure by which Rome held the Syrian provinces. Antioch, however, crushed the pretension, and, while Zenobia lost her power and was, led captive to Rome, Longinus paid the forfeit of his life. According to Zosimus, Zenobia sought to exculpate herself with Aurelian by laying the whole blame on her adviser. He died bravely, not seeking to escape his fate by suicide as a Stoic might have done, but following the example of Socrates and the precept of Plato, to whose philosophy he adhered.¹

The remains of Longinus that have come down to us, unfortunately scanty, are partly fragments of letters, and extracts from criticisms on points of diction; and they bear out the impression we derive from the historical notices of the man. He is vivid and yet minute, lively and penetrating, and his observations show taste, learning, and judgment. Among the most notable of the fragments we have a defence of the Platonic doctrine of the soul as a distinct essence from the body, which defines clearly his philosophical position.

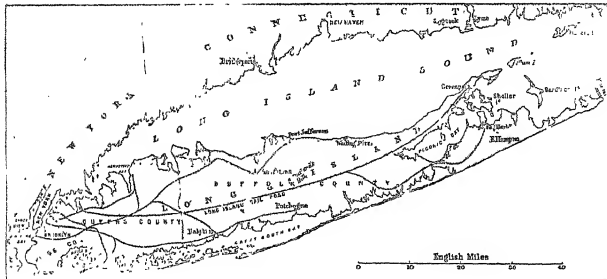

It only remains to advert in a few words to the remarkable production called the *Treatise on the Sublime*, which has usually passed current as a work of Longinus. This remarkable work, which is among the most notable productions of ancient criticism, second only in importance to the *Poetics* of Aristotle, and superior to that work in luminous tenacity and sense of form, cannot be with certainty ascribed to Longinus, although the internal evidence favours the usual ascription. Of the two most startling difficulties the first is the absence of any mention of a treatise *peri hypous* in the list by Suidas. The enumeration is, however, incomplete, and the phrase "many other works," with which it closes, may be held to cover much. A more formidable difficulty is the circumstance that in the most important

¹ It is probable that he owed part of his political fervour to the influence or inheritance of the name "Cassius," from whatever source this surname was derived. The associations of this name were distinctly anti-imperial and even regalistic, as seen in Caius Cassius and in Cassius Cherea.

names up (that is the Paris Catalog, No 2936, of the 10th century) the heading is *Ancientia & Arriphe* giving thus an alternative author "Dionysius," and in the other important MS., the Laurentian of Florence, the title is *Ancientia*, implying that the author was unknown. According to Vandel (*Rhodes*, p. 134) this title is not the original one, and there are traces of an earlier title *Arriphe*, which had formed the superscription. Full information as to the origin of question will be found in the editions of A. E. Egger (*Laurentia quæ superscribitur*, Paris, 1877), Vandel's *Diachronologie* (*Texte de l'histoire de son livre de Rhodes de Longue*, Geneva, 1864), and Otto J. Müller's *Ancientia & Arriphe quæ superscribitur de Solimutella* (*Leipzig*, Bonn, 1862). Vandel ascribes the treatise to Phylarchus, but the evidence negates that supposition, and, although there are difficulties in ascribing the work absolutely to Longinus, as Bodæus did, and even the critics of last century traditionally assumed, there is no other name than that of Longinus that presents so many convincing coincidences, to justify provisionally the current ascription. The fragments that remain of the undoubted works of Longinus are largely characterized by the same lively force and epigrammatic force, which distinguish the treatise, "On the Sublime." The translations of this treatise into all the European languages have been almost infinite, including the famous one by E. de la Motte, who translated the work the favourite vehicle of the belles-lettres to come in the 18th century. The most important English translations are by William Smith, 1759, frequently reprinted, H. D. La Motte, 1840, and by W. D. G.

LONG ISLAND, an island with an area of 1682 square miles lying off the coast of the United States, between

40° 33' and 41° 10' N lat, and forming part of the State of New York. While the length from east to west is about 120 miles, the width nowhere exceeds 24 miles, and in some places falls to 13 or 15. The western end is separated from the city and State of New York by the East River, which is nowhere more than three quarters of a mile in breadth, and has been spanned by a great suspension bridge, but between the main body of the island and the mainland (Connecticut, Rhode Island) lies Long Island Sound, widening out to a breadth of 20 miles. The sound, however, is comparatively shallow, the depth in the eastern and seaward portion being usually under 200 feet, while in the portion west of Connecticut river it is nowhere more than 170 feet, and in general only 75-100 feet. Geologically the island is very interesting, consisting, as it does for the most part, of an immense moraine deposit of glacial drift. A range of hills extends with some interruptions for about 60 miles in the line of its longer axis, varying in height from 150 to 381 feet above sea-level. Fort Pond Hill for instance is 194 feet, Neapeague, 135, Annagisset, 161, Shinnecock, 140, Osborn's Hill, near Riverhead, 293, Highland's south of Coram, 310, West Hills (Jama's Hill), 354, Lloyton's Hill, 380, Westbury, 260, Hempstead

Map of Long Island

Harbour Hill, 384; John M. Clarke's Hill, 326. From the foot of the hills southward stretches a vast newly level plain, with an average height of 70 feet, and consisting of post-glacial stratified sand and gravel, and across this run a large number of shallow parallel watercourses, remarkable mainly for the regularity with which they present an elevated bank on the western side and a long declivity on the eastern. On the northern side of the range the surface is very uneven, some of the elevations exceeding 200 feet, and deep broad valleys stretching down to the sound, and forming a series of excellent harbours. The glacial drift of Long Island is of immense depth, and contains a wonderful number of boulders. "At the eastern extremity," says Lyell on the authority of Mather, "they are of such kinds of granite, gneiss, mica, slate, greenstone, and syenite as may have come across the sound from parts of Rhode Island. Opposite the mouth of the Connecticut river they are of such varieties of gneiss and hornblende slate as correspond with the rocks of the region through which that river passes. Still further west they consist of red sandstone and conglomerate and the trap of that country, and lastly, adjoining the city of New York, we find serpentine, red sandstone, and various granitic and crystalline rocks

which have come from the district immediately to the north." One of the boulders near Mather's measures 54 feet long and 40 feet wide, and lies 16 feet above the level of the soil. Of the numerous boulders scattered throughout Long Island it is enough to mention Ronkonkoma, near Lakeland, the waters of which are said to decrease and increase in regular periods of four years. Much of the surface of the country is still covered with wood—oak, hickory, and chestnut growing freely on the unmodified drift, and pine forests extending for about fifty miles through the sandy plains. A good rich loam abounds in the northern districts, and the lighter soils of the south are easily rendered productive. Market-gardening especially is carried on with success. The climate is comparatively mild, the mean annual temperature being 49° to 51°, the maximum for the year between 95° and 100°, and the minimum 4° to 8°. The average rainfall is about 42.1 inches. Towards its western and more especially the northern coast of Long Island presents a number of important bays—Glen Cove, Oyster Bay, Huntington Bay, Smithtown Bay, &c.; the western extremity is deeply bifurcated by a very irregular inlet, broken up by various islands into Gardiner's Bay, Little Peconic, and Great

Peconic, and along a large part of the southern coast stretches a remarkable series of lagoons, formed by a line of dunes varying in breadth from 1 to 1 mile, and connected at various points with the ocean. Those last—of which the most important is Great South Bay, 40 miles long by about 5 or 6 miles wide—are of great service to the island, and an Act has been passed to increase their utility by connecting them by canals. Coney Island and Rockaway Beach, the most frequented of the many seaside resorts in the island, lie near the south-western extremity. As regards both birds and fishes, Long Island seems a kind of meeting place between the arctic and the equatorial species. In winter, for instance, it is visited by the eider-duck, the little white geese, the great osprey, and the ank, in summer by the turkey buzzard, the swallow-tailed kite, and the fork-tailed flycatcher. A few deer are still to be found; and various tracts of country and islands in the great bays are stocked with game and fish by sportsmen's clubs. The east portion of the island is one of the chief seats of the menhaden fisheries, and the oyster beds of both the north and the south coast are of great value. Those of the Great South Bay (furnishing, amongst others, the famous "blue points") alone give employment in the season to 1500 fishermen. (See E. Ingersoll, "The Oyster Industry," in the *Tenth Census* publications of the United States, 1881.)

Administratively Long Island consists of King's County (72 square miles), Queen's County (410), and Suffolk (1300), which in 1880 had the following population—

	Total	Males	Females	Native	Foreign	White	Coloured
King's ...	289,649	149,289	140,360	411,295	168,324	500,278	6,271
Queen's ...	208,647	104,700	103,947	68,056	21,931	86,707	5,840
Suffolk ...	46,938	23,760	23,178	25,510	5,428	31,477	2,455

Of the thirteen or fourteen Indian tribes living on the island at the time of the discovery, the only remnants are about fifty Shinnecocks and Montauks.

Besides Brooklyn, which had 666,680 inhabitants, King's County contains Flatbush town, 7834; Flatlands town, 3127; Gravesend town (including Coney Island village), 8576; New Lots town, 18,581; and New Utrecht town, 4742. In Queen's county are Flushing town, 16,919; Hempstead town (including East Rockaway, Garden City, and sixteen other villages), 18,160; Jamaica town, 10,089; Long Island City, 17,129; Newtown town, 9798; North Hempstead town, 7562; and Oyster Bay town, 11,928. In Suffolk there are no cities, and none of the villages have 500 inhabitants. The "towns" are Babylon, Brookhaven, East Hampton, Huntington, Illy, Riverhead, Shelter Island, Smithtown, Southampton, and Southold. Garden City was built by A. T. Stewart as a model suburban settlement, and contains a fine cathedral. Hicksville is associated with the memory of Elias Hicks the Quaker missionary. Sag Harbor was formerly a great whaling station, and still maintains a good coasting trade. Five miles from Flushing is Greenvale rifle range, the finest in the United States. On Gardner's Island the pirate Kidd concealed the treasures partly recovered by the governor of Massachusetts in 1699.

Long Island was so called by its Dutch discoverers in 1609, and the name Nassau, bestowed in 1683 by the colonial legislature, never found popular acceptance. Breucklen (Brooklyn), Amersfoort (Flatlands), Vlissingen (Flushing), Rensselaer (Jamaica), and New Utrecht were founded by the Dutch between 1630 and 1664; and between 1640 and 1660 the English from the New England colonies established Southold, Southampton, Southampton, Hempstead, Huntington, Oyster Bay, Smithtown, Illy, &c. Though the charter granted by James I. in 1620 expressly excluded territory actually possessed or inhabited by any other Christian prince or state, the grantees in 1686 conveyed to the earl of Stirling among other lands the island of Matinecock or Long Island. A treaty concluded between Dutch and English at Hartford (Connecticut) in 1650 surrendered to England all the land south of Oyster Bay; but, though it was ratified by the states-general of Holland in 1656, no action was taken by the English Government. Long Island was included in the territory assigned to the duke of York in 1683-84, and in 1684 an English squadron conquered the Dutch in time of peace, and set up a government in the duke's name. When the Dutch governor, who had recovered New York in 1673, issued a proclamation requiring the submission of the Long Island towns, they all obeyed except the three most eastern; but the treaty of Westminster in 1714 left Long Island to the English, and it became a regular colony of the crown. In the beginning of the

war of American independence, Long Island actually played a prominent part. The efforts made by Washington to defend it were frustrated by the British under Cornwallis in 1776, and it remained in their hands till the close of the contest.

LONG ISLAND CITY, a city of the United States, the capital of Queen's County, New York, situated on the west coast of Long Island, and separated from New York by the East River and from Brooklyn by the Newtown Creek. The area, which includes what were the past villages of Astoria, Newtown, and Ravenswood, measures 3 miles from east to west and 5 miles from north to south, and the general plan of the place is constructed on a spacious scale. The river frontage extends to about 10 miles. Hunter's Point, as the south-west portion is called, contains the terminal depôts of several railway lines, extensive warehouses for the storage of petroleum, and a variety of industrial establishments—such as granite-works, chemical works, engine-works. In the Astoria district there are factories for pianos, carriages, and carpets. Long Island City dates from 1870, in 1871 its population was about 16,000, and in 1880 17,117.

LONGITUDE. See **GEOGRAPHY (MATHEMATICAL)** and **TIME**.

LONGOMONTANUS, or **LONGIBURG**, **CHRISTIAN** (1562-1647), a Danish astronomer, was born at Loughere, a village of Jutland, in Denmark, on the 11th of October 1562. Having, when only eight years old, the misfortune to lose his father, who was only a poor labourer, he was taken charge of by a maternal uncle, through whose influence he received lessons from the clergyman of the place. Although, owing to the poverty of his parents, the instruction which he had received up to this time had been of the most elementary kind, his aptitude for learning was so great that, under the tuition which he now received, he made rapid progress in his studies, especially in the mathematical sciences, for which he acquired an intense liking. His mother, however, was unable to pay any longer for his education, and he was reluctantly compelled to return home to work in the fields. By improving every opportunity which his laborious life now permitted, he was still enabled to pursue, to some extent, his favourite studies. This state of matters continued for some time; but his intense thirst for knowledge, and the unrelieved jealousy of his friends, led him in 1577 to steal away from home, to try his fortune in the world. Accordingly, at the age of fifteen, he went to Wiborg, a town about 12 miles distant from his native village. There he spent eleven years, dividing his time between attending the lectures of the professors in the college of that town, and working in the fields. By this means he was able not only to earn a sufficient livelihood, but also to defray the expenses of his education; and his close application to study soon enabled him to acquire considerable knowledge of literature and of the sciences. In 1588, at the age of twenty-six, he removed to Copenhagen, where his great abilities speedily secured for him the esteem and admiration of the professors in the university of that town. By this means he was brought under the notice of the eminent astronomer Tycho Brahe, who received him very kindly, and ultimately appointed him his assistant. He remained with Tycho Brahe for eight years in the island of Høene, and during that time rendered him such valuable services in his astronomical observations and calculations, that, when Tycho Brahe settled in Germany, he invited Longomontanus to accompany him. This offer he accepted; but having shortly afterwards expressed to Tycho Brahe his desire to return to his native country, the latter at once furnished him, not only with excellent testimonials, but also with money for his journey. On his return to Denmark he made a long detour in order to visit the places whence Copernicus

had made his celebrated astronomical observations. On his arrival at Copenhagen, he found a patron in the person of Christian Friis, chancellor of Denmark, who gave him employment in his household. He continued in this situation till 1603, when he received the appointment of rector of the college of Wiborg. Two years later (1605) he was elected to the chair of mathematics in the university of Copenhagen. This appointment he held till his death, on the 8th of October 1617. Longomontanus, although one of the best astronomers of his age, inherited some of his worst prejudices. A firm believer in astrology, he held, among other things, that comets were messengers of evil. He also imagined that he had squared the circle. He found that the circle whose diameter is 43 has for its circumference the square root of 18253, — which gives 3.14185 for the value of π . Poll and others endeavoured to prove that he was mistaken, but they failed to convince him of his error. He refers to his imagined discovery in almost all his published works, and defends his position with great zeal.

The following is a list of his more important works in mathematics and astronomy, with the dates of their first publication: — *Synopsis Mathematica*, &c. 1611; *Cyclometriae et Logarithmorum de monstrata*, &c. 1612; *Disquisitiones de Logarithmo*, 1616; *Astronomiæ Dialectica*, &c. 1622; *Disquisitiones quatuor Astrologicae*, 1622; *Poetæ præfationibus Philosophicis*, 1623; *De Chronologia Historica, seu de Temporis Dispositione*, &c. 1627; *Geometriae quædam XLII. de Cyclometriae rationibus et versis*, 1631; *Summa Quatuordecim Circuli*, 1634; *Disquisitiones de Arithmetica Indole*, 1636; *Comæ Prædictæ et de Mysteriis tractatus Numerorum*, 1637; *Problematum de Geometria*, 1638; *Problematum cum Pantomatibus de Geometria*, 1638; *Inductio in Theatrum Astronomicum*, 1639; *Quædam in Pantomatibus*, &c. 1641; *Admiranda Operum verum Numerorum*, &c. 7. 8. &c. 1645; *Opus Geometricum seu de Geometria Mysteriis*, &c. 1646.

LONGUEVILLE, ANNE GENEVIEVE, DUCHESS DE (1619-1679), who played the greatest part in the troubles of the Fronde, and whose name has come down to posterity as the brilliant intriguer in politics in her early and the pious protectress of the nuns of Port Royal in her later years, was the only daughter of Henri de Bourbon, Prince de Condé, and his wife Charlotte Marguerite de Montmorency, and the only sister of Louis, the great Condé. She was born on August 28, 1619, in the prison of Vincennes, into which her father had been thrown for opposition to Marshal D'Ancre, the favourite of Marie de' Medici, who was then regent in the minority of Louis XIII. She was educated in the convent of the Carmelites in the Rue St Jacques at Paris, which had been recently established under the influence of St Teresa's reforms by nuns of the strictest piety, whose teaching she never entirely forgot. Her early years were clouded by the execution of the young and brilliant Duc de Montmorency, her mother's only brother, for intriguing against the great Richelieu in 1631, and that of her mother's cousin the Comte de Montmorency Boutteville for dwelling in 1635; but, in spite of their sorrow, her parents made their peace with Richelieu, and when she was introduced into society in 1635 she found plenty of court society to enjoy. She soon became one of the bright particular stars of the Hôtel Rambouillet, where all that was learned, witty, and gay in France used to assemble, and which had not yet degenerated into the meeting place of those *précieuses* whom Molière was to laugh out of existence. It was first proposed to marry her to the young Prince de Joinville, and thus unite the Guises and Condés, but he died in 1639, and her parents could only find for her husband the Duc de Longueville, a prince of the blood indeed, and governor of Normandy, but a widower, and twice her age. The marriage could not be a happy one, but the young duchess long remained faithful to him, and bore him four children. After Richelieu's death her father became chief of the council of regency during the minority of Louis XIV., her brother

Louis won the great victory of Rocroy in 1643 (see CONDÉ), and the duchess became of political importance. In 1647 she accompanied her husband to Münster, where he was sent by Mazarin as chief envoy, and where she charmed the German diplomatists who were making the treaty of Westphalia, and was addressed as the "goddess of peace and concord." On her return she fell in love with the Duc de la Rochefoucauld, the author of the *Maxims*, who made use of her love to obtain influence over her brother, and thus win titles and honours for himself. She was the guiding spirit of the first Fronde, when she brought over Armand, Prince de Conti, her second brother, and her husband to the malcontents, but she failed to attract Condé himself, whose loyalty to the court overthrew the first Fronde. However, La Rochefoucauld won the titles he desired. The second Fronde was again her work, owing to her lover's disgust at losing his new honours, and in it she played the most prominent part in attracting to the rebels first Condé and later Turenne (see CONDÉ). It is not necessary to give the whole history of the wars of the Fronde, which is detailed elsewhere, but it must be noticed that the duchess herself only mingled in politics to please her lover, and gain his ends. In the last year of the war she was accompanied into Guienne by the young and handsome Duc de Nemours, her intimacy with whom gave La Rochefoucauld an excuse for abandoning her, and who himself immediately returned to his old mistress the Duchesse de Choiseul. Thus abandoned, and in disgrace at court, the duchess betook herself to religion. She accompanied her husband to his government at Rouen, and devoted herself to good works. She took for her director M. Singlin, so famous in the history of Port Royal, and from that time began her new religious life. Till 1663 she chiefly lived in Normandy, when her husband died, and she came to Paris. There she became more and more Jansenist in opinion, and her piety and the remembrance of her influence during the disastrous days of the Fronde, and above all the tender love her brother, the great Condé, bore her, made her a conspicuous figure. The king pardoned her, and in every way showed the respect he had for her. She became the great protectress of the Jansenists; it was in her house that Arnauld, Nicole, and De Lane were protected; and to her influence must be in great part attributed the release of De Saoy from the Bastille, the introduction of Pomponne into the ministry and of Arnauld to the king. Her famous letters to the pope are part of the history of PORT ROYAL (q.v.), and as long as she lived the nuns of Port Royal des Champs were left in safety. Through the latter years of her life she had, despite the honour in which she was held, much to bear. Her elder son resigned his title and estates, and became a Jesuit under the name of the Abbé d'Orléans, while the younger, after leading a very debauched life, was killed, bravely leading the attack in the passage of the Rhine in 1673. As her health failed she devoted herself more and more to religion, and hardly ever left the convent of the Carmelites in which she had been educated. On her death in 1679 she was buried with great splendour by her brother Condé, and her heart, as she had directed, was sent to the nuns of that Port Royal des Champs which she had so greatly protected and defended. Her life is noteworthy, both from the harm she did in the turbulent days of the Fronde, though she acted, hardly knowing what she did, from love rather than from selfish ambition, and also from the greatness of her penitence, when her protection of Port Royal more than redeemed her fame, and gave her a title to the grateful remembrance of all who reverence true piety and learning more than the artificial glitter of the reign of the "grand monarch."

The chief authority for Madame de Longueville's life is a little book in two volumes by Villafra the Jansenist, published in 1738.

Cousin has devoted four volumes to her, which, though immensely diffuse, give a vivid picture of her time. Her connexion with Port Royal should be studied in Arnauld's *Mémoires*, and in the difficult histories of that institution.

LONGUS, the Greek romancer. Nothing is known of the life of the author of *Daphnis and Chloe*, and it is only inferred from some apparent imitations of the *Æthiopica* of Heliodorus that he wrote after the time of Theodorus. He may therefore be placed in the 5th century. His position in literature is interesting and not unimportant. He represents the romantic spirit of expiring classicism, the yearning of a highly artificial society for primitive simplicity, and the endeavour to create a corresponding ideal. The little idyl in the seventh edition of Dion Chrysostom is a beautiful example of this tendency three centuries before Longus, and the letters of Symeas, newly in his own day, attest a genuine feeling for nature and a country life. In its literary aspect, nevertheless, this movement has little in common with the return to pure nature which inspired a Wordsworth, or the realism of George Sand's delineations of the peasantry of Berri. Longus's style is rhetorical, and his shepherds and shepherdesses are wholly conventional. It is no small credit to him to have achieved so purely ideal a delineation with so little apparent affectation, and without any of the tediousness of almost all modern pastoral writers. If unable to blend the reality and idealism of the pastoral life as Shakespeare has done in *As You Like It* and *The Winter's Tale*, he has nevertheless imparted real human interest to a purely fanciful picture, and shows no little knowledge of human nature in his delineation of the growth of a passionate attachment between two innocent children. *Daphnis and Chloe* were probably the prototypes of Paul and Virginia; and, notwithstanding the naïveté of some details, the Greek has a decided advantage over the Frenchman in the simplicity and sincerity which constitute the true modesty of nature. As an analysis of feeling, *Daphnis and Chloe* makes a nearer approach to the modern novel than its chief rival among Greek erotic romances, the *Æthiopica* of Heliodorus, where the attraction mainly consists in the ingenious succession of incidents.

Longus has found an incomparable translator in Amyot, bishop of Auxerre, whose French version, as revised by Paul Louis Courmer, is better known than the original. It appeared in 1559, thirty-nine years before the publication of the Greek text at Florence by Alamanni. The chief subsequent editions are those by

Jungmann (Hann., 1603), Villosio (Paris, 1778, which first gave a standard text), Courmer (Rome, 1819, the first entirely complete edition), Scirei (Leyssac, 1835), and Percebois (Paris, 1866, pronounced by M. Pons the *se plus utile et accurate*). Pons's account of the literature and bibliography of the subject, appended to his edition of Courmer's version (1878), is very useful and complete. There are English translations by Thonibay, Cruge, and Le Gai, the last with omissions. The illustrated editions, generally of Amyot's version, are very numerous, and some are very beautiful. Pradon's designs are especially celebrated.

LONS-LE-SAULNIER, capital of the department of Jura, France, is situated at a distance of 275 miles by rail from Paris, on the Vallée, a small tributary of the Saône, about 820 feet above the sea-level, at the point where the Besançon, Lyons, and Châlon-sur-Saône railways converge. It is pleasantly surrounded by vine-clad hills from 300 to 500 feet in height, consisting of lower spurs of the Jura chain. It owes its name to its salt-guts, which have been used from a very remote period; the large quantities of ashes derived from the wood burnt in the process of evaporation are extensively utilized in agriculture. Since 1839 there has been an establishment for the use of the mineral waters. The principal industry of the place is the manufacture of sparkling wines, the climate growth being the best for this purpose. There is also a foundry, in addition to printing establishments, tanneries, distilleries, brush factories, and manufactures of carpets and tapestry. About a mile to the west of the town are the salt mines of Montmorot, employing one hundred and fifty workmen; the bed of rock salt, which lies at a depth of 100 feet, and is nearly 100 feet thick, yields about 5500 tons of pure salt yearly, 885 tons of sulphate of soda, and 300 tons of chloride of potassium. Lons-le-Saulnier possesses no buildings of special interest; one of the public squares contains a statue of Lecombe, and there is a museum containing Gallo-Roman antiquities and various works of art. The library, which like the museum is in the town hall, has 20,000 volumes. The population in 1876 was 11,371.

Lons-le-Saulnier, originally a Gallic town, was fortified by the Romans, destroyed by the barbarians, and, after its rebuilt and extended, belonged for a long time during the middle ages to the powerful house of Châlon, a branch branch of that of Burgundy. It was burned in 1461 by the English, and again in 1575, when it was seized by the duke of Longueville for Louis XIII. It was definitively French in 1571. It was then that the meeting between Ney and Napoleon took place, on the return of the latter from Elba, on March 21, 1815. Rouget de Lisle, the author of the *Marseillaise* Hymn, was born at Montmorot near this town.
